ENER 149 CLIMA 106 CONSOM 165 TRANS 159 AGRI 237 IND 97 ENV 394 CODEC 698

NOTE

From:	General Secretariat of the Council
To:	Permanent Representatives Committee
No. Cion doc.:	15120/1/16 ADD 1 ENER 417 CLIMA 168 CONSOM 298 TRANS 479 AGRI 650 IND 261 ENV 757 IA 130 CODEC 1802 REV 1
Subject:	ANNEXES to the Proposal for a Directive of the European Parliament and the Council on the promotion of the use of energy from renewable sources (recast)
	- General approach

Delegations will find in Annex the revised text of the Annexes. This document accompanies doc. 8697/4/17 REV 4, issued on 17 November.

Changes compared to the Commission proposal are indicated in **bold blue highlighted text**; deletions are marked with [].

Changes compared to the previous text are indicated in **bold underlined blue highlighted text**; deletions are marked with **[] or strikethrough blue highlighted text**.

To improve the readibility of the document, double strikethrough (sub)paragraphs from the original Commission proposal (*i.e.* (sub)paragraphs that are proposed to be deleted in their entirety) are now deleted, this is indicated by [____].

8697/17 ADD 1 REV 1 AT/st 1

ANNEX I

National overall targets for the share of energy from renewable sources in gross final consumption of energy in 2020¹

A.National overall targets

	Share of energy from renewable sources in gross final consumption of energy, 2005 (S ₂₀₀₅)	Target for share of energy from renewable sources in gross final consumption of energy, 2020 (S ₂₀₂₀)
Belgium	2,2 %	<u>13 %</u>
Bulgaria	9,4 %	<u>16 %</u>
Czech Republic	<u>6,1 %</u>	<u>13 %</u>
Denmark	<u>17,0 %</u>	<u>30 %</u>
Germany	<u>5,8 %</u>	<u>18 %</u>
Estonia	<u>18,0 %</u>	<u>25 %</u>
Ireland	<u>3,1 %</u>	<u>16 %</u>
Greece	<u>6,9 %</u>	<u>18 %</u>
Spain	<u>8,7 %</u>	20 %
France	<u>10,3 %</u>	23 %
⇒ Croatia ←	⇒ 12,6% ⇐	⇒ 20% ←
<u>Italy</u>	<u>5,2 %</u>	<u>17 %</u>

In order to be able to achieve the national objectives set out in this Annex, it is underlined that the State aid guidelines for environmental protection recognise the continued need for national mechanisms of support for the promotion of energy from renewable sources.

Cyprus	2,9 %	<u>13 %</u>
Latvia	<u>32,6 %</u>	40 %
Lithuania	<u>15,0 %</u>	23 %
Luxembourg	<u>0,9 %</u>	<u>11 %</u>
Hungary	4,3 %	<u>13 %</u>
Malta	0,0 %	<u>10 %</u>
Netherlands	2,4 %	<u>14 %</u>
<u>Austria</u>	23,3 %	<u>34 %</u>
Poland	7,2 %	<u>15 %</u>
Portugal	20,5 %	<u>31 %</u>
Romania	<u>17,8 %</u>	24 %
<u>Slovenia</u>	<u>16,0 %</u>	<u>25 %</u>
Slovak Republic	<u>6,7 %</u>	<u>14 %</u>
Finland	<u>28,5 %</u>	38 %
Sweden	<u>39,8 %</u>	<u>49 %</u>
United Kingdom	<u>1,3 %</u>	<u>15 %</u>

B.INDICATIVE TRAJECTORY

The indicative trajectory referred to in Article 3(2) shall consist of the following shares of energy from renewable sources:

 $S_{2005} + 0.20$ ($S_{2020} - S_{2005}$), as an average for the two-year period 2011 to 2012;

 $S_{2005} + 0.30$ ($S_{2020} - S_{2005}$), as an average for the two-year period 2013 to 2014;

S₂₀₀₅ + 0,45 (S₂₀₂₀ - S₂₀₀₅), as an average for the two-year period 2015 to 2016; and

S₂₀₀₅ + 0,65 (S₂₀₂₀ - S₂₀₀₅), as an average for the two-year period 2017 to 2018,

where

S₂₀₀₅ = the share for that Member State in 2005 as indicated in the table in part A,

and

S₂₀₂₀ = the share for that Member State in 2020 as indicated in the table in part A.

ANNEX II

Normalisation rule for accounting for electricity generated from hydropower and wind power

The following rule shall be applied for the purpose of accounting for electricity generated from hydropower in a given Member State:

 $(Q_{N(norm)})(C_N[(/(i)(N14))(Q_iC_i)]15)$ where:

N	=	reference year;
QN(norm)	=	normalised electricity generated by all hydropower plants of the Member State in year <i>N</i> , for accounting purposes;
Qi	=	the quantity of electricity actually generated in year <i>i</i> by all hydropower plants of the Member State measured in GWh, excluding production from pumped storage units using water that has previously been pumped uphill;
Ci	=	the total installed capacity, net of pumped storage, of all hydropower plants of the Member State at the end of year <i>i</i> , measured in MW.

The following rule shall be applied for the purpose of accounting for electricity generated from wind power in a given Member State:

$(Q_{N(norm)})((C_N\ C_{N\ 1}2)((/(i)(Nn))Q_i(/(j)(Nn))(C_j\ C_{j\ 1}2))) where:$

N	=	reference year;
QN(norm)	=	normalised electricity generated by all wind power plants of the Member State in year <i>N</i> , for accounting purposes;
Q_i	=	the quantity of electricity actually generated in year <i>i</i> by all wind power plants of the Member State measured in GWh;
C_j	=	the total installed capacity of all the wind power plants of the Member State at the end of year <i>j</i> , measured in MW;
n	=	4 or the number of years preceding year <i>N</i> for which capacity and production data are available for the Member State in question, whichever is lower.

ANNEX III

Energy content of $\frac{1}{2}$ fuels

Fuel	Energy content by	Energy content by
	weight (lower	volume (lower
	calorific value,	calorific value,
	MJ/kg)	MJ/l)
FUELS FROM BIOMASS AND/ OR BIOMASS PR	OCESSING OPERATION	ONS
Bio-Propane	46	24
Pure vegetable oil (oil produced from oil plants through pressing, extraction or comparable procedures, crude or refined but chemically unmodified)	37	34
Biodiesel - fatty acid methyl ester (methyl-ester produced from oil of biomass origin)	37	33
Biodiesel - fatty acid ethyl ester (ethyl-ester produced from oil of biomass origin)	38	34
Biogas that can be purified to natural gas quality	50	-
Hydrotreated (thermochemically treated with hydrogen) oil of biomass origin, to be used for replacement of diesel	44	34

Hydrotreated (thermochemically treated with hydrogen) oil of biomass origin, to be used for replacement of petrol	45	30
Hydrotreated (thermochemically treated with hydrogen) oil of biomass origin, to be used for replacement of jet fuel	44	34
Hydrotreated oil (thermochemically treated with hydrogen) of biomass origin, to be used for replacement of liquefied petroleum gas	46	24
Co-processed oil (processed in a refinery simultaneously with fossil fuel) of biomass or pyrolysed biomass origin to be used for replacement of diesel	43	36
Co-processed oil (processed in a refinery simultaneously with fossil fuel) of biomass or pyrolysed biomass origin, to be used to replace petrol	44	32
Co-processed oil (processed in a refinery simultaneously with fossil fuel) of biomass or pyrolysed biomass origin, to be used to replace jet fuel	43	33
Co-processed oil (processed in a refinery simultaneously with fossil fuel) of biomass or pyrolysed biomass origin, to be used to replace liquefied petroleum gas	46	23

RENEWABLE FUELS THAT CAN BE PRODUCED FROM VARIOUS RENEWABLE ENERGY SOURCES INCLUDING WHILE NOT LIMITED TO BIOMASS			
Methanol from renewable energy sources	20	16	
Ethanol from renewable energy sources	27	21	
Propanol from renewable energy sources	31	25	
Butanol from renewable energy sources	33	27	
Fischer-Tropsch diesel (a synthetic hydrocarbon or mixture of synthetic hydrocarbons to be used for replacement of diesel)	44	34	
Fischer-Tropsch petrol (a synthetic hydrocarbon or mixture of synthetic hydrocarbons produced from biomass, to be used for replacement of petrol)	44	33	
Fischer-Tropsch jet fuel (a synthetic hydrocarbon or mixture of synthetic hydrocarbons produced from biomass, to be used for replacement of jet fuel)	44	33	

Fischer-Tropsch liquefied petroleum gas (a synthetic hydrocarbon or mixture of synthetic hydrocarbons, to be used for replacement of liquefied petroleum gas	46	24
DME (dimethylether)	28	19
Hydrogen from renewable sources	120	-
ETBE (ethyl-tertio-butyl-ether produced on the basis of ethanol)	36 (of which 37% from renewable sources)	27 (of which 37% from renewable sources)
MTBE (methyl-tertio-butyl-ether produced on the basis of methanol)	35 (of which 22% from renewable sources)	26 (of which 22% from renewable sources)
TAEE (tertiary-amyl-ethyl-ether produced on the basis of ethanol)	38 (of which 29% from renewable sources)	29 (of which 29% from renewable sources)
TAME (tertiary-amyl-methyl-ether produced on the basis of ethanol)	36 (of which 18% from renewable sources)	28 (of which 18% from renewable sources)
THxEE (tertiary-hexyl-ethyl-ether produced on the basis of ethanol)	38 (of which 25% from renewable sources)	30 (of which 25% from renewable sources)
THxME (tertiary-hexyl-methyl-ether produced on the basis of ethanol)	38 of which 14% from renewable sources)	30 (of which 14% from renewable sources)
FOSSIL FUELS		
Petrol	43	32
Diesel	43	36

↓ 2009/28/EC

ANNEX IV

Certification of installers

The certification schemes or equivalent qualification schemes referred to in Article 18 ±4(3) shall be based on the following criteria:

- 1. The certification or qualification process shall be transparent and clearly defined by the Member State or the administrative body they appoint.
- 2. Biomass, heat pump, shallow geothermal and solar photovoltaic and solar thermal installers shall be certified by an accredited training programme or training provider.
- 3. The accreditation of the training programme or provider shall be effected by Member States or administrative bodies they appoint. The accrediting body shall ensure that the training programme offered by the training provider has continuity and regional or national coverage. The training provider shall have adequate technical facilities to provide practical training, including some laboratory equipment or corresponding facilities to provide practical training. The training provider shall also offer in addition to the basic training, shorter refresher courses on topical issues, including on new technologies, to enable lifelong learning in installations. The training provider may be the manufacturer of the equipment or system, institutes or associations.

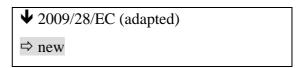

- 4. The training leading to installer certification or qualification shall include both theoretical and practical parts. At the end of the training, the installer must have the skills required to install the relevant equipment and systems to meet the performance and reliability needs of the customer, incorporate quality craftsmanship, and comply with all applicable codes and standards, including energy and eco-labelling.
- 5. The training course shall end with an examination leading to a certificate or qualification. The examination shall include a practical assessment of successfully installing biomass boilers or stoves, heat pumps, shallow geothermal installations, solar photovoltaic or solar thermal installations.
- 6. The certification schemes or equivalent qualification schemes referred to in Article 18 +4(3) shall take due account of the following guidelines:
 - (a) Accredited training programmes should be offered to installers with work experience, who have undergone, or are undergoing, the following types of training:
 - (i) in the case of biomass boiler and stove installers: training as a plumber, pipe fitter, heating engineer or technician of sanitary and heating or cooling equipment as a prerequisite;
 - (ii) in the case of heat pump installers: training as a plumber or refrigeration engineer and have basic electrical and plumbing skills (cutting pipe, soldering pipe joints, gluing pipe joints, lagging, sealing fittings, testing for leaks and installation of heating or cooling systems) as a prerequisite;

- (iii) in the case of a solar photovoltaic or solar thermal installer: training as a plumber or electrician and have plumbing, electrical and roofing skills, including knowledge of soldering pipe joints, gluing pipe joints, sealing fittings, testing for plumbing leaks, ability to connect wiring, familiar with basic roof materials, flashing and sealing methods as a prerequisite; or
- (iv) a vocational training scheme to provide an installer with adequate skills corresponding to a three years education in the skills referred to in point (a), (b) or (c) including both classroom and workplace learning.
- (b) The theoretical part of the biomass stove and boiler installer training should give an overview of the market situation of biomass and cover ecological aspects, biomass fuels, logistics, fire protection, related subsidies, combustion techniques, firing systems, optimal hydraulic solutions, cost and profitability comparison as well as the design, installation, and maintenance of biomass boilers and stoves. The training should also provide good knowledge of any European standards for technology and biomass fuels, such as pellets, and biomass related national and Community law.

- (c) The theoretical part of the heat pump installer training should give an overview of the market situation for heat pumps and cover geothermal resources and ground source temperatures of different regions, soil and rock identification for thermal conductivity, regulations on using geothermal resources, feasibility of using heat pumps in buildings and determining the most suitable heat pump system, and knowledge about their technical requirements, safety, air filtering, connection with the heat source and system layout. The training should also provide good knowledge of any European standards for heat pumps, and of relevant national and Community law. The installer should demonstrate the following key competences:
 - (i) a basic understanding of the physical and operation principles of a heat pump, including characteristics of the heat pump circle: context between low temperatures of the heat sink, high temperatures of the heat source, and the efficiency of the system, determination of the coefficient of performance (COP) and seasonal performance factor (SPF);
 - (ii) an understanding of the components and their function within a heat pump circle, including the compressor, expansion valve, evaporator, condenser, fixtures and fittings, lubricating oil, refrigerant, superheating and sub-cooling and cooling possibilities with heat pumps; and
 - (iii) the ability to choose and size the components in typical installation situations, including determining the typical values of the heat load of different buildings and for hot water production based on energy consumption, determining the capacity of the heat pump on the heat load for hot water production, on the storage mass of the building and on interruptible current supply; determine buffer tank component and its volume and integration of a second heating system.

- (d) The theoretical part of the solar photovoltaic and solar thermal installer training should give an overview of the market situation of solar products and cost and profitability comparisons, and cover ecological aspects, components, characteristics and dimensioning of solar systems, selection of accurate systems and dimensioning of components, determination of the heat demand, fire protection, related subsidies, as well as the design, installation, and maintenance of solar photovoltaic and solar thermal installations. The training should also provide good knowledge of any European standards for technology, and certification such as Solar Keymark, and related national and Community law. The installer should demonstrate the following key competences:
 - (i) the ability to work safely using the required tools and equipment and implementing safety codes and standards and identify plumbing, electrical and other hazards associated with solar installations;
 - (ii) the ability to identify systems and their components specific to active and passive systems, including the mechanical design, and determine the components' location and system layout and configuration;

- (iii) the ability to determine the required installation area, orientation and tilt for the solar photovoltaic and solar water heater, taking account of shading, solar access, structural integrity, the appropriateness of the installation for the building or the climate and identify different installation methods suitable for roof types and the balance of system equipment required for the installation; and
- (iv) for solar photovoltaic systems in particular, the ability to adapt the electrical design, including determining design currents, selecting appropriate conductor types and ratings for each electrical circuit, determining appropriate size, ratings and locations for all associated equipment and subsystems and selecting an appropriate interconnection point.
- (e) The installer certification should be time restricted, so that a refresher seminar or event would be necessary for continued certification.

ANNEX V

Rules for calculating the greenhouse gas impact of biofuels, bioliquids and their fossil fuel comparators

A.TYPICAL AND DEFAULT VALUES FOR BIOFUELS IF PRODUCED WITH NO NET CARBON EMISSIONS FROM LAND-USE CHANGE

Biofuel production pathway	Typical greenhouse gas emission saving	Default greenhouse gas emission saving
sugar beet ethanol	61 % ⇒ 67% ←	\$2 ⇒ 59 ← %
⇒ sugar beet ethanol (with biogas from slop, natural gas as process fuel in conventional boiler) ⇔	⇒ 77% ←	⇒ 73% ←
⇒ sugar beet ethanol (no biogas from slop, natural gas as process fuel in CHP plant*) ⇔	⇒ 73% ←	⇒ 68 % ←
⇒ sugar beet ethanol (with biogas from slop, natural gas as process fuel in CHP plant*) ←	⇒ 79 % ←	⇒ 76 % ←

⇒ sugar beet ethanol (no biogas from slop, lignite as process fuel in CHP plant *) ←	⇒ 58% ←	⇒ 46% ←
⇒ sugar beet ethanol (with biogas from slop, lignite as process fuel in CHP plant *) ⇔	⇒ 71% ←	⇒ 64% ←
wheat ethanol (process fuel not specified)	32 %	16 %
wheat ethanol (lignite as process fuel in CHP plant)	32 %	16 %
wheat ethanol (natural gas as process fuel in conventional boiler)	45 %	34 %
wheat ethanol (natural gas as process fuel in CHP plant)	53 %	47 %
wheat ethanol (straw as process fuel in CHP plant)	69 %	69 %
⇒ corn (maize) ethanol (natural gas as process fuel in conventional boiler) ←	⇒ 48 % ←	⇒ 40 % ←
corn (maize) ethanol, Community produced (natural gas as process fuel in CHP plant ⇒ * ←)	56 ⇒ 55 ⇔ %	49 ⇒ 48 % ←
⇒ corn (maize) ethanol (lignite as process fuel in CHP plant*) ←	⇒ 40 % ←	⇒ 28 % ←
⇒ corn (maize) ethanol (forest residues as process fuel in CHP plant*) ←	⇒ 69 % ←	⇒ 68 % ←
⇒ other cereals excluding maize ethanol (natural gas as process fuel in conventional boiler) ⇔	⇒ 47 % ←	⇒ 38 % ←
 ⇒ other cereals excluding maize ethanol (natural gas as process fuel in CHP plant *) < 	⇒ 53 % ←	⇒ 46 % ←
⇒ other cereals excluding maize ethanol (lignite as process fuel in CHP plant *) ←	⇒ 37 % ←	⇒ 24 % ←

⇒ other cereals excluding maize ethanol (forest residues as process fuel in CHP plant *) ←	⇒ 67 % ←	⇒ 67 % ←
sugar cane ethanol	⇒ 70 % ←	⇒ 70 % ⇔
the part from renewable sources of ethyltertio-butyl-ether (ETBE)	Equal to that of the ethanol production pathway used	
the part from renewable sources of tertiary-amyl-ethyl-ether (TAEE)	Equal to that of the eth pathway used	anol production
rape seed biodiesel	45 ⇒ 52 ← %	38 ⇒ 47 ← %
sunflower biodiesel	58 ⇒ 57 ← %	51 ⇒ 52 ← %
soybean biodiesel	40 ⇒ 55 ← %	31 ⇒ 50 ← %
palm oil biodiesel (⇒ open effluent pond ← process not specified)	36 ⇒ 38 ← %	19 ⇒ 25 ← %
palm oil biodiesel (process with methane capture at oil mill)	€2 ⇒ 57 ← %	56 ⇒ 51 ← %
waste ⇒ cooking vegetable or animal* oil biodiesel	88 ⇔ <mark>88</mark> ⇔ %	83 ⇔ 84 ← %
⇒ animal fats from rendering biodiesel ⇔ **	⇒ <mark>84</mark> % ←	⇒ 78 % ←
hydrotreated vegetable oil from rape seed	51%	47%
hydrotreated vegetable oil from sunflower	⇒ 58 ← 65 %	⇒ 54 ← 62 %
⇒ hydrotreated vegetable oil from soybean ←	⇒ 55% ←	⇒ 51 % ←
hydrotreated vegetable oil from palm oil (⇒ open effluent pond ⇔ process not specified)	40 %	⇒ 28 = 26 %
hydrotreated vegetable oil from palm oil (process with methane capture at oil mill)	⇒ 59 ← 68 %	⇒ 55 ← 65 %

⇒ hydrotreated oil from waste cooking oil ⇔	⇒ <mark>87</mark> % <i>←</i>	⇒ 83 % ←
⇒ hydrotreated oil from animal fats from rendering ** ←	⇒ 83 % ←	⇒ <mark>77</mark> % ←
pure vegetable oil from rape seed	⇒ 59 % ← 58%	57%
⇒ pure vegetable oil from sunflower ⇔	⇒ 65% ←	⇒ 64% ←
⇒ pure vegetable oil from soybean ⇔	⇒ <u>62 63</u> % ←	⇒ 61 % ⇔
⇒ pure vegetable oil from palm oil (open effluent pond) ←	⇒ 46 % ←	⇒ 36 % ←
⇒ pure vegetable oil from palm oil (process with methane capture at oil mill) ←	⇒ 65 % ←	⇒ 63 % ←
⇒ pure oil from waste cooking oil ←	⇒ 98 % ⇔	⇒ 98 % ←
biogas from municipal organic waste as compressed natural gas	80 %	73 %
biogas from wet manure as compressed natural gas	84 %	81 %
biogas from dry manure as compressed natural gas	86 %	82 %

(**) Applies only to biofuels produced from animal by-products classified as category 1 and 2 material in accordance with Regulation (EC) No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules on animal by-products not intended for human consumption for which emissions related to hygenisation as part of the rendering are not considered (12)

-

Not including animal oil produced from animal by products classified as category 3 material in accordance with Regulation (EC)

No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules on animal by products
not intended for human consumption

new			

(*) Default values for processes using CHP are valid only if ALL the process heat is supplied by CHP.

B.ESTIMATED TYPICAL AND DEFAULT VALUES FOR FUTURE BIOFUELS THAT WERE NOT ON THE MARKET OR WERE ON THE MARKET ONLY IN NEGLIGIBLE QUANTITIES IN JANUARY 2008 ≥ 2016 ⟨ , IF PRODUCED WITH NO NET CARBON EMISSIONS FROM LAND-USE CHANGE

the part from renewable sources of methyl-tertio-butyl-ether (MTBE)	Equal to that of the methal used	nol production pathway

C.*METHODOLOGY*

1.	Greenhouse gas emissions from the production and use of transport fuels, biofuels and bioliquids
sh	nall be calculated as ☒ follows ☒:

□ new

(a) greenhouse gas emissions from the production and use of biofuels shall be calculated as:

$$E = e_{ec} + e_l + e_p + e_{td} + e_u - e_{sca} - e_{ccs} - e_{ccr} - e_{ee},$$

where

E	=	total emissions from the use of the fuel;
e ec	=	emissions from the extraction or cultivation of raw materials;
eı	=	annualised emissions from carbon stock changes caused by land-use change;
e_p	=	emissions from processing;
e_{td}	=	emissions from transport and distribution;
e_u	=	emissions from the fuel in use;
esca	=	emission savings from soil carbon accumulation via improved agricultural management;
eccs	=	emission savings from carbon capture and geological storage; ☒ and ☒
e_{ccr}	=	emission saving from carbon capture and replacement.; and
Cee		emission saving from excess electricity from cogeneration.

Emissions from the manufacture of machinery and equipment shall not be taken into account.

□ new

(b) Greenhouse gas emissions from the production and use of bioliquids shall be calculated as for biofuels (E), but with the extension necessary for including the energy conversion to electricity and/or heat and cooling produced, as follows:

(i) Energy installations delivering only heat:

$$EC_h = \frac{E}{\eta_h}$$

(ii) For energy installations delivering only electricity:

$$EC_{el} = \frac{E}{\eta_{el}}$$

where

EC h,el = Total greenhouse gas emissions from the final energy commodity.

E =Total greenhouse gas emissions of the bioliquid before end-conversion.

 η_{el} = The electrical efficiency, defined as the annual electricity produced divided by the annual bioliquid input based on its energy content.

 η_h = The heat efficiency, defined as the annual useful heat output divided by the annual bioliquid input based on its energy content.

(iii) For the electricity or mechanical energy coming from energy installations delivering useful heat together with electricity and/or mechanical energy:

$$EC_{el} = \frac{E}{\eta_{el}} \left(\frac{C_{el} \cdot \eta_{el}}{C_{el} \cdot \eta_{el} + C_h \cdot \eta_h} \right)$$

(iv) For the useful heat coming from energy installations delivering heat together with electricity and/or mechanical energy:

$$EC_h = \frac{E}{\eta_h} \left(\frac{C_h \cdot \eta_h}{C_{el} \cdot \eta_{el} + C_h \cdot \eta_h} \right)$$

where:

 $EC_{h,el}$ = Total greenhouse gas emissions from the final energy commodity.

E =Total greenhouse gas emissions of the bioliquid before end-conversion.

 η_{el} = The electrical efficiency, defined as the annual electricity produced divided by the annual fuel input based on its energy content.

 η_h = The heat efficiency, defined as the annual useful heat output divided by the annual fuel input based on its energy content.

C_{el} = Fraction of exergy in the electricity, and/or mechanical energy, set to 100 % (C_{el} = 1).

C_h = Carnot efficiency (fraction of exergy in the useful heat).

The Carnot efficiency, Ch, for useful heat at different temperatures is defined as:

$$C_h = \frac{T_h - T_0}{T_h}$$

where

T_h = Temperature, measured in absolute temperature (kelvin) of the useful heat at point of delivery.

 T_0 = Temperature of surroundings, set at 273 kelvin (equal to 0 °C)

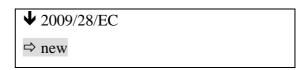

For T_h , < 150 °C (423.15 kelvin), C_h can alternatively be defined as follows:

C_h = Carnot efficiency in heat at 150 °C (423.15 kelvin), which is: 0.3546

For the purposes of this calculation, the following definitions shall apply:

(a)	"cogeneration"	shall mean the	simultaneous	generation	in one	process	of thermal	energy	and
electric	ity and/or mech	hanical energy;							

- (b) "useful heat" shall mean heat generated to satisfy an economical justifiable demand for heat, for heating and cooling purposes;
- (c) "economically justifiable demand" shall mean the demand that does not exceed the needs for heat or cooling and which would otherwise be satisfied at market conditions.

2. Greenhouse gas emissions from ⇒ biofuels and bioliquids shall be expressed as follows: ⇐ fuels, E, shall be expressed in terms of grams of CO₂ equivalent per MJ of fuel, gCO₂eq/MJ.

↓ new

- (a) greenhouse gas emissions from biofuels, E, shall be expressed in terms of grams of CO₂ equivalent per MJ of fuel, gCO_{2eq} /MJ.
- (b) greenhouse gas emissions from bioliquids, EC, in terms of grams of CO₂ equivalent per MJ of final energy commodity (heat or electricity), gCO_{2eq} /MJ.

When heating and cooling are co-generated with electricity emissions shall be allocated between heat and electricity (as under 1(b)) irrespective if the heat is used for actual heating purposes or for cooling³.

Where the greenhouse gas emissions from the extraction or cultivation of raw materials e_{ec} are expressed in unit g CO_{2eq}/dry-ton of feedstock the conversion to grams of CO₂ equivalent per MJ of fuel, gCO_{2eq} /MJ shall be calculated as follows;

$$e_{ec} fuel_a \left[\frac{gCO_2 eq}{MJ \ fuel} \right]_{ec} \ = \frac{e_{ec} \ feedstock_a \left[\frac{gCO_2 eq}{t_{dry}} \right]}{LHV_a \left[\frac{MJ \ feedstock}{t \ dry \ feedstock} \right]} * Fuel \ feedstock \ factor_a * Allocation \ factor \ fuel_a$$

where

$$Allocation\ factor\ fuel_a = \left[\frac{\textit{Energy in fuel}}{\textit{Energy fuel} + \textit{Energy in co-products}}\right]$$

Fuel feedstock factor_a = [Ratio of M] feedstock required to make 1 M] fuel]

Emissions per dry-ton feedstock shall be calculated as follows:

$$e_{sc}feedstock_{a}\left[\frac{gCO_{2}sq}{t_{dry}}\right] = \frac{e_{sc}feedstock_{a}\left[\frac{gCO_{2}sq}{t_{moist}}\right]}{(1-moisture\ content)}$$

Heat or waste heat is used to generate cooling (chilled air or water) through absorption chillers. Therefore, it is appropriate to calculate only the emissions associated to the heat produced per MJ of heat, irrespectively if the end-use of the heat is actual heating or cooling via absorption chillers.

↓ 2009/28/EC (adapted)

- 3. By derogation from point 2, for transport fuels, values calculated in terms of gCO_{2eq}/MJ may be adjusted to take into account differences between fuels in useful work done, expressed in terms of km/MJ. Such adjustments shall be made only where evidence of the differences in useful work done is provided.

↓ new

(a) greenhouse gas emission savings from biofuels:

♦ 2009/28/EC
⇒ new

 $SAVING = \Rightarrow (E_{F(t)} - E_B)/E_{F(t)} \Leftrightarrow \frac{(E_F - E_B)/E_F}{}$

where

E_B	1	total emissions from the biofuel; and	
$E_{F(t)}$	•	total emissions from the fossil fuel comparator ⇒ for transport □	

new

(b) greenhouse gas emission savings from heat and cooling, and electricity being generated from bioliquids:

 $SAVING = (EC_{F(h\&c,el,)} - EC_{B(h\&c,el)}/EC_{F(h\&c,el)},$

where

 $EC_{B(h\&c,el)}$ = total emissions from the heat or electricity; and

 $EC_{F(h\&c,el)}$ = total emissions from the fossil fuel comparator for useful heat or electricity.

5.4. The greenhouse gases taken into account for the purposes of point 1 shall be CO₂, N₂O and CH₄. For the purpose of calculating CO₂ equivalence, those gases shall be valued as follows:

CO ₂	:	1
N ₂ O	:	296 ⇒ 298 ⇔
CH ₄	:	23 ⇒ 25 ⇔

6.5. Emissions from the extraction or cultivation of raw materials, e_{cc} , shall include emissions from the extraction or cultivation process itself; from the collection, \Rightarrow drying and storage \Leftrightarrow of raw materials; from waste and leakages; and from the production of chemicals or products used in extraction or cultivation. Capture of CO₂ in the cultivation of raw materials shall be excluded. Certified reductions of greenhouse gas emissions from flaring at oil production sites anywhere in the world shall be deducted. Estimates of emissions from \Rightarrow agriculture biomass \Leftrightarrow cultivation may be derived from the use of \Rightarrow regional \Leftrightarrow averages \Rightarrow for cultivation emissions included in the reports referred to in Article 28 (4) \blacksquare or the information on the disaggregated default values for cultivation emissions included in this Annex, as an alternative to using actual values. In absence of relevant information in the before mentioned reports it is allowed to calculate averages based on local farming practises based for instance on data of a group of farms \Leftrightarrow ealeulated for smaller geographical areas than those used in the calculation of the default values, as an alternative to using actual values.

Û	new
Û	new

6. For the purposes of the calculation referred to in point [] 1, sub-point (a), emission savings from improved agriculture management e_{sca}, such as shifting to reduced or zero-tillage, improved crop/rotation, the use of cover crops, including crop residue management, and the use of organic soil improver (e.g. compost, manure fermentation digestate), shall be taken into account only if solid and verifiable evidence is provided that the soil carbon has increased or that it is reasonable to expect to have increased over the period in which the raw materials concerned were cultivated while taking into account the emissions where such practices lead to increased fertiliser and herbicide use⁴.

8697/17 ADD 1 REV 1 AT/st 30
ANNEX V DGE 2B **EN**

Measurements of soil carbon can constitute such evidence, e.g. by a first measurement in advance of the cultivation and subsequent ones at regular intervals several years apart. In such case, before the second measurement is available, increase in soil carbon would be estimated on the basis of representative experiments or soil models. From the second measurement onwards, the measurements would constitute the basis for determining the existence of an increase in soil carbon and its magnitude.

♦ 2015/1513 Art. 2.13 and Annex II.1

7. Annualised emissions from carbon stock changes caused by land-use change, e_l, shall be calculated by dividing total emissions equally over 20 years. For the calculation of those emissions, the following rule shall be applied:

$$e_1 = (CS_R - CS_A) \times 3,664 \times 1/20 \times 1/P - e_B,5$$

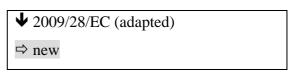

where

eı	=	annualised greenhouse gas emissions from carbon stock change due to land-use change (measured as mass (grams) of CO ₂ -equivalent per unit of biofuel or bioliquid energy (megajoules)). 'Cropland' and 'perennial cropland' shall be regarded as one land use;
CS _R	=	the carbon stock per unit area associated with the reference land-use (measured as mass (tonnes) of carbon per unit area, including both soil and vegetation). The reference land-use shall be the land-use in January 2008 or 20 years before the raw material was obtained, whichever was the later;
CSA	=	the carbon stock per unit area associated with the actual land-use (measured as mass (tonnes) of carbon per unit area, including both soil and vegetation). In cases where the carbon stock accumulates over more than one year, the value attributed to CS _A shall be the estimated stock per unit area after 20 years or when the crop reaches maturity, whichever the earlier;
P	=	the productivity of the crop (measured as biofuel or bioliquid energy per unit area per year) and
e _B	=	bonus of 29 gCO _{2eq} /MJ biofuel or bioliquid if biomass is obtained from restored degraded land under the conditions provided for in point 8.

The quotient obtained by dividing the molecular weight of CO2 (44,010 g/mol) by the molecular weight of carbon (12,011 g/mol) is equal to 3,664.

⁶ Cropland as defined by IPCC.

Perennial crops are defined as multi-annual crops, the stem of which is usually not annually harvested such as short rotation coppice and oil palm.

- 8. The bonus of 29 gCO_{2eq}/MJ shall be attributed if evidence is provided that the land:
 - (a) was not in use for agriculture or any other activity in January 2008; and
 - (b) falls into one of the following categories:
 - (i) ☒ is ☒ severely degraded land, including such land that was formerly in agricultural use.;
 - (ii) heavily contaminated land.

The bonus of 29 gCO_{2eq}/MJ shall apply for a period of up to $\frac{10}{10} \Rightarrow 20 \Leftrightarrow$ years from the date of conversion of the land to agricultural use, provided that a steady increase in carbon stocks as well as a sizable reduction in erosion phenomena for land falling under ($\frac{1}{2}$ b) are ensured and that soil contamination for land falling under ($\frac{1}{2}$) is reduced.

- 9. The categories referred to in point 8(b) are defined as follows:
- (a) 'severely Severely degraded land' means land that, for a significant period of time, has either been significantly salinated or presented significantly low organic matter content and has been severely eroded;
- (b) 'heavily contaminated land' means land that is unfit for the cultivation of food and feed due to soil contamination.

Such land shall include land that has been the subject of a Commission decision in accordance with the fourth subparagraph of Article 18(4).

10. The Commission shall $\frac{\text{adopt}}{\text{ED}}$ review \bigcirc , by 31 December $\frac{2009}{\text{ED}}$ \Rightarrow 2020 \rightleftharpoons , guidelines for the calculation of land carbon stocks drawing on the 2006 IPCC Guidelines for National Greenhouse Gas Inventories — volume $4 \Rightarrow$ and in accordance with the Regulation (EU) No $\frac{525}{2013}$ and the Regulation (INSERT THE NO AFTER THE ADOPTION $\stackrel{10}{\text{ED}}$) \rightleftharpoons . The Commission guidelines shall serve as the basis for the calculation of land carbon stocks for the purposes of this Directive.

11. Emissions from processing, e_p , shall include emissions from the processing itself; from waste and leakages; and from the production of chemicals or products used in processing including the carbon dioxide emissions corresponding to the carbon contents of fossil inputs, whether or not actually combusted in the process.

In accounting for the consumption of electricity not produced within the fuel production plant, the greenhouse gas emission intensity of the production and distribution of that electricity shall be assumed to be equal to the average emission intensity of the production and distribution of electricity in a defined region. By derogation from this rule, producers may use an average value for an individual electricity production plant for electricity produced by that plant, if that plant is not connected to the electricity grid.

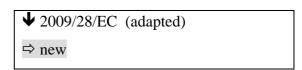

⁸ Commission Decision of 10 June 2010 (2010/335/EU) on guidelines for the calculation of land carbon stocks for the purpose of Annex V to Directive 2009/28/EC, OJ L 151 17.06.2010.

⁹ Regulation (EU) 525/2013 of the European Parliament and of the Council of 21 may 2013 on a mechanism for monitoring and reporting greenhouse gas emissions and for reporting other information at national and Union level relevant to climate change and repealing Decision No 280/2004/EC, OJ L 165/13, 18.06.2013

Regulation of the European Parliament and of the Council (INSERT THE DATE OF ENTRY INTO FORCE OF THIS REGULATION) on the inclusion of greenhouse gas emissions and removals from land use, land use change and forestry into the 2030 climate and energy framework and amending Regulation No 525/2013 of the European Parliament and the Council on a mechanism for monitoring and reporting greenhouse gas emissions and other information relevant to climate change.

Emissions from processing shall include emissions from drying of interim – products and materials where relevant.

- 12. Emissions from transport and distribution, e_{td} , shall include emissions from the transport and storage of raw and semi-finished materials and from the storage and distribution of finished materials. Emissions from transport and distribution to be taken into account under point ≤ 5 shall not be covered by this point.
- 13. Emissions from of the fuel in use, e_u , shall be taken to be zero for biofuels and bioliquids.
- \Rightarrow Emissions on non-CO₂ greenhouse gases (N₂O and CH₄) of the fuel in use shall be included in the e_u factor for bioliquids. \Leftarrow
- 14. Emission saving from carbon capture and geological storage e_{ccs} , that have not already been accounted for in e_p , shall be limited to emissions avoided through the capture and \Rightarrow storage \Leftrightarrow sequestration of emitted CO₂ directly related to the extraction, transport, processing and distribution of fuel \Rightarrow if stored in compliance with Directive 2009/31/EC on the geological storage of carbon dioxide \Leftrightarrow .

15. Emission saving from carbon capture and replacement, $e_{ccr} \Rightarrow$, shall be related directly to the production of biofuel or bioliquid they are attributed to, and \Leftrightarrow shall be limited to emissions avoided through the capture of CO₂ of which the carbon originates from biomass and which is used $\fbox{-}$ to replace fossil-derived CO₂ used in commercial products and services to replace fossil-derived CO₂.

new

16. Where a cogeneration unit – providing heat and/ or electricity to a fuel production process for which emissions are being calculated – produces excess electricity and/or excess useful heat, the greenhouse gas emissions shall be divided between the electricity and the useful heat according to the temperature of the heat (which reflects the usefulness (utility) of the heat). The allocation factor, called Carnot efficiency C_h, is calculated as follows for useful heat at different temperatures:

$$C_h = \frac{T_h - T_0}{T_h}$$

where

T_h = Temperature, measured in absolute temperature (kelvin) of the useful heat at point of delivery.

 T_0 = Temperature of surroundings, set at 273 kelvin (equal to 0°C)

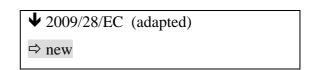

For T_h, < 150°C (423.15 kelvin), C_h can alternatively be defined as follows:

C_h = Carnot efficiency in heat at 150 °C (423.15 kelvin), which is: 0.3546

For the purposes of this calculation, the actual efficiencies shall be used, defined as the annual mechanical energy, electricity and heat produced respectively divided by the annual energy input.

For the purposes of this calculation, the following definitions shall apply:

- (a) "cogeneration" shall mean the simultaneous generation in one process of thermal energy and electrical and/or mechanical energy;
- (b) "useful heat" shall mean heat generated to satisfy an economical justifiable demand for heat, for heating or cooling purposes;
- (c) "economically justifiable demand" shall mean the demand that does not exceed the needs for heat or cooling and which would otherwise be satisfied at market conditions.

16. Emission saving from excess electricity from cogeneration, e,, shall be taken into account in relation to the excess electricity produced by fuel production systems that use cogeneration except where the fuel used for the cogeneration is a co-product other than an agricultural crop residue. In accounting for that excess electricity, the size of the cogeneration unit shall be assumed to be the minimum necessary for the cogeneration unit to supply the heat that is needed to produce the fuel. The greenhouse gas emission saving associated with that excess electricity shall be taken to be equal to the amount of greenhouse gas that would be emitted when an equal amount of electricity was generated in a power plant using the same fuel as the cogeneration unit.

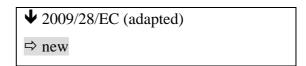

- 17. Where a fuel production process produces, in combination, the fuel for which emissions are being calculated and one or more other products (co-products), greenhouse gas emissions shall be divided between the fuel or its intermediate product and the co-products in proportion to their energy content (determined by lower heating value in the case of co-products other than electricity ⇒ and heat ⇔). ⇒ The greenhouse gas intensity of excess useful heat or excess electricity is the same as the greenhouse gas intensity of heat or electricity delivered to the fuel production process and is determined from calculating the greenhouse intensity of all inputs and emissions, including the feedstock and CH₄ and N₂O emissions, to and from the cogeneration unit, boiler or other apparatus delivering heat or electricity to the fuel production process. In case of cogeneration of electricity and heat the calculation is performed following point 16. ⇔
- 18. For the purposes of the calculation referred to in point 17, the emissions to be divided shall be $e_{cc} + e_r + \text{those fractions of } e_p$, e_{cc} and $e_{cc} \Rightarrow e_{ec} + e_1 + e_{sca} + \text{those fractions of } e_p$, e_{td} , e_{ccs} , and $e_{ccr} \Leftrightarrow \text{that take place up to and including the process step at which a co-product is produced. If any allocation to co-products has taken place at an earlier process step in the life-cycle, the fraction of those emissions assigned in the last such process step to the intermediate fuel product shall be used for this purpose instead of the total of those emissions.$

new		

In the case of biofuels and bioliquids, all co-products [], shall be taken into account for the purposes of that calculation. No emissions shall be allocated to wastes and residues. Co-products that have a negative energy content shall be considered to have an energy content of zero for the purpose of the calculation.

Wastes and residues, including tree tops and branches, straw, husks, cobs and nut shells, and residues from processing, including crude glycerine (glycerine that is not refined) and bagasse, shall be considered to have zero life-cycle greenhouse gas emissions up to the process of collection of those materials irrespectively of whether they are processed to interim products before being transformed into the final product.

In the case of fuels produced in refineries, other than the combination of processing plants with boilers or cogeneration units providing heat and/or electricity to the processing plant, the unit of analysis for the purposes of the calculation referred to in point 17 shall be the refinery.

In the case of biofuels and bioliquids, all co-products, including electricity that does not fall under the scope of point 16, shall be taken into account for the purposes of that calculation, except for agricultural crop residues, including straw, bagasse, husks, cobs and nut shells. Co-products that have a negative energy content shall be considered to have an energy content of zero for the purpose of the calculation.

Wastes, agricultural crop residues, including straw, bagasse, husks, cobs and nut shells, and residues from processing, including crude glycerine (glycerine that is not refined), shall be considered to have zero life-cycle greenhouse gas emissions up to the process of collection of those materials.

In the case of fuels produced in refineries, the unit of analysis for the purposes of the calculation referred to in point 17 shall be the refinery.

19. For biofuels, for the purposes of the calculation referred to in point 43, the fossil fuel comparator $\not \to E_{F(t)} \Leftrightarrow$ shall be the latest available actual average emissions from the fossil part of petrol and diesel consumed in the Community as reported under Directive 98/70/EC. If no such data are available, the value used shall be 83,8 \Rightarrow 94 \Leftrightarrow gCO_{2eq}/MJ.

For bioliquids used for electricity production, for the purposes of the calculation referred to in point 43, the fossil fuel comparator $EC_{F(e)}$ shall be $94 \Rightarrow 183 \Leftarrow gCO_{2eq}/MJ$.

For bioliquids used for \Rightarrow the production of useful \Leftrightarrow heat \Rightarrow , as well as for the production of heating and/or cooling \Leftrightarrow production, for the purposes of the calculation referred to in point 43, the fossil fuel comparator $E_{\mathsf{F}}^{\mathsf{C}} \Rightarrow (h\&c) \Leftrightarrow \text{shall be } \not\rightrightarrows \Rightarrow 80 \Leftrightarrow gCO_{2eq}/MJ$.

For bioliquids used for cogeneration, for the purposes of the calculation referred to in point 4, the fossil fuel comparator E_F-shall be 85 gCO_{2eq}/MJ.

D.DISAGGREGATED DEFAULT VALUES FOR BIOFUELS AND BIOLIQUIDS

Disaggregated default values for cultivation: e_{ec} as defined in part C of this Annex \boxtimes including soil N_2O emissions \boxtimes

	Case 3	Close digestate	243%	235%

-

¹¹ The values for biogas production from manure include negative emissions for emissions saved from raw manure management. The value of esca considered is equal to -45 gCO2eq./MJ manure used in anaerobic digestion

Open storage of digestate accounts for additional emissions of methane and N2O. The magnitude of these emissions changes with ambient conditions, substrate types and the digestion efficiency (see chapter 5 for more details).

¹³ Close storage means that the digestate resulting from the digestion process is stored in a gas-tight tank and the additional biogas released during storage is considered to be recovered for production of additional electricity or biomethane. No emissions of GHG are included in this process.

		Open digestate	38%	14%
	Case 3	Close digestate	76%	66%

^{*} Case 1 refers to pathways in which power and heat required in the process are supplied by the CHP engine itself.

Case 2 refers to pathways in which the electricity required in the process is taken from the grid and the process heat is supplied by the CHP engine itself. In some Member States, operators are not allowed to claim the gross production for subsidies and Case 1 is the more likely configuration.

_

Maize whole plant should be interpreted as maize harvested as fodder and ensiled for preservation.

Case 3 refers to pathways in which the electricity required in the process is taken from the grid and the process heat is supplied by a biogas boiler. This case applies to some installations in which the CHP engine is not on-site and biogas is sold (but not upgraded to biomethane).

This category includes the following categories of technologies for biogas upgrade to biomethane: Pressure Swing Adsorption (PSA), Pressure Water Scrubbing (PWS), Membranes, Cryogenic, and Organic Physical Scrubbing (OPS). It includes an emission of 0.03 MJCH4/MJbiomethane for the emission of methane in the off-gases.

This category includes the following categories of technologies for biogas upgrade to biomethane: Pressure Water Scrubbing (PWS) when water is recycled, Pressure Swing Adsorption (PSA), Chemical Scrubbing, Organic Physical Scrubbing (OPS), Membranes and Cryogenic upgrading. No methane emissions are considered for this category (the methane in the off-gas is combusted, if any).

^{*}The greenhouse gas emission savings for biomethane only refer to compressed biomethane relative to the fossil fuel comparator for transport of 94 gCO2 eq./MJ.

B. METHODOLOGY

- 1. Greenhouse gas emissions from the production and use of biomass fuels, shall be calculated as follows:
 - (a) Greenhouse gas emissions from the production and use of biomass fuels before conversion into electricity, heating and cooling, shall be calculated as:

$$E = e_{ec} + e_1 + e_p + e_{td} + e_u - e_{sca} - e_{ccs} - e_{ccr}$$

Where

E = total emissions from the production of the fuel before energy conversion;

 e_{ec} = emissions from the extraction or cultivation of raw materials;

 e_l = annualised emissions from carbon stock changes caused by land use change;

 e_p = emissions from processing;

 e_{td} = emissions from transport and distribution;

 e_u = emissions from the fuel in use;

 e_{sca} = emission savings from soil carbon accumulation via improved agricultural management;

 e_{ccs} = emission savings from carbon capture and geological storage; and

 e_{ccr} = emission savings from carbon capture and replacement.

Emissions from the manufacture of machinery and equipment shall not be taken into account.

(b) In case of co-digestion of different substrates in a biogas plant for the production of biogas or biomethane the typical and default values of greenhouse gas emissions shall be calculated as:

$$E = \sum_{1}^{n} S_n \cdot E_n$$

where

E = GHG emissions per MJ biogas or biomethane produced from co-digestion of the defined mixture of substrates

 S_n = Share of feedstock n in energy content

 E_n = Emission in gCO₂/MJ for pathway n as provided in Part D of this document*

$$S_n = \frac{P_n \cdot W_n}{\sum_{1}^{n} P_n \cdot W_n}$$

where

P_n = energy yield [MJ] per kilogram of wet input of feedstock n**

 W_n = weighting factor of substrate n defined as:

$$W_n = \frac{I_n}{\sum_{1}^{n} I_n} \cdot \left(\frac{1 - AM_n}{1 - SM_n}\right)$$

where:

 I_n = Annual input to digester of substrate n [tonne of fresh matter]

 $AM_n = Average annual moisture of substrate n [kg water / kg fresh matter]$

 $SM_n = Standard moisture for substrate n***.$

* For animal manure used as substrate, a bonus of 45 gCO_{2eq}/MJ manure (-54 kg CO_{2eq}/t fresh matter) is added for improved agricultural and manure management.

** The following values of P_n shall be used for calculating typical and default values:

P(Maize): 4.16 [MJbiogas/kg wet maize @ 65 % moisture]

P(Manure): 0.50 [MJbiogas/kg wet manure @ 90 % moisture]

P(Biowaste) 3.41 [MJbiogas/kg wet biowaste @ 76 % moisture]

***The following values of the standard moisture for substrate SMn shall be used:

SM(Maize): 0.65 [kg water/kg fresh matter]

SM(Manure): 0.90 [kg water/kg fresh matter]

SM(Biowaste): 0.76 [kg water/kg fresh matter]

(c) In case of co-digestion of n substrates in a biogas plant for the production of electricity or biomethane, actual greenhouse gas emissions of biogas and biomethane are calculated as follows:

$$E = \sum_{1}^{n} S_n \cdot \left(e_{ec,n} + e_{td,feedstock,n} + e_{l,n} - e_{sca,n} \right) + e_p + e_{td,product} + e_u - e_{ccs} - e_{ccr}$$

where

E= total emissions from the production of the biogas or biomethane before energy conversion;

Sn = Share of feedstock n, in fraction of input to the digester

 $e_{ec,n}$ = emissions from the extraction or cultivation of feedstock n;

 $e_{td,feedstock,n}$ = emissions from transport of feedstock n to the digester;

 $e_{l,n}$ = annualised emissions from carbon stock changes caused by land use change, for feedstock n;

 e_{sca} = emission savings from improved agricultural management of feedstock n*;

 e_p = emissions from processing;

 $e_{td,product}$ = emissions from transport and distribution of biogas and/or biomethane;

 e_u = emissions from the fuel in use, that is greenhouse gases emitted during combustion;

 e_{ccs} = emission savings from carbon capture and geological storage; and

 e_{ccr} = emission savings from carbon capture and replacement.

* For e_{sca} a bonus of 45 gCO_{2eq.} / MJ manure shall be attributed for improved agricultural and manure management in case animal manure is used as a substrate for the production of biogas and biomethane.

- (d) Greenhouse gas emissions from the use of biomass fuels in producing electricity, heating and cooling, including the energy conversion to electricity and/ or heat or cooling produced shall be calculated as follows:
 - (i) For energy installations delivering only heat:

$$EC_h = \frac{E}{\eta_h}$$

(ii) For energy installations delivering only electricity:

$$EC_{el} = \frac{E}{\eta_{el}}$$

where

 $EC_{h,el}$ = Total greenhouse gas emissions from the final energy commodity.

E = Total greenhouse gas emissions of the fuel before end-conversion.

- η_{el} = The electrical efficiency, defined as the annual electricity produced divided by the annual fuel input, based on its energy content.
- η_h = The heat efficiency, defined as the annual useful heat output divided by the annual fuel input, based on its energy content.
- (iii) For the electricity or mechanical energy coming from energy installations delivering useful heat together with electricity and/or mechanical energy:

$$EC_{el} = \frac{E}{\eta_{el}} \left(\frac{C_{el} \cdot \eta_{el}}{C_{el} \cdot \eta_{el} + C_h \cdot \eta_h} \right)$$

(iv) For the useful heat coming from energy installations delivering heat together with electricity and/or mechanical energy:

$$EC_h = \frac{E}{\eta_h} \left(\frac{C_h \cdot \eta_h}{C_{el} \cdot \eta_{el} + C_h \cdot \eta_h} \right)$$

where:

 $EC_{h,el}$ = Total greenhouse gas emissions from the final energy commodity.

E = Total greenhouse gas emissions of the fuel before end-conversion.

 η_{el} = The electrical efficiency, defined as the annual electricity produced divided by the annual energy input, based on its energy content.

 η_h = The heat efficiency, defined as the annual useful heat output divided by the annual energy input, based on its energy content.

 C_{el} = Fraction of exergy in the electricity, and/or mechanical energy, set to 100 % (C_{el} = 1).

 C_h = Carnot efficiency (fraction of exergy in the useful heat).

The Carnot efficiency, Ch, for useful heat at different temperatures is defined as:

$$C_h = \frac{T_h - T_0}{T_h}$$

where:

- T_h = Temperature, measured in absolute temperature (kelvin) of the useful heat at point of delivery.
- T_0 = Temperature of surroundings, set at 273.15 kelvin (equal to 0 °C) For T_h , < 150 °C (423.15 kelvin), C_h can alternatively be defined as follows:
- C_h = Carnot efficiency in heat at 150 °C (423.15 kelvin), which is: 0.3546

For the purposes of this calculation, the following definitions shall apply:

- (i) "cogeneration" shall mean the simultaneous generation in one process of thermal energy and electricity and/or mechanical energy;
- (ii) "useful heat" shall mean heat generated to satisfy an economical justifiable demand for heat, for heating or cooling purposes;
- (iii) "economically justifiable demand" shall mean the demand that does not exceed the needs for heat or cooling and which would otherwise be satisfied at market conditions.
- 2. Greenhouse gas emissions from biomass fuels shall be expressed as follows
 - (a) greenhouse gas emissions from biomass fuels E, shall be expressed in terms of grams of CO₂ equivalent per MJ of biomass fuel, gCO_{2eq}/MJ.

(b) greenhouse gas emissions from heating or electricity, produced from biomass fuels, EC, shall be expressed in terms of grams of CO₂ equivalent per MJ of final energy commodity (heat or electricity), gCO_{2eq}/MJ.

When heating and cooling are co-generated with electricity, emissions shall be allocated between heat and electricity (as under 1(d)) irrespective if the heat is used for actual heating purposes or for cooling.¹⁷

Where the greenhouse gas emissions from the extraction or cultivation of raw materials e ec are expressed in unit g CO₂eq/dry-ton of feedstock the conversion to grams of CO₂ equivalent per MJ of fuel, gCO₂eq /MJ shall be calculated as follows;

$$\begin{split} e_{sc}fuel_{a} & \left[\frac{gCO_{2}eq}{MJ \ fuel} \right]_{sc} \\ & = \frac{e_{sc} \ feedstock_{a} \ \left[\frac{gCO_{2}eq}{t_{dry}} \right]}{LHV_{a} \left[\frac{MJ \ feedstock}{t \ dry \ feedstock} \right]} \\ & *Fuel \ feedstock \ factor_{a} * \ Allocation \ factor \ fuel_{a} \end{split}$$

Where

$$Allocation \ factor \ fuel_a = \left[\frac{\textit{Energy in fuel}}{\textit{Energy fuel} + \textit{Energy in co-products}}\right]$$

Heat or waste heat is used to generate cooling (chilled air or water) through absorption chillers. Therefore, it is appropriate to calculate only the emissions associated to the heat produced, per MJ of heat, irrespectively if the end-use of the heat is actual heating or cooling via absorption chillers.

Emissions per dry-ton feedstock shall be calculated as follows:

$$e_{sc}feedstock_{a}\left[\frac{gCO_{2}eq}{t_{dry}}\right] = \frac{e_{sc}feedstock_{a}\left[\frac{gCO_{2}eq}{t_{moist}}\right]}{(1-moisture\;content)}$$

- 3. Greenhouse gas emission savings from biomass fuels shall be calculated as follows:
 - (a) greenhouse gas emission savings from biomass fuels used as transport fuels:

$$SAVING = (E_{F(t)} - E_{B(t)})/E_{F(t)}$$

where

 $E_{B_{(4)}}$ = total emissions from the biofuel or bioliquid; and

 $E_{F(t)}$ = total emissions from the fossil fuel comparator for transport

(b) greenhouse gas emission savings from heat and cooling, and electricity being generated from biomass fuels as follows:

$$SAVING = (EC_{F(h\&c,el)} - EC_{B(h\&c,el)})/EC_{F(h\&c,el)},$$

where

 $EC_{B(h\&c,el)}$ = total emissions from the heat or electricity,

 $EC_{F(h\&c,el)}$ = total emissions from the fossil fuel comparator for useful heat or electricity.

4. The greenhouse gases taken into account for the purposes of point 1 shall be CO₂, N₂O and CH₄. For the purpose of calculating CO₂ equivalence, those gases shall be valued as follows:

CO₂: 1

N₂O: 298

CH₄: 25

5. Emissions from the extraction, harvesting or cultivation of raw materials, e_{ec}, shall include emissions from the extraction, harvesting or cultivation process itself; from the collection, drying and storage of raw materials; from waste and leakages; and from the production of chemicals or products used in extraction or cultivation. Capture of CO₂ in the cultivation of raw materials shall be excluded. Estimates of emissions from agriculture biomass cultivation may be derived from the regional averages for cultivation emissions included in the reports referred to in Article 28 (4) of this Directive [] or the information on the disaggregated default values for cultivation emissions included in this Annex, as an alternative to using actual values. In absence of relevant information in the before mentioned reports it is allowed to calculate averages based on local farming practises based for instance on data of a group of farms, as an alternative to using actual values.

Estimates of emissions from cultivation and harvesting of forestry biomass, may be derived from the use of averages for cultivation and harvesting emissions calculated for geographical areas at national level, as an alternative to using actual values.

- 6. For the purposes of the calculation referred to in point **1, sub-point** (**a**), emission savings from improved agriculture management **e**_{sca}, such as shifting to reduced or zero-tillage, improved crop/rotation, the use of cover crops, including crop management, and the use of organic soil improver (e.g. compost, manure fermentation digestate), shall be taken into account only if solid and verifiable evidence is provided that the soil carbon has increased or that it is reasonable to expect to have increased over the period in which the raw materials concerned were cultivated while taking into account the emissions where such practices lead to increased fertiliser and herbicide use¹⁸.
- 7. Annualised emissions from carbon stock changes caused by land-use change, el, shall be calculated by dividing total emissions equally over 20 years. For the calculation of those emissions the following rule shall be applied:

$$e_l = (CS_R - CS_A) \times 3,664 \times 1/20 \times 1/P - e_B,(^{19})$$

where

 e_l = annualised greenhouse gas emissions from carbon stock change due to land-use change (measured as mass of CO₂-equivalent per unit biomass fuel energy). 'Cropland' (20) and 'perennial cropland' (21) shall be regarded as one land use;

 CS_R = the carbon stock per unit area associated with the reference land use (measured as mass (tonnes) of carbon per unit area, including both soil and vegetation). The reference land use shall be the land use in January 2008 or 20 years before the raw material was obtained, whichever was the later;

8697/17 ADD 1 REV 1 AT/st 101
ANNEX VI DGE 2B EN

Measurements of soil carbon can constitute such evidence, e.g. by a first measurement in advance of the cultivation and subsequent ones at regular intervals several years apart. In such case, before the second measurement is available, increase in soil carbon would be estimated on the basis of representative experiments or soil models. From the second measurement onwards, the measurements would constitute the basis for determining the existence of an increase in soil carbon and its magnitude.

The quotient obtained by dividing the molecular weight of CO2 (44,010 g/mol) by the molecular weight of carbon (12,011 g/mol) is equal to 3,664

Cropland as defined by IPCC

Perennial crops are defined as multi-annual crops, the stem of which is usually not annually harvested such as short rotation coppice and oil palm.

 CS_A = the carbon stock per unit area associated with the actual land use (measured as mass (tonnes) of carbon per unit area, including both soil and vegetation). In cases where the carbon stock accumulates over more than one year, the value attributed to CS_A shall be the estimated stock per unit area after 20 years or when the crop reaches maturity, whichever the earlier; and

P = the productivity of the crop (measured as biomass fuel energy per unit area per year). e $_B$ = bonus of 29 gCO_{2eq}/MJ biomass fuel if biomass is obtained from restored degraded land under the conditions provided for in point 8.

- 8. The bonus of 29 gCO_{2eq} /MJ shall be attributed if evidence is provided that the land:
 - (a) was not in use for agriculture in January 2008; and
 - (b) is severely degraded land, including such land that was formerly in agricultural use. The bonus of 29 gCO_{2eq} /MJ shall apply for a period of up to 20 years from the date of conversion of the land to agricultural use, provided that a steady increase in carbon stocks as well as a sizable reduction in erosion phenomena for land falling under (b) are ensured.
- 9. 'Severely degraded land' means land that, for a significant period of time, has either been significantly salinated or presented significantly low organic matter content and has been severely eroded.

- In accordance with Annex V, Part C, point 10 of this Directive guidelines for the calculation of land carbon stocks²² adopted in relation to that Directive, drawing on the 2006 IPCC Guidelines for National Greenhouse Gas Inventories volume 4, and in accordance with the Regulation (EU) No 525/2013²³ and the Regulation (INSERT THE NO AFTER THE ADOPTION²⁴), shall serve as the basis for the calculation of land carbon stocks.
- 11. Emissions from processing, e_p , shall include emissions from the processing itself; from waste and leakages; and from the production of chemicals or products used in processing, including the carbon dioxide emissions corresponding to the carbon contents of fossil inputs, whether or not actually combusted in the process.

In accounting for the consumption of electricity not produced within the **solid or** gaseous biomass fuel production plant, the greenhouse gas emission intensity of the production and distribution of that electricity shall be assumed to be equal to the average emission intensity of the production and distribution of electricity in a defined region. By derogation from this rule, producers may use an average value for an individual electricity production plant for electricity produced by that plant, if that plant is not connected to the electricity grid.

Emissions from processing shall include emissions from drying of interim- products and materials where relevant.

Commission Decision of 10 June 2010 (2010/335/EU) on guidelines for the calculation of land carbon stocks for the purpose of Annex V to Directive 2009/28/EC, OJ L 151 17.06.2010

Regulation (EU) 525/2013 of the European Parliament and of the Council of 21 may 2013 on a mechanism for monitoring and reporting greenhouse gas emissions and for reporting other information at national and Union level relevant to climate change and repealing Decision No 280/2004/EC, OJ L 165/13, 18.06.2013

Regulation of the European Parliament and of the Council (insert the date of entry into force of this Regulation) on the inclusion of greenhouse gas emissions and removals from land use, land use change and forestry into the 2030 climate and energy framework and amending Regulation No 525/2013 of the European Parliament and the Council on a mechanism for monitoring and reporting greenhouse gas emissions and other information relevant to climate change.

- 12. Emissions from transport and distribution, e_{td} , shall include emissions from the transport of raw and semi-finished materials and from the storage and distribution of finished materials. Emissions from transport and distribution to be taken into account under point 5 shall not be covered by this point.
- 13. Emissions of CO₂ from fuel in use, e_u , shall be taken to be zero for biomass fuels. Emissions of non-CO₂ greenhouse gases (CH₄ and N₂O) from the fuel in use shall be included in the e_u factor.
- 14. Emission saving from carbon capture and geological storage, e_{ccs} , that have not already been accounted for in e_p , shall be limited to emissions avoided through the capture and storage of emitted CO₂ directly related to the extraction, transport, processing and distribution of biomass fuel if stored in compliance with Directive 2009/31/EC on the geological storage of carbon dioxide.
- 15. Emission saving from carbon capture and replacement, e_{ccr} , shall be related directly to the production of biomass fuel they are attributed to, and shall be limited to emissions avoided through the capture of CO₂ of which the carbon originates from biomass and which is used to replace fossilderived CO₂.
- 16. Where a cogeneration unit providing heat and/ or electricity to a biomass fuel production process for which emissions are being calculated produces excess electricity and/or excess useful heat, the greenhouse gas emissions shall be divided between the electricity and the useful heat according to the temperature of the heat (which reflects the usefulness (utility) of the heat). The allocation factor, called Carnot efficiency Ch, is calculated as follows for useful heat at different temperatures:

$$C_h = \frac{T_h - T_0}{T_h}$$

where

 T_h = Temperature, measured in absolute temperature (kelvin) of the useful heat at point of delivery.

 T_0 = Temperature of surroundings, set at 273.15 kelvin (equal to 0 °C)

For T_h, < 150 °C (423.15 kelvin), C_h can alternatively be defined as follows:

C_h = Carnot efficiency in heat at 150 °C (423.15 kelvin), which is: 0.3546

For the purposes of this calculation, the actual efficiencies shall be used, defined as the annual mechanical energy, electricity and heat produced respectively divided by the annual energy input.

For the purposes of this calculation, the following definitions shall apply:

- (a) "cogeneration" shall mean the simultaneous generation in one process of thermal energy and electrical and/or mechanical energy;
- (b) "useful heat" shall mean heat generated to satisfy an economical justifiable demand for heat, for heating or cooling purposes;
- (c) "economically justifiable demand" shall mean the demand that does not exceed the needs for heat or cooling and which would otherwise be satisfied at market conditions

- 17. Where a biomass fuel production process produces, in combination, the fuel for which emissions are being calculated and one or more other products ("co-products"), greenhouse gas emissions shall be divided between the fuel or its intermediate product and the co-products in proportion to their energy content (determined by lower heating value in the case of co-products other than electricity and heat). The greenhouse gas intensity of excess useful heat or excess electricity is the same as the greenhouse gas intensity of heat or electricity delivered to the biomass fuel production process and is determined from calculating the greenhouse gas intensity of all inputs and emissions, including the feedstock and CH₄ and N₂O emissions, to and from the cogeneration unit, boiler or other apparatus delivering heat or electricity to the biomass fuel production process. In case of cogeneration of electricity and heat the calculation is performed following point 16.
- 18. For the purposes of the calculations referred to in point 17, the emissions to be divided shall be $e_{ec} + e_l + e_{sca} +$ those fractions of e_p , e_{td} , e_{ccs} and e_{ccr} that take place up to and including the process step at which a co-product is produced. If any allocation to co-products has taken place at an earlier process step in the life-cycle, the fraction of those emissions assigned in the last such process step to the intermediate fuel product shall be used for this purpose instead of the total of those emissions.

In the case of biogas and biomethane, all co-products that do not fall under the scope of point 7 shall be taken into account for the purposes of that calculation. No emissions shall be allocated to wastes and residues. Co-products that have a negative energy content shall be considered to have an energy content of zero for the purpose of the calculation.

Wastes and residues, including tree tops and branches, straw, husks, cobs and nut shells, and residues from processing, including crude glycerine (glycerine that is not refined) and bagasse, shall be considered to have zero life-cycle greenhouse gas emissions up to the process of collection of those materials irrespectively of whether they are processed to interim products before being transformed into the final product.

In the case of biomass fuels produced in refineries, other than the combination of processing plants with boilers or cogeneration units providing heat and/or electricity to the processing plant, the unit of analysis for the purposes of the calculation referred to in point 17 shall be the refinery.

19. For biomass fuels used for electricity production, for the purposes of the calculation referred to in point 3, the fossil fuel comparator $EC_{F(el)}$ shall be 183 gCO2_{eq}/MJ electricity.

For biomass fuels used for useful heat, for heating and/or cooling production, for the purposes of the calculation referred to in point 3, the fossil fuel comparator $EC_{F(h)}$ shall be 80 gCO2eq/MJ heat.

For biomass fuels used for useful heat production, in which a direct physical substitution of coal can be demonstrated, for the purposes of the calculation referred to in point 3, the fossil fuel comparator $EC_{F(h)}$ shall be 124 gCO_{2eq}/MJ heat.

For biomass fuels, used as transport fuels for the purposes of the calculation referred to in point 3, the fossil fuel comparator $EC_{F(t)}$ shall be 94 gCO_{2eq}/MJ.

Case 1 refers to processes in which a Natural Gas boiler is used to provide the process heat to the pellet mill. Process electricity is purchased from the grid.

Case 2 refers to processes in which a boiler fuelled with wood chips is used to provide the process heat to the pellet mill. Process electricity is purchased from the grid.

Case 3 refers to processes in which a CHP, fuelled with wood chips, is used to provide heat and power to the pellet mill.

	Case 1	Open digestate ²	-28	3
		Close digestate ³	-88	-84
Biogas for	Case 2	Open digestate	-23	10
electricity from wet manure		Close digestate	-84	-78
	Case 3	Open digestate	-28	9
		Close digestate	-94	-89

The group of agricultural residues with higher bulk density includes materials such as corn cobs, nut shells, soybean hulls, palm kernel shells (not exhaustive list).

Open storage of digestate accounts for additional emissions of methane which change with the weather, the substrate and the digestion efficiency. In these calculations the amounts are taken to be equal to 0.05 MJCH4 / MJbiogas for manure, 0.035 MJCH4 / MJbiogas for maize and 0.01 MJCH4 / MJbiogas for biowaste.

Close storage means that the digestate resulting from the digestion process is stored in a gas tight tank and the additional biogas released during storage is considered to be recovered for production of additional electricity or biomethane.

This category includes the following categories of technologies for biogas upgrade to biomethane: Pressure Swing Adsorption (PSA), Pressure Water Scrubbing (PWS), Membranes, Cryogenic, and Organic Physical Scrubbing (OPS). It includes an emission of 0.03 MJCH4/MJbiomethane for the emission of methane in the off-gases.

This category includes the following categories of technologies for biogas upgrade to biomethane: Pressure Water Scrubbing (PWS) when water is recycled, Pressure Swing Adsorption (PSA), Chemical Scrubbing, Organic Physical Scrubbing (OPS), Membranes and Cryogenic upgrading. No methane emissions are considered for this category (the methane in the off-gas is combusted, if any).

Comments

Case 1 refers to pathways in which power and heat required in the process are supplied by the CHP engine itself.

Case 2 refers to pathways in which the electricity required in the process is taken from the grid and the process heat is supplied by the CHP engine itself. In some Member States, operators are not allowed to claim the gross production for subsidies and Case 1 is the more likely configuration.

Case 3 refers to pathways in which the electricity required in the process is taken from the grid and the process heat is supplied by a biogas boiler. This case applies to some installations in which the CHP engine is not on-site and biogas is sold (but not upgraded to biomethane).

Typical and default values – biomethane - mixtures of manure and maize: GHG emissions with shares given on a fresh mass basis

In case of biomethane used as Compressed Biomethane as a transport fuel, a value of 3.3 gCO2eq./MJ biomethane needs to be added to the typical values and a value of 4.6 gCO2eq./MJ biomethane to the Default values.

↓ 2009/28/EC

annex vi

↓ 2009/28/EC (adapted)

ANNEX VII

Accounting of energy from heat pumps

The amount of aerothermal, geothermal or hydrothermal energy captured by heat pumps to be considered energy from renewable sources for the purposes of this Directive, E_{RES} , shall be calculated in accordance with the following formula:

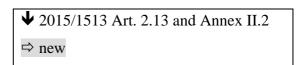

$$E_{RES} = Q_{usable} * (1 - 1/SPF)$$

where

- Q_{usable} = the estimated total usable heat delivered by heat pumps fulfilling the criteria referred to in Article 7 $\frac{5}{4}$, implemented as follows: Only heat pumps for which SPF > 1.15 * 1/η shall be taken into account,
- SPF = the estimated average seasonal performance factor for those heat pumps,
- η is the ratio between total gross production of electricity and the primary energy consumption for electricity production and shall be calculated as an EU average based on Eurostat data.

By 1 January 2013, the Commission shall establish guidelines on how Member States are to estimate the values of *Q*_{waable} and SPF for the different heat pump technologies and applications, taking into consideration differences in climatic conditions, especially very cold climates.

ANNEX VIII

PART A. PROVISIONAL ESTIMATED INDIRECT LAND-USE CHANGE EMISSIONS FROM BIOFUEL AND BIOLIQUID FEEDSTOCKS (GCO_{2EQ}/MJ) \Rightarrow $^1 \Leftarrow$

Feedstock group	Mean ⇒ ² ⇔	Interpercentile range derived from the sensitivity analysis ⇒ ³ ←
Cereals and other starch-rich crops	12	8 to 16
Sugars	13	4 to 17
Oil crops	55	33 to 66

_

The mean values reported here represent a weighted average of the individually modelled feedstock values. The magnitude of the values in the Annex is sensitive to the range of assumptions (such as treatment of co-products, yield developments, carbon stocks and displacement of other commodities) used in the economic models developed for their estimation. Although it is therefore not possible to fully characterise the uncertainty range associated with such estimates, a sensitivity analysis conducted on the results based on a random variation of key parameters, a so-called Monte Carlo analysis, was conducted.

² The mean values included here represent a weighted average of the individually modelled feedstock values.

The range included here reflects 90 % of the results using the fifth and ninety-fifth percentile values resulting from the analysis. The fifth percentile suggests a value below which 5 % of the observations were found (i.e. 5 % of total data used showed results below 8, 4, and 33 gCO2eq/MJ). The ninety-fifth percentile suggests a value below which 95 % of the observations were found (i.e. 5 % of total data used showed results above 16, 17, and 66 gCO2eq/MJ).

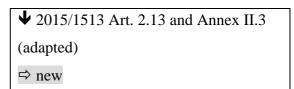

PART B. BIOFUELS AND BIOLIQUIDS FOR WHICH THE ESTIMATED INDIRECT LAND-USE CHANGE EMISSIONS ARE CONSIDERED TO BE ZERO

Biofuels and bioliquids produced from the following feedstock categories will be considered to have estimated indirect land-use change emissions of zero:

- (1) feedstocks which are not listed under part A of this Annex.
- (2) feedstocks, the production of which has led to direct land-use change, i.e. a change from one of the following IPCC land cover categories: forest land, grassland, wetlands, settlements, or other land, to cropland or perennial cropland \Rightarrow $^1 \Leftarrow$. In such a case a direct land-use change emission value (e₁) should have been calculated in accordance with point 7 of part C of Annex V.

_

Perennial crops are defined as multi-annual crops, the stem of which is usually not annually harvested such as short rotation coppice and oil palm.

ANNEX IX

Part A. Feedstocks ⇒ for the production of advanced biofuels ⇔ and fuels, the contribution of which towards the target referred to in the first subparagraph of Article 3(4) shall be considered to be twice their energy content:

- (a) Algae if cultivated on land in ponds or photobioreactors.
- (b) Biomass fraction of mixed municipal waste, but not separated household waste subject to recycling targets under point (a) of Article 11(2) of Directive 2008/98/EC.
- (c) Bio-waste as defined in Article 3(4) of Directive 2008/98/EC from private households subject to separate collection as defined in Article 3(11) of that Directive.
- (d) Biomass fraction of industrial waste not fit for use in the food or feed chain, including material from retail and wholesale and the agro-food and fish and aquaculture industry, and excluding feedstocks listed in part B of this Annex.
- (e) Straw.
- (f) Animal manure and sewage sludge.
- (g) Palm oil mill effluent and empty palm fruit bunches.
- (h) Tall oil pitch.
- (i) Crude glycerine.

(i)	Bagasse
\ I /	Dagassc

- (k) Grape marcs and wine lees.
- (1) Nut shells.
- (m) Husks.
- (n) Cobs cleaned of kernels of corn.
- (o) Biomass fraction of wastes and residues from forestry and forest-based industries, i.e. bark, branches, pre-commercial thinnings, leaves, needles, tree tops, saw dust, cutter shavings, black liquor, brown liquor, fibre sludge, lignin and tall oil.
