| 6.   | SUMMARY OVERVIEW OF RESULTS .....   | 181 |

*This Annex focuses on the assessment of potential impacts, which build on the results of the screening study explained in Annexes 3 to 5. The results of the screening do not constitute evaluations of individual substances to be carried out under the respective chemical legislations [Regulation (EC) No 1107/2009 on plant protection products and Regulation (EU) No 528/2012 on biocidal products] and in no way prejudge future decisions on active substances to be taken pursuant to these two Regulations. It would thus be erroneous to consider that the substances listed in Annex 5 are considered as endocrine disruptors within the meaning of the EU legislation. The methods and results presented in this Annex are to be interpreted as an estimation of the potential impacts.*

*The MCAs results are not concluding on any preferred option for setting scientific criteria to identify endocrine disruptors, but aim at providing additional information to decision makers with regards to the potential impacts*

*expected when implementing the criteria, after those would have been selected on the basis of science (two MCAs were performed: Options 1 to 4 under the current regulatory context, and Options A compared to Options B and C).*

*At a preliminary stage of the impact assessment it was anticipated that Option C should be discarded, nevertheless it was maintained for the analysis of the impacts for methodological reasons (see Section 4.2.3 of the main report and Annexes 6 and 7). Option C only applies to the PPP Regulation.*

## 1. INTRODUCTION

As set out in Annex 6, a Multi Criteria Analysis (MCA) was performed to compare Options 1 to 4 (Aspect I, EU criteria to identify endocrine disruptors (EDs)) and Options A to C (Aspect II, Approaches to regulatory decision making).

The options were compared under different scenarios in order to ascertain how different weights could have affected the overall ordering of the options:

1. **SCENARIO 1 - HOMOGENITY:** equal weights were assigned to all dimensions. For the weights of the MCA-criteria within each dimension, two sub-scenarios were considered:
  - i) **1/A:** within each dimension, equal weights were assigned to each MCA-criterion;
  - ii) **1/B:** within each dimension, higher weights were assigned to those MCA-criteria for which the availability of data/evidence was considered to be higher, while equal weights were assigned to those MCA-criteria for which data/evidence available was thought to be insufficient to discriminate.
2. **SCENARIO 2 - PRIORITY TO EVIDENCE:** different weights were assigned to the dimensions depending on the overall availability of data/evidence. Within each dimension, higher weights were assigned to those MCA-criteria for which the availability of data/evidence was considered to be higher, while equal weights were assigned to those MCA-criteria for which data/evidence available was thought to be insufficient to discriminate.
3. **SCENARIO 3 – PRIORITY TO HEALTH AND ENVIRONMENT:** equal weights were assigned to the dimensions Health and Environment, in light of the precautionary principle set out in article 191 of the Treaty on the Functioning of the EU. Decreasing weights were assigned to the remaining dimensions depending on the overall availability of data/evidence. Within each dimension, higher weights were assigned to those MCA-criteria for which the availability of data/evidence was considered to be higher, while equal weights were assigned to those MCA-criteria for which data/evidence available was thought to be insufficient to discriminate.
4. **SCENARIO 4 - HEALTH FIRST:** the highest weight was assigned to the dimension Health. The remaining dimensions were assigned a weight dependent on the overall availability of data/evidence. Within each dimension, higher weights were assigned to those MCA-criteria for which the availability of data/evidence was considered to be higher, while equal weights were assigned to those MCA-criteria for which data/evidence available was thought to be insufficient to discriminate.
5. **SCENARIO 5 – AIM: EXPOSURE ZERO:** this scenario examines what would be the effect considering a regulatory decision making which aims at completely reducing exposure to chemicals and as a consequence is based on hazard and does not

consider risk assessment. Scenarios 3 (priority to health and environment) and 4 (Health first) were used as starting points. Additionally, sub scenarios were developed which increase the weight assigned to Health. The resulting 4 sub-scenarios are described as follows:

- i) **5/A:** as scenario 3 + Hazard based decision making;
- ii) **5/B:** as scenario 3 + Hazard based decision making + increase of the weight assigned to Health (from 0,20 to 0,40) at the expenses of the other dimensions excluding Environment. Further, 50% of the overall weight for Human Health (0,40) was assigned to the criterion "hormone related diseases and disorders" and the remaining 50% was split equally between the other two MCA-criteria of the dimension Human Health (in all other scenarios considered, equal weights were assigned to the Human Health MCA-criteria as data/evidence available was considered to be insufficient to discriminate among them). This scenario is consequently giving the highest weight to ED related issues on human health (20%) and environment (13.4%), amounting to 33.4 % of the total weight.
- iii) **5/C:** as scenario 4 + Hazard based decision making;
- iv) **5/D:** as scenario 4 + Hazard based decision making + an increase of the weight assigned to Health (from 0,25 to 0,40) at the expenses of the other dimensions.

For the purpose of the sensitivity analysis, additional simulations were run under Scenario 5/B (Aim: exposure zero) in order to evaluate when the policy ranking of the options would change.

In this annex, the tabular results are presented:

- overview of weights assigned to the MCA criteria and dimensions according to the different scenarios considered (sensitivity analysis, Table 1);
- performance of the options 1,2,3 and 4, and options A, B, and C.
- weighted performance matrices (multiplication of the performance and weights), giving composite quantities which allow each policy option to be compared and ranked for each criterion (Sections 2 and 3);
- outranking matrices and policy ranking permutations. Outranking matrices summarise how each option compared against another for all possible pairs of policy options. Policy ranking permutations allow selecting the policy options which maximise pair-wise agreement - and minimise disagreement (Sections 4 and 5);
- summary overview of the results (Section 6).

**Table 1. Overview of weights assigned to the MCA criteria according to the different scenarios (sensitivity analysis)**

<sup>1</sup> Note that some criteria names have been abbreviated. See Table 1 in Annex 6 or Table 3 in the main report for complete titles for the criteria.

<sup>2</sup> Scenario 5/B, assigns 50% of the overall weight for Human Health (0,40) to "hormone related diseases and disorders" and split the remaining 50% equally between the other two MCA-criteria of Human Health. In all other scenarios, equal weights are assigned to these 3 MCA-criteria as data/evidence available was considered insufficient to discriminate among them. This scenario is thus giving the highest weight to ED related issues on human health (20%) and environment (13,4%).

<sup>6</sup> This sub scenario builds on 5C, which considers hazard, and translates into a different relative performance of options 2 and 3 with respect to the following MCA criteria linked directly to ED effects: hormone related diseases and disorders, and wildlife vertebrate populations (highlighted in grey). In addition, it increases the weight for Human Health (from 0,25 to 0,40) while decreasing the weights for all other dimensions.

<sup>8</sup> This sub scenario builds on 5A which considers hazard, and translates into a different relative performance of Option A with respect to the following MCA criteria, linked directly to ED effects: hormone related diseases and disorders, chemical quality of water, and wildlife vertebrate populations (highlighted in grey). In addition, it increases the weight for Human Health (from 0,20 to 0,40) at the expenses of the other dimensions excluding Environment.

<sup>10</sup> This sub scenario builds on 5C which considers hazard, and translates into a different relative performance of Option A with respect to the following MCA criteria, linked directly to ED effects: hormone related diseases and disorders, chemical quality of water, and wildlife vertebrate populations (highlighted in grey). In addition, it increases the weight for Human Health (from 0,25 to 0,40) while decreasing the weights for all other dimensions.

## 6. SUMMARY OVERVIEW OF RESULTS

The MCA was carried out by using a step-wise approach, because there were two sets of options to consider (see Annex 6, section 3.2).

The MCA methodology was first applied to Options 1 to 4 (Aspect I: setting scientific criteria to identify EDs) in order to get the policy rankings for these options under all scenarios. The same MCA methodology (including the same criteria, weights, and performance assessment method) was then applied to Options A to C (Aspect II: implementation of the ED criteria / approach to regulatory decision making), in order to get the corresponding policy rankings.

The results obtained for the two sets of options are summarised in the following Tables 38 and 39, where for each scenario considered, the corresponding best policy ranking of the options is given (e.g., for scenario 1/A, the corresponding policy ranking means that Option 4 is better than Option 2, which is in turn better than Option 3, being Option 1 the worst among the four considered).

**Table 40. Overview of results in terms of policy ranking of Options 1-4 (Aspect I: setting scientific criteria to identify EDs)**

| SENSITIVITY SCENARIO                | POLICY RANKING OF OPTIONS  |
|-------------------------------------|--|
| Scenario 1A – Homogeneity           | 4 > 2 > 3 > 1  |
| Scenario 1B – Homogeneity           | 4 > 2 > 3 > 1  |
| Scenario 2 – Priority to evidence   | 4 > 2 > 3 > 1  |
| Scenario 3 – Health and Environment | 4 > 2 > 3 > 1  |
| Scenario 4 – Health first           | 4 > 2 > 3 > 1  |
| Scenario 5A – Aim: exposure zero    | 4 > 2 > 3 > 1  |
| Scenario 5B – Aim: exposure zero *  | 4 > 2 > 3 > 1  |
| Scenario 5C – Aim: exposure zero    | 4 > 2 > 3 > 1  |
| Scenario 5D – Aim: exposure zero    | 4 > 2 > 3 > 1  |
| Overall ranking                     | WHO + potency (Option 4) ><br>> WHO (Option 2) ><br>> WHO + categories (Option 3) ><br>> Interim criteria (Option 1) |

\* The policy ranking remains unchanged when the weight assigned to the human health criteria "hormone related diseases and disorders" is increased to 25% with the weight for "food safety" and "transmissible diseases caused by lack of appropriate disinfectants or insecticides" set at 7,5% each

**Table 41. Overview of results in terms of policy ranking of Options A-C (Aspect II: implementation of the ED criteria / approach to regulatory decision making)**

| SENSITIVITY SCENARIO                | POLICY RANKING OF OPTIONS  |
|-------------------------------------|--|
| Scenario 1A – Homogeneity           | C > B > A  |
| Scenario 1B – Homogeneity           | C > B > A  |
| Scenario 2 – Priority to evidence   | C > B > A  |
| Scenario 3 – Health and Environment | C > B > A  |
| Scenario 4 – Health first           | C > B > A  |
| Scenario 5A – Aim: exposure zero    | C > B > A  |
| Scenario 5B – Aim: exposure zero *  | C > B > A  |
| Scenario 5C – Aim: exposure zero    | C > B > A  |
| Scenario 5D – Aim: exposure zero    | C > B > A  |
| Overall ranking                     | Alignment socio-economic considerations (Option C) ><br>> Alignment risk assessment (Option B) ><br>> no change to regulatory decision making (Option A) |

\* The policy ranking changes to B > A > C when the weight assigned to the human health criteria "hormone related diseases and disorders" in scenario (5B) is further increased to 25% with the weight for "food safety" and "transmissible diseases caused by lack of appropriate disinfectants or insecticides" set at 7,5% each.

The results illustrated in tables 40 and 41 show that for both sets of options, the policy ranking remains the same whatever scenario is being considered, which indicates consistent results in terms of policy ranking.

Regarding the EU criteria to identify EDs, and considering the current legislative framework, Option 4 (WHO definition + potency) ranks consistently as the best in the MCA, followed by Option 2 (WHO definition).

Regarding the approaches to regulatory decision making, the policy ranking obtained through the MCA clearly identifies Option C (alignment of PPP with BP by introducing socio-economic considerations) as the best option, followed by Option B (alignment of PPP with BP by introducing further elements of risk assessment).

It is worth mentioning that the consistency of the policy rankings with respect to a change in the weights assigned to the different dimensions/criteria (whose values depend on the scenarios considered), was evaluated via a sensitivity analysis carried out by considering alternative scenarios (see Table 1). Consistent results have been obtained regardless the different weights (i.e. "importance") assigned to the dimensions in these different scenarios. Total weights on human health and environment have been set at up to 60% (Scenario "Aim: exposure zero" 5B), including up to a total of 20% priority to hormone related diseases and a total of 13.4% priority on environment-ED related issues (chemical quality of water and wildlife). In addition, scenario 5 (aim: exposure zero) is also ranking the options in a more conservative way (performance of the options), since this is based only on exposure and does not consider risk assessment based decision making as in scenarios 1 to 4. In summary, also with 33.4% total weight on ED issues related to protection of human health and the environment, and a regulatory decision making based on hazard (no consideration of risk decision making), the best performing policy ranking identifies Option 4 and Option A as the best, followed by Option 2 and Option B, respectively.

Additional simulations were run under Scenario 5/B (Aim: exposure zero) assuming a different distribution of the weights assigned to the Human Health criteria (hormone related diseases and disorders 0,25; food safety 0,075; transmissible diseases caused by lack of appropriate disinfectants or insecticides 0,75). In total, this scenario assumes a protective hazard based regulatory decision making and puts a total weight of 38,4 % on MCA-criteria directly related to ED effects (25% on hormone related diseases and disorders, 6,7 % on chemical quality of water and 6,7% on wildlife vertebrate populations). The MCA-analysis resulted in a different policy ranking for Options A to C: Option C was performing the worst as the ranking was B > A > C. However, the policy ranking of Options 1 to 4 remained unchanged, and Option 4 remained the best, followed by Option 2.
