- **Coherence for impact:** The extent and speed by which the expected results and impacts will be reached, will depend on the scale of the R&I efforts triggered, the profile of the partners involved, the strength of their commitments, and the scope of the R&I activities funded. To be fully effective it comes out clearly that future partnerships need to operate over their whole life cycle in full coherence with their environment, including potential end users, regulators and standardisation bodies. This relates also to the alignment with relevant EU, national or regional policies and synergies with R&I programmes. This needs to be factored in as of the design stage to ensure a wide take-up and/or deployment of the solutions developed, including their interoperability.
- **Collaboration for impact:** Effectiveness could also be improved collectively through enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems. An adequate governance structure appears in particular necessary to ensure cross-fertilisation between all European Partnerships. This applies not only to initiatives where similar R&I topics are covered and/or the same stakeholders involved or targeted, but also to the interconnections needed between the ‘thematic’ and the ‘vertical’ Partnerships, as these are expected to develop methodologies and technologies for application in EU priority areas. Already at very early stages of preparing new initiatives, Strategic Research and Innovation Agendas and roadmaps need to be aligned, particularly for partnerships that develop enabling technologies that are needed in other Partnerships. The goal should be to achieve greater impacts jointly in light of common challenges.
- **Efficiency for impact:** Potential efficiency gains could also be achieved by joining up the operational functions of Joint Undertakings that do not have a strong context dependency and providing them through a common back-office³⁴. A number of

³⁴ See Annex 6 for an overview of the key functions/roles that could be provided by a common back office.

operational activities of the Joint Undertakings are of a technical or administrative nature (e.g. financial management of contracts), or procured from external service providers (e.g. IT, communication activities, recruitment services, auditing) by each Joint Undertaking separately. If better streamlined this could create a win-win situation for all partners leading to better harmonization, economies of scales, and less complexity in supervision and support by the Commission services.

2.4.2. Analysis of coherence of the overall portfolio of candidate initiatives at the thematic level

Looking at the coherence of the set of initiatives at the thematic level, the “**digital centric**” initiatives have a strong focus on supporting the digital competitiveness of the EU ecosystem. Their activities are expected to improve alignment and coordination with Member States and industry for the development of world-competitive EU strategic digital technology value chains and associated expertise. Addressing the Key Digital Technologies, the 5G and 6G connectivity needs as part of a Smart Networks and Services initiative and the underlying supercomputing capacities through a European High Performance Computing initiative present potential for synergies that can be addressed through cooperative actions (e.g. joint calls, coordinated support activities, etc.). They may as well profit from and contribute to Partnerships envisaged for Photonics, AI, data, robotics, Global competitive space system and Made in Europe, together with the EIT Digital. Synergies between these initiatives and several programmes (Digital Europe and Connecting Europe as well as cohesion programmes) are needed in areas where EU industry has to develop leadership and competitiveness in the global digital economy. They are expected to impact critical value chains including on sectors where digital is a strong enabler of transformation (health, industrial manufacturing, mobility/transport, etc.).

The **transport** sector face systemic changes linked to decarbonisation and digitalisation. Large scale R&I actions are needed to provide cleaner, safer, and economically viable services for citizens and businesses, with digitalisation and automation as enablers. Past decades have shown that developing and implementing change is difficult in transport due to its systemic nature, many stakeholders involved, long planning cycles and large investments needed. A systemic change of the air traffic network through an Integrated Air Traffic Management initiative should ensure safety and sustainability of aviation, while a Clean Aviation initiative should focus on the competitiveness of tomorrow’s clean aircrafts made in Europe. The initiative for Transforming Europe’s rail system would comprehensively address the rail sector to confirm it as a cornerstone in tomorrow’s clean and efficient door-to-door transport services, affordable for every citizen as well as the most climate-friendly mode of transport, and becoming more attractive for passengers and freight. Connected and Automated Mobility is the future of road transport, but Europe is threatened to fall behind other global regions with strong players and large harmonised markets. The initiative Safe and Automated Road Transport would bring stakeholders together, creating joint momentum in digitalising road transport and developing new user-based services. Stronger links and joint actions will be established between initiatives to enable common progress wherever possible. The Clean Hydrogen initiative would be fundamental to that regard. Synergies would also be sought with partnerships driving the digital technological developments.

To deliver a deep decarbonisation of highly emitting industrial sectors such as the steel, transport and chemical industries would require the production, distribution and storage of **hydrogen** at scale. The candidate hydrogen initiative would have a central positioning in terms of providing solutions to the challenges for sustainable mobility and energy, but also is expected to operate in synergies with other industry related initiatives. The initiative

would interact in particular with initiatives on the zero emission road and water transport, transforming Europe's railway system, clean aviation, batteries, circular industry, clean steel and built environment partnerships. There are many opportunities for collaboration for the delivery and end-use of hydrogen. However, the Clean Hydrogen initiative would be the only partnership focused on addressing hydrogen production technologies.

Metrology, the science of measurement, is an enabler across all domains of R&I. It supports the monitoring of the Emissions Trading System, smart grids and pollution, but also contributes to meeting demands for measurement techniques from emerging digital technologies and applications. More generally, emerging technologies across a wide range of fields from biotechnologies, new materials, health diagnostics or low carbon technologies are giving rise to demands requiring a world-leading EU metrology system.

The initiative for a **Circular Bio-based Europe** is intended to solve a shortage of industry investments in the development of bio-based products whose markets do not have yet certain long-term prospects. The **Innovative Health Initiative** and **EU-Africa Global Health** address the lack of investments in the development of solutions to specific health challenges. The initiative on **Innovative SMEs** supports innovation-driven SMEs in participating in international, collaborative R&I projects with other innovative firms and research-intensive partners. As a horizontal initiative it is expected to help innovative SMEs to grow and to be successfully embedded in global value chains by developing methodologies and technologies for potential application in the other partnership areas or further development by the instruments of the European Innovation Council.

The description of the interconnections between all initiatives for each Horizon Europe cluster is provided in the policy context of each impact assessment and further assessed in the coherence assessment for each option.

PART 2 - THE CANDIDATE EUROPEAN PARTNERSHIP ON TRANSFORMING EUROPE'S RAIL SYSTEM

3. INTRODUCTION: THE POLITICAL AND LEGAL CONTEXT

Transport is fundamental to Europe's economy and society. It plays a key role in fulfilling citizens' travel needs and distributing the goods which they buy and use. As a result, transport enables economic growth and job creation: in 2019, the transport industry directly employed around 11.7 million people in the EU and accounted for about 5% of Gross Domestic Product (GDP)³⁵ and 7% of European export.

Railways contribute to the Single European Transport Area (SETA) and represent a fundamental element of the EU long term sustainable development strategy policy³⁶. Rail is already a very sustainable mode of transport, with policies such as the European Green Deal addressing the need of shifting to rail from less sustainable modes such as road in order to promote more environmentally friendly modes of transport integrating the logistic value chain as well as journeys for passengers. In terms of economic size, the direct gross value added of the Europe rail sector is € 69 billion and the indirect value amounted at € 80 billion³⁷, 1.3 million persons were directly employed in the rail sector and more than one million indirectly.

Rail transport has a series of significant advantages: a very high safety level (only 15 fatalities in 2017³⁸), low land use, high energy efficiency³⁹ and much lower environmental impact than other modes⁴⁰ (being already largely electrified), and the capacity to serve and connect both dense population areas as well as dispersed European areas (e.g. rural). Rail also contributes to decongesting dense urban areas. However, its ability to leverage these advantages and meet the evolving expectations of the European citizens and businesses is hampered by high costs, national operational barriers and limited flexibility, and in some cases poor reliability. These weaknesses have been compounded by divergent national technical standards and operating procedures, and inheritance of legacy systems, limiting the opportunities for extensive capacity use, mass manufacture, standard solutions, and, in addition, hindering cross border passenger and freight flows with the overall consequence of jeopardising the long term capacity of the system to answer the European socio-economic needs.

Over the recent years, the Europe rail sector has experienced increased competition from other non-European countries, especially in Asia, who built upon European know-how to develop rail technologies through subsidised internal markets. Maintaining a high and advanced technological position is key for global competitiveness and European jobs, with innovation being driven by demand and supply.

The introduction of new operational and technological innovative solutions to rail – enabled by digital advancements, robotics and automation to vehicles, European traffic management

³⁷ <http://cer.be/topics/economic-footprint>

³⁸ https://ec.europa.eu/transport/facts-fundings/statistics/pocketbook-2019_en

³⁹ 6 times more energy efficient than road (source CER).

⁴⁰ Rail is 9x less CO2 intensive than road for freight and air travel for passengers (source CER).

system, infrastructure, asset management, and interfaces with passengers and logistic value chain – will allow rail to transform its performance over the years, breaking down barriers.

This document focuses on assessing the most effective, efficient and coherent way of implementing an initiative which would focus on joint European research and innovation activities, covering the full innovation lifecycle for impact, to transform Europe's rail system under Horizon Europe.

3.1. Emerging challenges in the field

Environmental challenges and climate change are issues that are going to shape more and more citizen's everyday life and will affect the transport system too. Transport accounts for some 25% of all GHG emissions. Extreme weather conditions (e.g. flooding, hurricanes and storms) are experienced more and more often and this is increasing the risk of disruptions, damage and failure of critical infrastructure.

Another challenge is the **congestion of infrastructure -and ageing population**. 75% of the world's population (6.1 billion people) currently lives in urban areas, doubling the numbers registered in 1975, while in the EU is estimated to increase from 72% in 2015 to 84% by 2030⁴¹. The ageing of the population affects not only the end-users but also the work force in the rail sector: a large portion of operators and infrastructure managers, in particular, have a staff population with an average age above 50, which means that they will lose large part of their staff within the next decade requiring a substantial shift of skills and competencies.

Rapid technological development, notably digitalisation, automation and robotics, reshape mobility concepts and open new opportunities. The emergence of new technologies (such as 5G, big data, the Internet of Things, automation, artificial intelligence, and blockchain) is considered a powerful driver, increasing efficiency and effectiveness of the solutions and addressing environmental/sustainability challenges delivering resilient, versatile and flexible services for both passengers and freight. However, technological changes carry a significant risk of cyber-attacks that require to consider security mechanisms in the early stages of development of new technological solutions.

Box 1 Possible impact of Covid-19 crisis

The short-term impact of the pandemic on the transport sector, in particular passenger transport, is dramatic and unprecedented on this scale. The long-term effects on transport activity will be related to the length of the pandemic and the depth of the post COVID economic shock.

Mobility patterns and hence the demand are impacted. Sector associations reported an 80-90% reduction in international passenger traffic and increase in ticket reimbursement requests. New entrant operators indicated deep financial distress and may struggle to survive. Rail freight transport was largely exempted from these measures and continues to run smoothly, albeit with much reduced demand overall (some -30%). Still, it saw demand increased on some market segments (combined transport, food products, consumer goods), linked to a shift from road transport to rail.

⁴¹ See United Nations Population Division, World Urbanisation Prospects 2018, available at: <https://population.un.org/wup/Download/>

According to first estimations⁴², the global rail freight market is expected to decline from \$97.3 billion in 2019 to \$94.9 billion in 2020 at a compound annual growth rate (CAGR) of -2.5%. The decline is mainly due to economic slowdown across countries owing to the COVID-19 outbreak and the measures to contain it. The market is then expected to recover and grow at a CAGR of 7% from 2021 and reach \$114.3 billion in 2023.

Moreover, behavioural changes taking place around the world might carry over beyond the pandemic. It is unclear yet to what extent the restrictions would impact the demand for rail services.

Taken together, these challenges have important implications for both the direction and organisation of rail-related research and innovation in the next programming period.

Stakeholder opinion

There was strong support among stakeholders responding to the Open Public Consultation for aligning the direction of R&I under Horizon Europe with key European policy objectives, in particular decarbonisation of the European economy. A substantial majority of business organisations (both large organisations and SMEs), business associations, academic and research institutions, public authorities and EU citizens considered that any future European Partnership should respond effectively to European policy goals. A majority of these groups also confirmed the importance of meeting societal needs and contributing to Sustainable Development Goals while supporting EU global competitiveness. There was particularly strong

3.2. EU relative positioning in the field

The majority of rail transport is already electric (circa 80% of passenger-km and freight tonne-km⁴³), and more generally rail is very energy efficient. A significant increase of the modal share of rail transport⁴⁴ for passengers and especially for freight would allow rail to make a very substantial contribution to the decarbonisation of the transport system (increasing electrification and fuel efficiency will further reduce emissions per passenger-km and per tonne-km). The Green Deal calls for a significant part of the freight transport currently carried by road to be shifted to rail and inland waterways. Rail freight's modal share has been stagnating over the past years. It is particularly energy efficient, but in order to attract new traffic, rail freight operators have to offer more flexible and reliable services.

The EU has already started to tackle sustainability and cost-efficiency issues but it is only through intensive exploitation of the existing infrastructure, via a substantial transformation of rail systems' concept of operations, in all its segments, that a significant increase of the modal share for passengers and especially for freight could be achieved. Thus addressing the problems preventing rail taking a higher market share is a key deliverable for transport decarbonisation.

⁴² Rail Freight Global Market Report 2020-30: Covid 19 Impact and Recovery

⁴³ https://ec.europa.eu/transport/facts-fundings/statistics/pocketbook-2019_en

⁴⁴ The modal share of rail transport (including heavy rail, tram and metro services) remained stagnant over a period of more than 10 years. However, it has to be noted that heavy freight (coal, steel etc.) in which rail was historically very strong, has greatly declined due to changes in broader industrial structure, and so the fact that overall rail freight market share has remained more or less constant demonstrates that rail *has* managed to increase its share in other sectors.

Similarly, the contribution of rail in addressing the challenges arising from increased urbanisation, including congestion and poor air quality should be higher. This would require further improving the quality of the rail services: 66% of Europeans are satisfied with the frequency of trains, and punctuality and reliability are also well received, with 59% of users satisfied⁴⁵, but further improvements in the quality of rail services would encourage people to travel more by rail. A change in the mobility behaviour is also a result of the increased awareness for sustainability among the population.

High-speed rail provides an important alternative to aviation. According to a report produced by IEA in 2019⁴⁶, high-speed rail lines can reduce aviation transport on the same routes by as much as 80%, see Figure 1.

Figure 1 - Average change in passenger activity on selected air routes after high-speed rail implementation

The integration of rail within the multimodal transport system has proceeded in the past on a piecemeal slow-pace basis, constraining improvements in connectivity.

The European Rail Supply Industry (RSI) has been highly competitive in global markets over many years⁴⁷, and its technological leadership has been strengthened considerably by various EU policy initiatives, notably the European Railway Traffic Management System (ERTMS). The European RSI is a major exporter of rail equipment, for example exporting €4.8 billion of locomotive and rolling stock products in 2017 compared with €2.3 billion exported by China and a similar value by the US.

However, the European rail supply industry’s competitive position has been increasingly challenged by suppliers based in Asia, and particularly China, over several years, not least because of their substantial investment in R&I and support provided by their respective national governments⁴⁸. More generally, a perceived imbalance in the openness of Europe’s rail market compared to that in other countries has prompted the Commission to explore

⁴⁵ European Commission (2018), Flash Eurobarometer 463: Europeans’ satisfaction with passenger rail services, available at: https://data.europa.eu/euodp/en/data/dataset/S2172__ENG

⁴⁶ <https://www.iea.org/reports/the-future-of-rail>

⁴⁷ European Commission (2019), Final report of the expert group on competitiveness of the European rail supply industry, October 2019, available at: <https://ec.europa.eu/docsroom/documents/37829>

⁴⁸ See European Commission (2019b), op. cit.

ways of stemming unfair competitive practices and of providing support to European firms struggling to access global markets⁴⁹.

Through joint Rail Research and Innovation, the RSI working with the key stakeholders of the sector – railway undertakings, infrastructure managers, scientific community, etc. - through co-creation – from exploring, conception, research, design, testing and demonstrating at large operational scale – could build upon its strengths and a portfolio of solutions – e.g. ERTMS – to maintain its leadership at global level.

A review⁵⁰ conducted in 2015⁵¹ highlighted the significantly higher intensity of R&D effort in competing sectors, notably aviation and automotive, notwithstanding their apparent similarity to rail in terms of both industry structure and the costs and risks of R&D investment. The rail industry still gets relatively small amounts of R&I investments, especially when compared to the automotive industry (40 times smaller)⁵². UNIFE has estimated the level of investment in R&I undertaken by the RSI in 2014 at around 2.7% of the industry's turnover. Moreover, the total amount of European R&I investments in the rail sector is still significantly lower when compared to the US and China⁵³.

Furthermore, the competitiveness of the RSI relies heavily on the ability to maintain know-how as well as generate and protect intellectual property rights.

The recent study on the competitiveness of the RSI, undertaken for the Commission, found that of the 187,642 patents granted worldwide between 2011 and 2017 under the International Patent Classification 'B61 – Railways', 66% were granted by the relevant Chinese authority.

Hence, Europe's role and contribution to the current research and innovation efforts has implications for the strategic development and competitiveness of the European RSI⁵⁴.

In addition, there is a key role of the railway operating community at large and for the different segments. The market opening requires a shift in the business model relation between infrastructure managers and railway operators, as well as with the supply industry. This new business model, largely unique in the world, requires to innovate railway as an integrated system of systems, ensuring that the interfaces are duly managed and benefits maximized for the European passengers and freight business.

Support for the field in the previous Framework Programmes

⁵³ European Commission (2013), Impact Assessment accompanying the document: Proposal for a Council Regulation establishing the Shift2Rail Joint Undertaking, p.13.

⁵⁴ While published research results are, by definition, available to industries around the world, suppliers of rail products and services based close to, and potentially working collaboratively with, leading research organisations in the field are likely to benefit most from the research outputs that they produce.

Box 2 Support for the field in the previous Framework Programmes – key strengths & weaknesses identified

What was/is being done with EU research and innovation funding until now

Dedicated R&I activities related to transport and rail in particular have been supported for many years through the Framework Programmes. This covers traditional (collaborative) projects but also support provided through the Shift2Rail Joint Undertaking (S2R JU) under Horizon 2020.

The S2R JU was established in 2014 to strengthen the role of rail in the European transport system through more effective sponsorship and management of the sector's R&I effort. It manages an extensive programme of R&I activity, aligned with the delivery of a series of major operational and technological innovations set out in its Master Plan and further elaborated in a detailed Multi-Annual Action Plan (MAAP). The Union financial contribution is EUR 450 million that is matched by a similar contribution from the members. Details on how the S2R JU functions are available in Annex 6.

The activity overseen by the JU represents a substantial contribution to the R&I effort of the European RSI. The relatively low intensity of R&I activity in the rail sector observed before Horizon 2020 was an important factor in building the case for establishing the JU.

The founding members of the JU, including the manufacturers Alstom, Ansaldo STS (now Hitachi), Bombardier, CAF, Siemens and Thales and the infrastructure managers Network Rail and Trafikverket, are major contributors to the work programme, as are the associate members Deutsche Bahn and SNCF.

Educational and scientific and research institutions are well represented, although participation is concentrated on a relatively limited number of organisations such as the KTH Royal Institute of Technology, Fraunhofer Gesellschaft and Deutsches Zentrum für Luft und Raumfahrt (DLR).

While the interests of rail operators are clearly represented, including by associate members, representation is distributed in favour of major national passenger operators, freight operators and operators of urban networks are less involved (although organisations such as DB Cargo, Wiener Linien, Metro de Madrid and London Underground have participated in a limited number of projects).

SMEs participate in the Open Calls; for example, 90 SMEs participated in the 2019 Call (i.e. 23% of the applicants) and 40 SMEs were beneficiaries in proposals retained for funding (i.e. 40%). Overall, the SMEs represent 30% of the entities receiving funding from S2R JU.

What has or is being achieved so far

The JU is the first of its kind. It has been successful in building participation from organisations throughout the rail industry value chain, including infrastructure managers, train operators and a wide range of organisations from the RSI as well as research and educational institutions. The profile of participation tends to reflect the allocation of available Union funding, with 40% allocated to founding members, 30% to associated members and their affiliates and 30% to open calls (in accordance with Article 17 of Annex I of the Regulation).

According to the Interim Evaluation⁵⁵ the JU had already achieved positive effects by bringing many organisations together to work towards common goals, thereby overcoming industry fragmentation and ensuring greater continuity of research objectives. The report noted widespread support for the JU across the industry, particularly in view of its role in enabling large-scale demonstration projects. Overall, it was judged to be well-placed to achieve the level of trust and partnership characteristic of other transport JUs, providing a catalyst for new ideas and new relationships. Much of the research being undertaken would not have happened if the JU had not existed, and there was wide agreement of the value of the JU when it comes to large-scale demonstration projects.

To date, the JU appears to be making a strong contribution to the development of a more competitive rail transport industry, with its Annual Activity Report for 2019 highlighting significant progress across a range of activities. The Catalogue of Solutions⁵⁶ published by the JU in 2019 illustrates what R&I investments generate as innovative solutions for market uptake. It includes 54 solutions in relation to the whole rail system and hence, covering all IPs. Each solution includes a description and specifies a targeted market, market outlook and estimated date for market uptake.

To give another example, S2R JU developed, in collaboration with industry organisations such as CAF and Wabtec Corporation, competitive automatic coupling solutions to be demonstrated on Trafikverket freight trains in September 2020. It is also seeking the support of its members in preparing a business case for the deployment of the technology, which will require funding of Euro 6 billion over six years with an indicative payback of seven years. This is expected to have a significant impact on the market for freight wagons and on the efficiency of European rail freight services.

Furthermore, the JU helped identify the areas where there is a need to better align the R&I activities with the needs of a competitive sector and confirmed the need of developing a common vision for the future technical evolution. In particular, experience has shown a need to focus in the future on system issues rather than incremental improvements to parts of the complex railway system (hence the focus should be in the future on automation and traffic management) where pan-European standardisation is vital.

What lessons have been learned?

A number of areas for improvement were identified in the interim evaluation of the Joint Undertakings under Horizon 2020⁵⁷ and will have to be better addressed in a new initiative on European rails system. These challenges include:

- With regard to directionality, a more balanced research agenda, taking account of societal and operational issues facing the rail industry and better addressing the needs of freight operators needs to be adopted.
- There is a need for greater emphasis on demonstration projects to improve market take-up of R&I outputs. This requires a move towards more R&I programmes at TRL 7-9, a significant change from the focus on TRL 1-6 under Horizon 2020.
- It is important that both the research outputs and the demonstrators are relevant to a wide range of players and the links with the operational side of both passenger and freight as

⁵⁵ Commission Staff Working Document - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, {SWD (2017) 339 final}

⁵⁶ <https://shift2rail.org/wp-content/uploads/2019/10/Catalogue-of-Solutions-Web.pdf>

⁵⁷ Commission Staff Working Document - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, {SWD (2017) 339 final}

well as with urban rail players should be strengthened. There is a need to increase the participation of a greater number of railway undertakings, and the presence of the urban sector and encouraging more Member States and especially SMEs.

- The Programme of S2R JU is structured around five Innovation Programmes (IPs)⁵⁸. This structure is not flexible enough for a strong system approach to deal with all interfaces between the subsystems and between the railway system and the “outside world and bears the risk of working in silos.
- Maximising the impacts of transport research and innovation requires supporting solutions that are closer to the market and bridging the gap to large-scale deployment of innovation. A possible successor of S2R JU should have a stronger deployment agenda.
- There has been insufficient exploitation of synergies between the S2R JU and other JUs, particularly in view of application of key technologies such as digital across the transport sector and more broadly.

It has to be noted that the S2R JU achieved autonomy in May 2016, therefore it was too early for any research results to be included in the evaluation, as no projects had then reached the stage of having concrete outputs.

3.3. EU policy context beyond 2021

At the end of 2019 the Commission presented its new priorities for the upcoming years, including the **European Green Deal**, a new growth strategy that aims to transform the EU into a fair and prosperous society, with a modern, resource-efficient and competitive economy where there are no net emissions of greenhouse gases in 2050 and where economic growth is decoupled from resource use. Priority areas include accelerating the shift to sustainable and smart mobility. Road, rail, aviation, and waterborne transport will all have to contribute to the 90% reduction in transport emissions, which is needed by 2050. As a matter of priority, a substantial part of the 75% of inland freight carried today by road should shift onto rail and inland waterways.

The **New Industrial Strategy for Europe**⁵⁹ (March 2020) underlined that sustainable and smart mobility industries, such as the rail industry, have both the responsibility and the potential to drive the digital and green transition, support Europe’s industrial competitiveness and improve connectivity. In this context, the Strategy mentions the need for promoting the technological leadership of EU mobility industries.

In Horizon Europe, the candidate partnership for Transforming Europe’s Rail System is part of the R&I activities funded under the **Pillar II Cluster Climate, Energy and Mobility** are intended to contribute to the attainment of at least three of the six main ambitions for Europe: ‘A European Green Deal’, ‘A People-centred Economy’ and ‘A Digital Europe’.

The main objectives of this cluster are to fight climate change, improve the competitiveness of the energy and transport industry as well as the quality of the services that these sectors bring to society. This is supportive of several Sustainable Development Goals (SDG) including affordable and clean energy (SDG7); industry, innovation & infrastructure

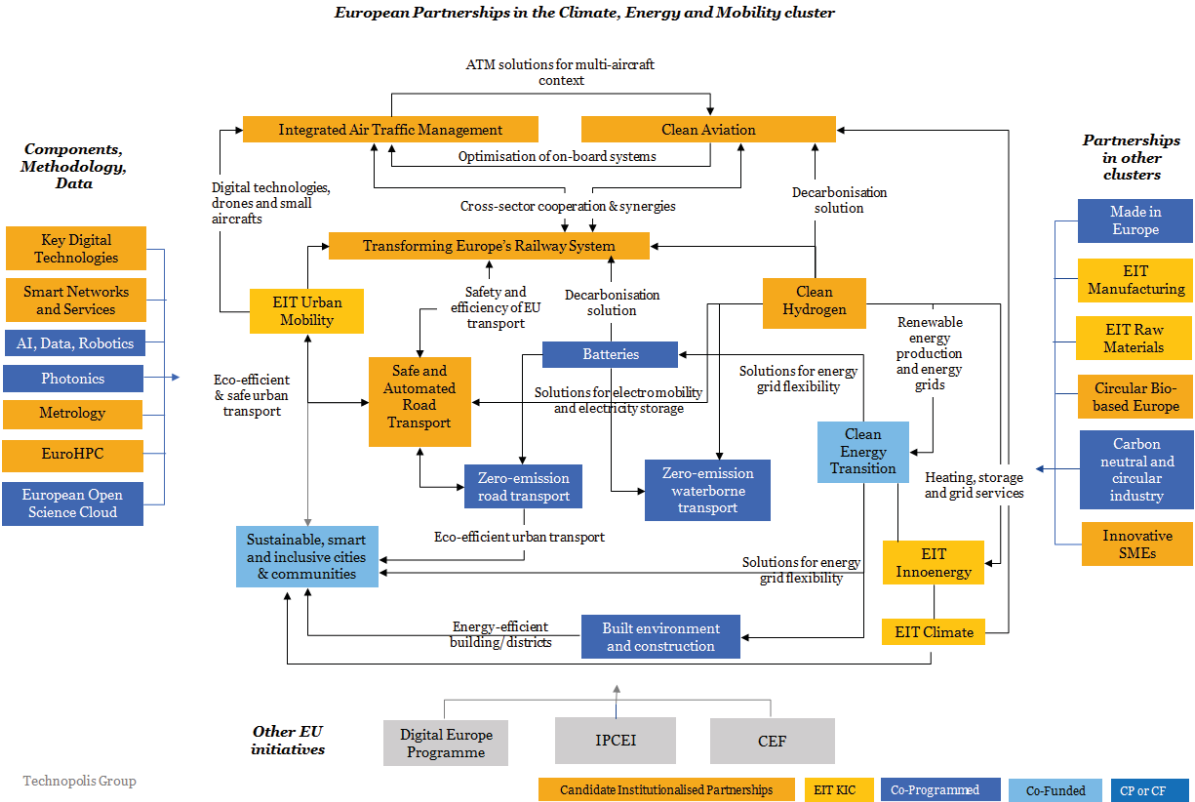

⁵⁸ The five Innovation Programmes (IP) are: Cost-efficient reliable trains, Advanced traffic management, Sustainable and Reliable Infrastructure, IT Solutions and Technologies for Rail Freight. Across all five IPs are overlaid five cross cutting themes and activities (CCAs).

⁵⁹ https://ec.europa.eu/info/strategy/priorities-2019-2024/europe-fit-digital-age/european-industrial-strategy_en

(SDG9); sustainable cities & communities (SDG11); sustainable consumption & production (SDG12); and climate action (SDG13). The candidate partnership for Transforming Europe’s Rail System also has the potential to support SDG 3 (Good Health and Well-being) -by encouraging greater use of rail services, which in turn will have a positive effect on reduction of greenhouse gas emissions, particulate pollution and noise-, SDG 8 (Decent Work and Economic Growth) and SDG 9 (Industry, Innovation and Infrastructure), by enhancing the competitiveness of rail and especially freight (thereby reducing the volume of freight traffic moving by road) and by addressing many of the challenges such as the increased urbanisation of Europe’s population.

A detailed analysis of synergies for the envisaged and candidate Partnerships that are related to this cluster is shown in Figure 2.

Figure 2 - Interconnections between the envisaged partnerships in the Climate, Energy and Mobility cluster

In terms of the **policy goals for the sector**, rail is at a point where substantial transformation is needed. Over the past 25 years, the Commission - and more recently with the European Union Agency for Railways (ERA)-, has developed a single technical framework for rail, with the objective of gradually replacing divergent legacy national approaches developed over the previous 150 years.

The technical pillar of the **4th Railway Package** adopted in 2016 but only in force in all Member States from November 2020 is expected to boost the competitiveness of the railway sector by significantly reducing costs and administrative burden for railway undertakings wishing to operate across Europe, starting with ERA issuing vehicle authorizations for

placing on the market and safety certificates for railway undertakings, valid throughout the EU.

This has been accompanied by progressive market liberalisation. The market pillar of the 4th Railway Package adopted in 2016 completes the process of gradual market opening. Competition in rail passenger service markets will encourage railway operators to become more responsive to customer needs, improve the quality of their services and their cost-effectiveness.

Despite the support provided by the current EU legislation to the harmonisation and interoperability of the EU rail market, the large majority of national legacy systems is still far away from integration into the European system⁶⁰. Full realisation of the Single European Rail Area⁶¹ will however require further time due to the very long asset life of rail equipment. For instance, in 2018 there were still some 30 different signalling systems in place which were not interoperable.⁶²

There is now a great opportunity to build the future railway on a common system – which is vital for harnessing the huge potential for digitalisation and automation to reduce rail's costs, increase capacity, and enhance its flexibility and reliability. In the absence of a major system transformation during the next decade to set the basis for a system wide deployment of new technologies and operational solutions, much of the rail potential would not be realised, and undertakings would be lumbered with stranded costs, without a shared European concept of operations and joint effort to deploy it in the market.

Stakeholder opinion

There was strong support among stakeholders responding to the Open Public Consultation for aligning the direction of R&I under Horizon Europe with key European policy objectives, in particular decarbonisation of the European economy. A substantial majority of business organisations (both large organisations and SMEs), business associations, academic and research institutions, public authorities and EU citizens considered that any future European Partnership should respond effectively to European policy goals. A majority of these groups also confirmed the importance of meeting societal needs and contributing to Sustainable Development Goals while supporting EU global competitiveness. There was particularly strong

⁶⁰ [Study on the competitiveness of the Rail Supply Industry – Final Report \(2019\)](#)

⁶¹ Established by Directive 2012/34/EU.

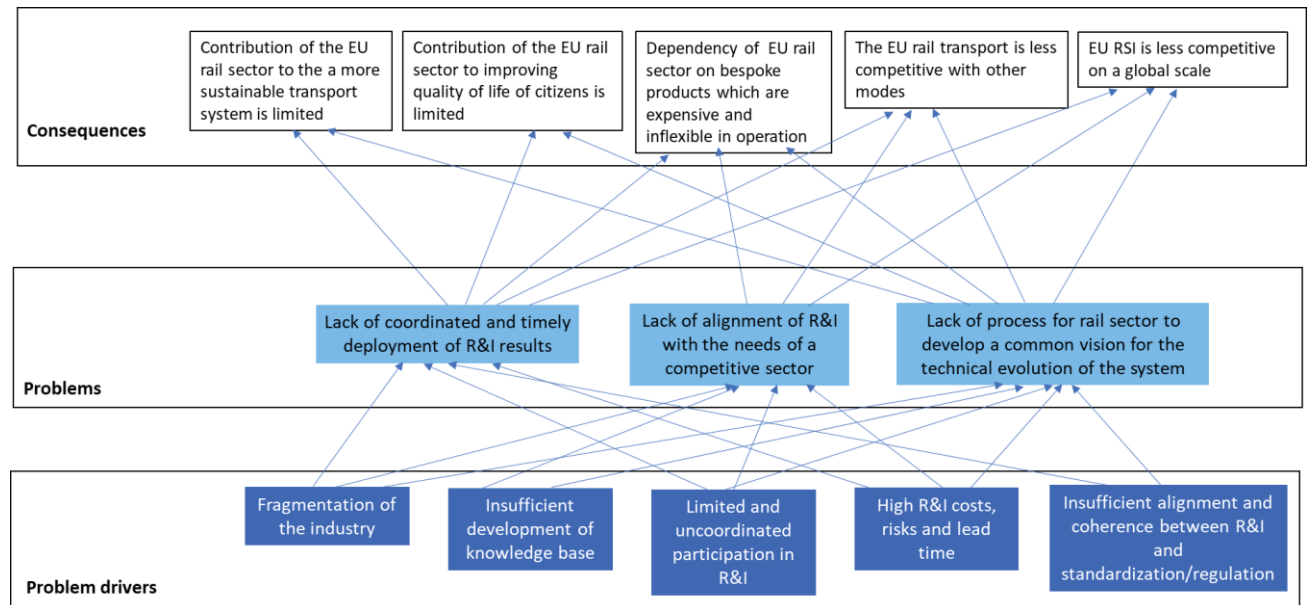

⁶² [ERTMS – A guide for stakeholders \(2020\)](#)

4. PROBLEM DEFINITION

4.1. What is/are the problems?

Given the scale of the challenges ahead for a transition to sustainable mobility, the current scientific, technological and economic positioning of Europe in the field, and the overarching EU policy context, a set of problems have been identified where EU research and innovation in the field of rails systems would have a specific role to play (see Figure 3).

Figure 3 - Problem tree behind an initiative for European research and innovation on Transforming Europe's Rail System

2.1.1 Lack of coordinated and timely deployment of R&I results both between the RUs and IMs and across the network

The current low status of deployment of innovative solutions is explained mainly by the reluctance of many IMs and RUs to invest in the necessary equipment without the assurance that there will be sufficient infrastructure to exploit the investment (where done by an RU) or trains adapted to fully exploit the infrastructure (where the IM invests) – a classic chicken and egg problem. In the absence of an adequate framework, the stakeholders considering the business case do not have confidence in the return for investment.

Previous framework programmes showed that in the absence of a strong coordinated approach at EU level, the market uptake and impact of rail R&I projects is low and slow, and neither technological nor policy-relevant outputs would be as prevalent. For projects selected individually through traditional calls for proposals the consortia are set up ad-hoc according to the specific needs of the project and dismantle afterwards without creating long term value. This hinders the continuous collaborations of partners beyond single projects, resulting in lack of trust, lack of willingness to share information – two essential factors in projects developing outputs with direct commercial value – and strategic decisions on solutions based on the monies invested in the projects instead a shared vision.

2.1.2 Rail research and innovation activities not aligned with the needs of a competitive rail sector

The lack of competitiveness of rail against other modes of transport reflects both the persistence of inefficiency, contributing to relatively high costs and/or excessive calls on public funding, and a lack of innovation.

The impact assessment accompanying the proposal to establish the S2R JU noted that R&I efforts under previous Framework Programmes had not been sufficiently targeted towards the completion of the Single European Rail Area (SERA), notwithstanding that the creation of a large internal market for rail products might have been expected to increase the competitiveness of European rail services. The recent report of the expert group on the competitiveness of Europe's RSI⁶³ noted that the industry faces several major challenges such as embracing new technologies on which both its position in global markets and the R&I activities conducted in a fragmented manner would have a little impact on meeting the needs of the sector as they would unlikely result in the level and scope of R&I activity required to materially improve the competitive position of the rail transport industry.

2.1.3 Lack of process for rail sector to develop a common vision for the technical evolution of the system

The EU rail system was historically characterised by segmentation into national networks with specific technical standards requiring bespoke rolling stock and infrastructure equipment, often supplied by preferred national manufacturers. This resulted in high costs, difficulties in providing international services and a general lack of flexibility. Even where new technologies were developed, these were often applied differently in different Member States, preventing interoperability⁶⁴. Even when a European approach (ERTMS) was developed, customisation to fit existing railway operations was allowed, again limiting the intended interoperability – a problem we are still dealing with.

Successful innovation in the rail sector must deal with these issues and also address the fact that for many developments there will only be a strong business case where wide scale network deployment in a truly interoperable manner can be ensured within a reasonable time scale.

Misalignment of incentives between infrastructure managers and railway undertakings must also be addressed. Finally, in the absence of rapid cross industry agreement on the preferred approach to new technology (including standardisation and/or inclusion of innovations in the EU Technical Standard for Interoperability Regulations) is vital to avoid that divergent solutions are adopted at national level, breaking interoperability and preventing the cost advantages delivered by common EU product specifications. These issues must be addressed with an inclusive governance system at the R&I stage to ensure broad industry acceptance of the finished technology.

⁶³ See European Commission (2019a) Report of the expert group on the RSI's competitiveness

⁶⁴ The classic example is modern train protection systems, where different automated systems were developed in the 1980s and 90s, meaning that trains needing to run in several Member States must have up to 11 different systems – adding hugely to cost and certification difficulty.

Stakeholder opinion

A substantial majority of business organisations, business associations, academic and research institutions, public authorities and EU citizens responding to the Open Public Consultation considered that the need to strengthen the role of rail in the transport system through R&I was very relevant, and support for improving the competitiveness and attractiveness of rail services was also strong among all these groups. Stakeholders also identified the importance of aligning R&I under Horizon Europe with EU societal objectives, in particular climate-related objectives. At the same time, there was strong support for common action to advance key technologies and radically transform rail, particularly from larger business organisations and public authorities.

4.2. What are the problem drivers?

4.2.1. Fragmentation

Today's fragmentation is the legacy of a patchwork of national rail systems slowly growing together:

- Infrastructure – which is and is likely to remain a national, state-owned, monopoly (with limited exceptions such as a few Public-Private-Partnerships). The need for compatibility between infrastructure and rolling stock imposes design constraints on the latter, though these are being progressively eliminated through full application of the Commission's "Technical Standards for Interoperability" (TSI) Regulations.
- Historically close links between national railways and local manufacturers, limiting incentives to develop truly pan-European products.
- Liberalisation is recent and open access for "commercial" services is small compared to services under Public Service Obligations (PSO) which represent about two thirds of the total market for passenger transport. In addition, barriers to entry are high as there is the need for example for bespoke rolling stock and to create economies of scale.
- Limited role of the cross-border traffic as 95% of it is national. Freight is very different – after 20 years of EU liberalisation the sector has evolved, with operators operating across the EU; services between Member States represent 60% of freight tonne km.
- Long life of railway assets: 40-50 years for rolling stock, while for infrastructure (including for some signalling components) is much longer.

The high level of product customisation and lack of European standardisation not only prevented the creation of single European railway market, it also resulted in increased production costs and low operational margins. The creation of the Single European Rail Area has addressed these issues by creating a single technical basis – the Technical Specifications for Interoperability (TSI) – for the system. However, it will take many years for the system to fully comply with the TSIs and in the meantime new equipment has to address interface with the legacy systems. For example, the need to manufacture rolling stock to meet specific national track and loading gauge, signalling and other standards inevitably reduces the number of trains that can be produced to a given specification and

increases the unit cost of production⁶⁵. This means that underlying R&I activities need to be properly coordinated and synchronised to ensure the interoperability of solutions.

Furthermore, the problem of fragmentation is compounded by the technical complexity of rail systems, with the risk, that, in the absence of a coordinated approach for R&I at EU level, research projects would mostly be focused on just one component of the rail system, rather than on improving the system as a whole. Given the strength of large Original Equipment Manufacturers (OEMs), there is also a limited focus on the development of a system vision or standardised interfaces between components which would allow greater scope for competition between component manufacturers and updating of such components to reflect innovation. This is being addressed in particular in the S2R JU's IPX work stream.

In addition, prior to S2R JU, there was also fragmentation along the innovation life cycle, with research projects focusing on pre-competitive innovation at low TRLs, which frequently came to an end without any plan for follow-up activity leading to market uptake. It was thus difficult to develop ambitious, large-scale and long-term innovation programmes capable of proposing breakthrough solutions that have a real impact on the whole system and that can be deployed EU wide.

Stakeholder opinion

A majority of business organisations (including SMEs), business associations, academic and research institutions, public authorities and EU citizens responding to the Open Public Consultation considered the various aspects of fragmentation discussed above to be relevant or very relevant. They also confirmed the lack of a coordinated approach to programming and funding and the need to bring together the research community, the RSI, train operators and infrastructure managers. A majority of all these groups similarly considered the market take-up of innovations to be slow, either because of deployment issues or as a result of the regulatory framework.

Several of the stakeholders participating in the interviews similarly stressed the difficulties in overcoming the fragmentation of the European rail system, particularly in view of the perceived slow progress in deploying ERTMS and delivering full interoperability. They also highlighted the long-life cycle of railway assets and the costs and risks of R&I investment as major constraints on the speed of innovation. There was a strong consensus that, in the absence of policy intervention, it would not be possible to achieve the long-term strategy and level of stakeholder participation and coordination needed to translate R&I results into higher quality, more efficient rail services. In addition, some stakeholders expressed the view that Horizon Europe represented an important opportunity to substantially improve the competitiveness of rail freight.

The business organisations providing feedback on the inception impact report also confirmed the importance of some of the problem drivers identified above, in particular the sector fragmentation. These and other stakeholders, including EU citizens, also emphasised the importance of ensuring that investment in R&I activity made a difference to the rail industry and its customers through more extensive and rapid take-up of innovation.

⁶⁵ Firm evidence of the extent of economies of scale in rolling stock manufacture is limited. However, analysis of rolling stock production in Australia by Deloitte Access Economics indicates that a quadrupling of the size of an order from, say, 40 to 160 vehicles can result in a reduction in vehicle unit cost of around 50%. See Deloitte Access Economics (2013), Opportunities for greater passenger rolling stock procurement efficiency, September 2013, available at:

<https://www2.deloitte.com/content/dam/Deloitte/au/Documents/Economics/deloitte-au-economics-passenger-rolling-stock-procurement-efficiency-opportunities-270913.pdf>

4.2.2. *Uncoordinated and limited participation in R&I*

Complex technical interactions between subsystems (infrastructure, rolling stock and signalling) and non-coordinated contribution of the railway actors (equipment manufacturers, railway undertakings and infrastructure managers, research community) limit the potential of improving one specific part of the system or the potential of proposing breakthrough solutions that have an impact on the whole system.

Before Horizon 2020, traditional calls for proposals led to formation of ad-hoc consortia and one shot demonstration projects, without all relevant market players with a commitment of implementation. Moreover, consortia frequently failed to include passenger and freight operators, notwithstanding the need to ensure that R&I activity took account of market needs.

The past set-up of EU rail R&I had limited direct leverage of EU funding. The average share of private sector funding for the FP7-Transport was only 34%, and only three projects obtained more than a 40% contribution from private sector participants. In addition, only 28% of rail projects funded under FP7-Transport were coordinated by private companies, while 43% were coordinated by university and other research organisations. This resulted in greater emphasis on projects targeting relatively low TRLs (pre-competitive research at TRL 1-3) rather than development and demonstration projects (TRL 4-7).

S2R JU shows the added value of a better representation of the whole value chain, creating continuous collaboration of partners beyond single projects, resulting in growing confidence among partners and, in many cases, greater market uptake. It runs a R&I Programme of a value of EUR 920 million, which is delivered by the European rail industry at large that contributes with own financial resources, resulting in a net contribution of EUR 470 million. The Union contribution is EUR 450 million. The leverage based on direct costs is 1 Euro funding creating 3 EUR of R&I activities.⁶⁶

The results of the consultation activities undertaken as part of this impact assessment confirm the importance of more active participation from a range of stakeholders, bringing different capabilities and a balance of perspectives. While each group has a key contribution to make, they face different incentives and constraints; therefore, operating in isolation, in the absence of a European coordination mechanism, they may be unwilling or unable to contribute in ways that maximise the efficiency and effectiveness of available R&I resources.

4.2.3. *High R&I costs, risks and lead times*

Generic innovation risks are in the rail sector intensified by the need for synchronicity between innovations. Long and diverging product lifecycles and lack of modularity, inhibiting the rapid deployment of new rail technologies; unequal distribution of innovation benefits between stakeholders, reducing incentives to invest in new technologies; lack of synergies and common standards with other industrial sectors, especially in emerging technologies.

In addition, unequal distribution of the benefits of innovation can undermine incentives to invest. Moreover, both infrastructure managers and rail operators become familiar with

⁶⁶ The current S2R JU Members funding rate is 44.44% of their overall total project costs for the indirect action they perform, corresponding to around 33% of the direct costs plus the 25% flat rate for the indirect costs.

application of technologies they have been using for many years such as electric interlocking technology, which is considered reliable and safe, and are therefore reluctant to explore the full potential of digital technology, with its own safety risks. While the prevalence of such an industry mind-set cannot be demonstrated unequivocally, to the extent that it exists it may act to further lower the industry's willingness to invest in R&I.

Furthermore, the interdependency of the different rail sub-systems means that a specific innovation (e.g. Automated Train Operation, signalling) needs to be accompanied by timely innovation in infrastructure or business models, for it to have an impact on the whole system. A Synchronicity between innovations is crucial; an innovation in one sub-system could have negative impacts on other sub-systems if not coordinated properly.

The S2R JU started delivering results breaking down the resistance to change of the rail sector and the rigidity and detachment of the rail-prone standardised/regulatory framework; but major work shall integrate the value chain of innovation to achieve the rapid deployment of innovations.

4.2.4. *Insufficient development of the knowledge base*

Historically, Europe has made a strong contribution to rail-related research, with universities and research-based institutions generating substantial numbers of publications each year. Between 2010 and 2018 China published substantially more research results than any other country, including all the main countries in which Europe's RSI is based. Moreover, while collectively the European Member States account for more publications than China and the US together, the magnitude of research effort in both these countries is sufficient to suggest that the sustainability of Europe's lead in rail research is at risk.

Before Horizon 2020, traditional calls for proposals led to formation of ad-hoc consortia with dissemination and exploitation of results on a project basis, with no links between projects and continuity. Therefore, a significant part of knowledge generated by stand-alone European R&I projects under and before FP7 never found its way to the market. Since rail-related research undertaken today provides the basis for development and innovation in the rail industry in the future, Europe's contribution to the current research effort has implications for the further development and competitiveness of the European RSI⁶⁷. In particular, the number of registered industrial designs and patents generated by the RSI is partly a function of the level of more fundamental research undertaken in the past to which suppliers have had access, either through formal collaboration with research-based organisations or because of a significant in-house research capability. The extent to which the industry can maintain intellectual property of this kind is an important determinant of its technological lead, and hence its competitiveness, in global markets.

4.2.5. *Insufficient alignment and coherence between R&I and standardisation/regulation*

With the TSIs, a strong common technical basis for key rail components has been created at EU level. However there are still significant national divergences as regards operating procedures, safety rules, and components not directly impacting interoperability. If these are not addressed and standardised in parallel with R&I development via a coordinated

⁶⁷ While published research results are, by definition, available to industries around the world, suppliers of rail products and services based close to, and potentially working collaboratively with, leading research organisations in the field are likely to benefit most from the research outputs that they produce.

approach at EU level, they will result in the continued customisation of products to national requirements, again creating complexity, cost and generally discouraging rapid innovation (see above the ERTMS example). Standardisation of rail system applications would not be approached in a coherent manner, and would not lead to new solutions that are interoperable by design and – at the same time – accelerating the market-uptake of such solutions.

Overcoming these issues is particularly important given the potential – and need – to develop and deploy new and European standardised solutions for automatic train operation, signalling, traffic management and freight operations.

A common Reference Functional System Architecture that capitalizes on the work of S2R JU can exploit standardisation opportunities. This European integration through a common understanding of the global performance of the mainline rail system and common application of operations across EU is the necessary step to ensure the achievement of SERA. To continue to build on this approach it is not sufficient to standardise once research results and products emerge. The basic system framework must be defined, through a process involving both manufacturers and operators in parallel with the commissioning of R&I work so that the results can be melded into a coherent whole.

Stakeholder opinion

Widespread recognition of the importance of these problem drivers was reflected in the responses to the Open Public Consultation. A majority of business organisations (including SMEs), business associations, academic and research institutions, public authorities and EU citizens considered the various aspects of fragmentation discussed above to be relevant or very relevant. They also confirmed the lack of a coordinated approach to programming and funding and the need to bring together the research community, the RSI, train operators and infrastructure managers. A majority of all these groups similarly considered the market uptake of innovations to be slow, either because of deployment issues or as a result of the regulatory framework.

4.3. How will the problems evolve?

There are indications⁶⁸ that the market uptake of innovative solutions has been substantially higher since the S2R JU was established and it would fall in case of no action. But in the absence of coordinated action at European level, the needs of the sector will not be met in full and the transformation of the system will not be achieved, as isolated investments in R&I done by RUs, IMs or manufacturers alone cannot ensure that. The problems that impacted the sector before the establishment of S2R JU would return.

In the absence of coordinated and higher level investment in R&I, potentially comparable with the levels achieved in the other sectors, the outputs of R&I projects would be limited as well as their market potential. Necessary improvements in the reliability, cost efficiency and capacity of the European rail network would not materialise, hindering the ability of the sector to deliver better and more cost-effective services, hence becoming more competitive and achieving the increase in modal share vital for delivering the Green Deal objectives. Especially for freight, a sector that, as mentioned above, has over the past 10 years seen a

⁶⁸ Foster Rail (on behalf of ERRAC) (2016), Evaluation of finalised projects with clear understanding of the market uptake mechanism, May 2016

stable modal share, in the absence of action at EU level, research on the communication systems, enhancing the interoperability of IT systems, and ensuring that there is enough capacity in all the routes would most probably not be done. This research would be needed to help rail freight to cope with the challenges faced, such as lower priority than for passenger services, underinvestment in infrastructure and agility and technological innovation in road transport.

If outputs already achieved under Horizon 2020 are taken up across the system, then improvements in life cycle costs could be expected by 2030. Synergies between Horizon Europe and Connecting Europe Facility (CEF) will ensure that the latter supports large scale roll-out and deployment of innovative technologies and solutions also in rail⁶⁹. They will therefore need to be combined with the market uptake assumptions to generate an estimate of actual efficiency gains. Some additional efficiency improvements are likely to be generated through additional R&I activity and investment at the national level, but these are difficult to quantify.

Stakeholder opinion

Stakeholders participating in the interviews tended to support the view that the lack of progress in addressing issues such as fragmentation and inadequate coordination of R&I activity observed before Horizon 2020 would be likely to reemerge in the absence of significant further policy intervention during Horizon Europe. Similarly, stakeholders providing feedback on the inception impact assessment tended to suggest that the problems identified in the document would be likely to persist in the absence of policy intervention.

⁶⁹ In June 2018, the European Commission, as part of proposals for the next long-term budget (2021-2027), proposed adapting the CEF programme to support investment in Europe's transport, energy and digital infrastructure networks. A provisional agreement was reached by co-legislators in March 2019.

5. WHY SHOULD THE EU ACT?

5.1. Subsidiarity: Necessity of EU action

In the absence of a rapid cross industry agreement on the preferred approach to new technology (including standardisation and/or inclusion of innovations in the TSIs it is essential to avoid that divergent solutions are adopted at national level, breaking interoperability and preventing the cost advantages delivered by common EU product specifications. An inclusive governance system at the R&I stage is required to ensure the broad industry acceptance of the developed technologies.

R&I funded at the national or organisational level, while potentially contributing to the broader development of the European rail system, is unlikely to enable the rail industry to meet European transport and broader policy objectives, advance the completion of SERA by delivering on an integrated and sustainable rail system, and lead to better and more cost effective services for passengers and businesses, as well as to an increased modal share of rail. The overall result would be a rail system whose performance will be stretched, jeopardising years of investments and action and unable to meet expectations stated in the Green Deal. There can be no Green Deal in terms of Decarbonising transport goes hand in hand with railway taking on more traffic, and for this performance and capacity have to increase more than incrementally.

Similarly, without EU action, the European Rail Supply Industry is unlikely to be able to compete in international rail product markets against suppliers based in China and other third countries actively building their indigenous rail sector capability, including through major R&I programmes.

Stakeholder opinion

Among stakeholders responding to the Open Public Consultation there was widespread recognition of the problem of fragmentation and lack of effective coordination of R&I activity underpinning the case for intervention at the European level. Stakeholders participating in the interviews and providing feedback on the inception impact assessment were also generally fully supportive of EU action to address these and other aspects of the problem.

5.2. Subsidiarity: Added value of EU action

A European integrated and complex network like rail needs a European answer: only through jointly performed rail research and innovation at Union level it will be possible to break national silos, converge on operational concepts, introduce digital technologies that will integrate local systems, create a common baseline on which to build new solutions and integrate with other modes of transport, commingle the resources to move away from 150 years old concepts and deliver an ambitious rejuvenation of rail. This should benefit from a joint effort led by Union policy to enable collaboration among actors from across Europe and along the value chain to define an integrated programme mirroring the needs of a complex system designed to address market needs, and enable a fast and targeted delivery on the objectives.

R&I at Union level would bring together the know-how of the sector reducing the overall costs in two important ways. First, it would allow pooling of resources available for R&I, thereby reducing the potential for competing and conflicting projects focusing on the needs of national networks (and tending to reinforce the geographical fragmentation of the sector). Second, it would encourage the RSI to develop products and systems that further enable the development of a fully integrated European rail system, thereby advancing the creation of a single European market for equipment and allowing them to exploit economies of scale in production more effectively.

Another aspect to be considered is that the rail sector in the different Member States, and especially SMS in South-Eastern Europe, have very different needs and are mostly concerned about meeting their basic connectivity needs (upgrading infrastructure) and focus less on R&I than the other Member States. It is important to understand these differences and apply different measures to bring EU rail systems to the same level, some of which would not be within the scope of the proposed initiative (e.g. funding and financing from EIB, CEF, ESIF); all Member States should participate in demonstrations of innovative solutions developed under this initiative.

6. OBJECTIVES: WHAT IS TO BE ACHIEVED?

6.1. General objectives of the initiative

Based on the identified problems, the following general objectives have been defined:

- The first general objective is that rail-related R&I activity under Horizon Europe should enhance rail's contribution to societal development in Europe through:
 - Support the delivery of the European Green Deal, partly by further reducing the emissions generated by the rail transport industry itself but more importantly by improving the attractiveness of rail services relative to less environmentally friendly modes (such as road and aviation) and thus enhancing air quality;
 - Supporting rail's contribution to improving the quality of life, in particular with a view to increasing connectivity, within and between Member States, by offering efficient, attractive and affordable transport services.
- The second general objective is to advance the completion of the Single European Railway Area by delivering on an integrated rail system. This would be based on a vision shared by the sector towards improved operational reliability, robustness and

efficiency, and secure the sustainability of business models for the European passengers and the freight logistic value chain. It would create a larger market for rail products and reduce costs.

- The third general objective is modernising rail freight so that it increases capability and capacity. Rail freight needs to become digital, for increased efficiency and reliability, and to be fully integrated in the logistic value chain.
- The fourth general objective is to ensure that rail-related R&I activity is better aligned with rail market needs through a user-centric approach. This will mean designing a R&I programme that delivers outputs addressing specific issues identified by rail operators, infrastructure managers and other stakeholders through a whole integrated system of systems approach, thereby delivering better performance in terms of efficiency of rail services and increasing their attractiveness to passengers and freight customers.

These objectives are fully in line with several of the SDGs⁷⁰ supported by the Climate, Energy and Mobility Cluster, including SDG 3 (Good Health and Well-being), SDG 8 (Decent Work and Economic Growth), SDG 9 (Industry, Innovation and Infrastructure), SDG 11 (Sustainable Cities and Communities) and SDG 13 (Climate Action).

6.2. Specific objectives

In order to achieve the general objectives, five specific objectives are defined. These specific objectives respond to each of the problem drivers discussed in Section 2.2. The list of specific objectives is the following:

- Eliminate barriers to interoperability and provide solutions for full integration, covering traffic management, vehicles, infrastructure and services, in order to deliver a high capacity integrated European railway network. By exploiting the huge potential for digitalisation and automation, innovative solutions will be developed to reduce rail's costs, increase capacity, and enhance its flexibility and reliability.

The above should be based upon a solid Reference Functional System Architecture⁷¹ shared by the sector, which main part is currently under development within the S2R JU together with the sector, and in coordination with the European Union Agency for Railways (ERA).

- Increase R&I activities related to rail freight and intermodal transport services, to deliver a competitive green rail freight fully integrated into the logistic value chain. Automation and digitalisation of freight train is the core, but also its operations, yards and intermodal terminals based on real time data are areas which require further R&I.
- Deliver a sustainable and resilient transport system: by developing zero-emission, silent railway system and resilient infrastructure, applying circular economy to the rail sector, and complementarity with the overall transport system.

Establish an ecosystem that facilitates interaction between stakeholders and makes cooperation within and across value chains more efficient. This will ensure that that

⁷⁰ European Commission International Cooperation and Development (2019), The Sustainable Development Goals – available at https://ec.europa.eu/europeaid/policies/sustainable-development-goals_en

⁷¹ A shared and guiding Reference Functional System Architecture includes all structural rail subsystems and their functionalities (i.e. control command and signalling, rolling stock, energy, infrastructure, etc.) and identifies the necessary interfaces and interdependencies to ensure the System maximize its performance.

research is translated into market focused innovation through demonstration and deployment.

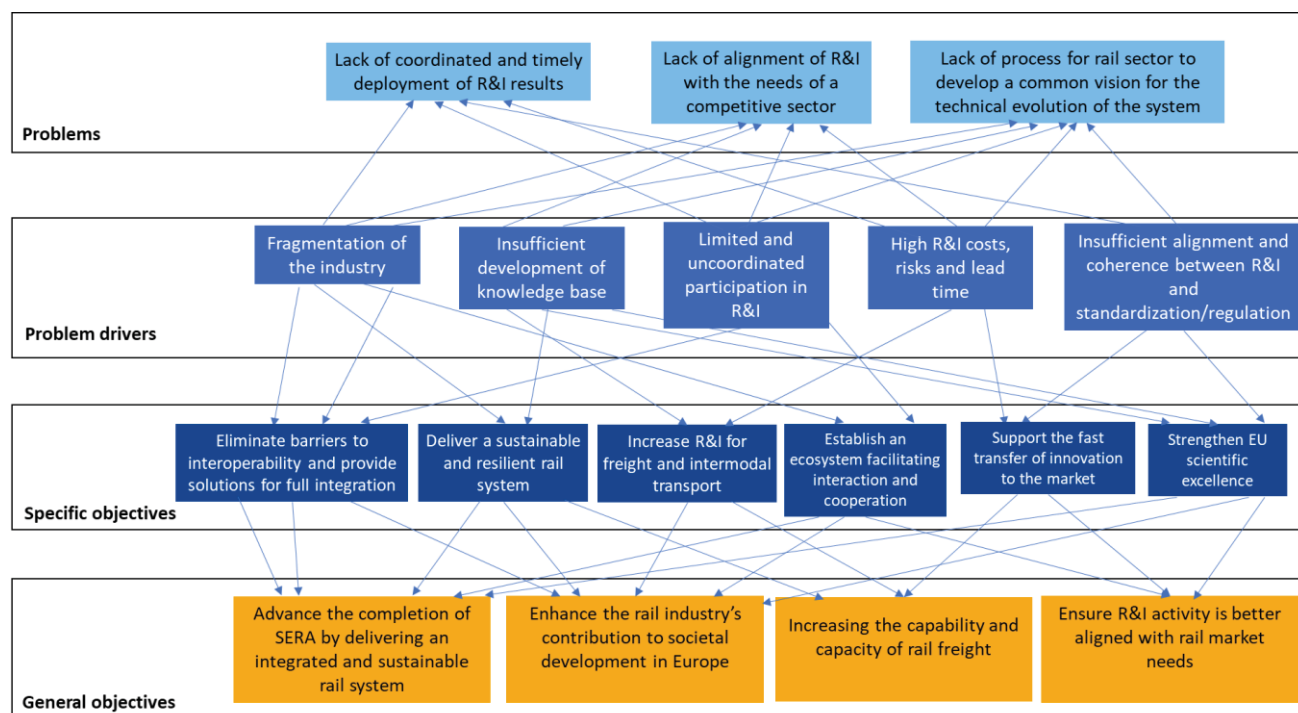

The administration and procedures for participation in the initiative would be simplified to make it accessible and attractive to new organisations. The target is to streamline administrative practices to sensibly reduce the complexity, eliminating any double EU and national intervention at all level of the operations (proposals, projects, audits).

- Launch large-scale projects supporting the fast transfer of innovation to the market. This specific objective would support large scale projects, such as demonstrations that bring together technology suppliers and users. These actions mobilise a high volume of resources and require the combination of public (European and national) and private resources under a common scheme. Large-scale projects bring specific value to the implementation of a long-term strategic planning and, by combining resources, help reducing the risks of R&I investment for organisations within the RSI and the broader rail transport sector seeking to develop and deploy new products and services. Exploiting standardisation and modularity opportunities, and facilitating the interfaces with other modes and systems would open the door to new business opportunities and contributing maintaining the leadership of the European supply industry.
- Strengthen EU scientific excellence and exploit the innovative potential of SMEs and start-ups. This would ensure achieving an advanced scientific knowledge base that could guide the development of required policy measures and technologies essential to catalyse the transition to a climate-neutral emissions economy and society. To stimulate the participation of SMEs and start-ups, efforts to simplify the administrative requirements linked to participation – with respect to those of the current partnership - will be important.

6.3. Intervention logic of the initiative

The relationship between the general and specific objectives of the potential initiative on Transforming Europe's rail system is shown in Figure 4.

Figure 4 - Intervention logic for the initiative for Transforming Europe's Rail System

How would success look like?

Should the initiative deliver on its specific objectives, it is expected that it would translate in practice into the following impacts:

Scientific impacts

- A strengthened pipeline of potential innovation available to the rail sector
- Deliver scientific results breaking down the current operating limitations
- Development of the knowledge base
- A new generation of “rail” engineers and scientists coming from different fields
- Ideas that would challenge current systems and a new thinking

Future rail research and innovation activities delivered through the partnership would contribute to scientific knowledge connecting the European research and scientific rail community with others and through the publication of results. Given the participation of a wide range of stakeholders with complementary skills and capabilities, coupled with appropriate peer review mechanisms, this would enable the development of a strong science base in the field.

Moreover, these activities would provide opportunities for research staff located in both the rail sector and academic and research institutions, and could also contribute to building relationships between universities and research-based institutions and the industry, including formal organisations and informal networks. This would result in an increase in the overall number of high-quality jobs across the European economy.

Further, R&I activity at TRL 1-3 is particularly important in generating new ideas that could have practical applications in the future. The activities covered by the S2R JU's IPX on system architecture indicate some areas that might be investigated further under Horizon Europe. These include for example the use of block chain technology in the management of

remote condition monitoring data. There is a need to move away from the high cost evolutive maintenance of the sector to a virtuous cycle of R&I, where rail becomes permeable to the introduction of new solutions and ideas.

Stakeholder opinion

Among the respondents to the Open Public Consultation a majority of business organisations (both large organisations and SMEs), business associations, academic and research institutions, EU citizens and public authorities considered the creation of new scientific knowledge and capabilities by the candidate institutionalised partnership for the rail sector to be relevant or highly relevant. Most of these groups also expected the partnership to create high quality jobs in the sector, although public authorities were less persuaded of the importance of this impact.

Economic/technological impacts

- An increase in rail's modal share of passenger and freight markets
- An improvement in the competitiveness of the RSI
- An increase in rail industry direct and indirect employment
- Creation of new business models and opportunities for the rail stakeholders

Overall, this initiative would lead to a more customer-oriented and market-focused delivery of R&I and to an improvement in the competitive position and market share of rail services in European transport markets, including both passenger and freight markets, and an improvement in the global competitiveness of the RSI.

Should the initiative be successful, the future generation of rail operations and services will create value for the stakeholders as well as for the users of the rail systems. A performance based approach in the revenue apportion should be re-considered and should also result in reducing the public budget envelope invested by Member States annually in each rail system, estimated at EUR 40 billion per year.

It would also encourage greater involvement of SMEs, who have the flexibility to develop innovations and bring them to market relatively rapidly, and of technology-based organisations outside the rail industry, including start-up, who can increase industry awareness of emerging technologies with potential applications in rail.

The initiative would also provide a platform for planning the progression of R&I activity through the TRLs, with the development of internal strategic plans defining the transition from fundamental research, through the development stage, to demonstration and offering to the sector migration plans for future deployment, outside its remit. Finally, it will enable a more effective leveraging of the Union funding, since stakeholders would be more confident of the potential returns from supporting the initiative if their contribution is part of a collaborative effort reflecting differences in capability and expertise.

Societal impacts

- Reductions in the environmental impacts of transport
- Improvements in the safety, security and health of EU citizens
- Affordable and accessible mobility and connectivity

The initiative would be particularly important in achieving sustainable development goals, since a significant increase in the modal share of rail (especially for freight) would reduce

the demand for less environmentally friendly forms of transport (such as road). In addition, an increase in R&I activity focused on rail freight and intermodal transport is expected to have broader societal impacts, leading to innovations that enhance the attractiveness and accessibility of these services for existing and potential users.

Environmental impacts

Given that rail transport already has a good environmental impact, much of the additional positive environmental impact of R&I would be achieved through making rail more attractive (for both passengers and freight) and thus attracting traffic volume from less sustainable modes of transport.

It is not about rail, whose energy and climate neutrality performance are out of reach for many other modes of transport, it is about making rail more attractive (for both passengers and freight) thus interacting and integrating with other modes of transport to transfer volumes and maximize the overall environmental performance of mobility and transport.

R&I activity focused on various elements (including interfaces of rail with other modes) has the potential to improve the quality of the urban environment in several ways. In particular, the provision of a more integrated transport network including cities across Europe would reduce the need for car travel, reducing congestion and improving air quality while contributing to target reductions in greenhouse gas and other emissions, and noise.

Similarly, greater innovation in the rail freight industry, suitably focused on the needs of the industry's customers, could substantially increase service quality, in such a way that logistics companies and shippers would consider rail as an alternative to road across a much wider range of markets and distances than at present. This effect would be reinforced if innovation also improved the efficiency of freight services and require to include non-rail actors to achieve it. Taken together, these effects could significantly reduce the level of road freight traffic, particularly on inter-urban and inter-regional routes, thereby contributing to a reduction in greenhouse gas and other emissions, and noise.

Social impacts

By putting a greater emphasis on the integration of national, regional and local rail systems with other modes, including through the development of collective transport systems that combine conventional rail with new services such as flexible mobility, the initiative would greatly improve connectivity within and between Member States. This would benefit EU citizens, including persons with reduced mobility (PRMs), by enabling greater freedom of movement, notably for those living in peripheral regions and remote locations whose journey opportunities would otherwise be limited.

Enhancing connectivity would provide access to a wider range of opportunities for employment, education and leisure. It would similarly promote the broader well-being of the citizens, for example by improving air quality. In addition, given the extent that R&I activity is directed towards improving the safety and security of collective transport services, users of such services would benefit from a safer travelling environment and reductions in the level of service disruption. Further, the increase of the efficiency and reduction of costs would make travelling by rail more affordable and accessible to everyone and hence increase its social inclusiveness and attractiveness compared to other modes.

6.4. What is needed to achieve these impacts – Key functionalities needed

Given the focus of the impact assessment on comparing different forms of implementation, the identification of “**key functionalities needed**” allows making the transition between the definition of the objectives and what would be crucial to achieve them in terms of implementation. These functionalities relate to the type and composition of actors that have to be involved, the type of range of activities that should be performed, the degree of directionality needed and the linkages needed with the external environment.

6.4.1. *Type and composition of the actors to be involved*

Inclusion of the full range of rail stakeholders, and some key actors dealing interfacing with rail, is essential to leverage all relevant expertise and capability, and result in R&I outputs that address a broader set of needs than in the past, for transforming rail’s system architecture, increasing emphasis on freight and digitalisation and enhancing focus on deployment of innovative solutions. A comprehensive and balanced representation of the sector (also geographically) would also facilitate the broad acceptance of the solutions developed. The main categories of stakeholders that should be involved are:

- The operating community: European rail infrastructure managers, Rail Undertakings;
- Manufacturers of rail systems or components, contractors and service providers (e.g. maintenance activities) covering the full spectrum of the value chain, from SMEs to large integrators;
- More SMEs and start-ups which can introduce agile innovation within the rail system, including those coming from different domains of activity;
- The Scientific Community;
- Freight forwarders and logistic service providers;
- EU standardisation bodies (e.g. CEN, CENELEC and ETSI) to act on the outcomes of research and innovation activities generated by the partnerships to facilitate the evolution of EU regulation, and to anticipate standardisation activities that can accelerate the market uptake and remove barriers.

There may also be a need to change the profile of stakeholder participation, as well as the geographical diversity, for example by more flexibility in the rules governing participation to ensure that specific gaps in expertise can be filled effectively and efficiently.

The initiative would require the long-term commitment of participating stakeholders to deliver solutions ready to enter industrialisation, operations and deployment. As explained above, a wide range of actors in the rail system, from across the rail supply industry and operational sectors should participate, in order to develop a “system of systems” approach, and that stakeholders familiar with the outputs of, for example, a given development project have a role in the subsequent demonstration programme to achieve a substantial impact during the next decade.

A series of stakeholders, members as well as non-members of the current S2R JU, already expressed their commitment to contribute (also financially) to a future initiative on rail R&I. Further, sectoral association expressed in position papers their support for the initiative.

While the initiative is industry driven, particular attention will be paid to the cooperation with Member States, which is important not only for the fast implementation of the developed solutions but also for avoiding duplication and create more synergies between activities at national and European level. The participation of state-owned companies will ensure the leverage of some national programmes. Special focus will be put on promoting further participation of stakeholders from EU-13 for example through Large Scale Operational Demonstrations.

6.4.2. *Type and range of activities needed*

The initiative should be a catalyst to address present and future challenges in the transport sector and improve mobility across Europe.

The initiative aims at transforming rail's system architecture, increasing emphasis on freight and digitalisation and enhancing focus on deployment of innovative solutions. Focus on these areas at the level of the partnership is vital since deployment of innovation affecting the *systemic* elements of rail (as opposed to improvements in individual components/vehicles) requires many or all actors in the rail system to make coordinated changes – otherwise trains and track no longer work together, or interoperability between different lines is lost. Such coordinated change is only possible where the industry has collectively agreed on the way forward. As explained above, development of rail freight is a key element of the Green Deal – but the economic performance of the sector is currently poor, so investment in innovation unattractive on a purely commercial basis: hence again the need for EU Partnership intervention.

The following will be particularly important in meeting the identified general and specific objectives:

- Automatic Train Operation (ATO), boosting safety and capacity and resulting in significant (up to 30%) energy savings, deployed in different forms from unmanned vehicles to unmanned self-driving systems;
- New traffic management systems, which maximise performance by allowing trains to run together as effectively as possible through optimising the speed and movements of trains on the network. In particular it should boost the reliability of very long distance trains – in particular those running internationally – and enhance the ability of networks to recover from disruption;
- Control Command Signalling harmonisation at European level – bringing the sector together to develop the operational concepts for passenger and freight services, functions driven by one shared system architecture, and associated specifications and standards, subsuming and replacing previous initiatives;
- Further exploration of the benefits of relevant technologies, for example 5G, digital maintenance, automation, cybersecurity, the realisation of which can be expected to both increase the efficiency and competitiveness of European rail sector and strengthen the technological lead of the European RSI;

The development of technologies supporting a step change in the competitiveness of the rail freight sector, such as management of integrated information to enhance the

customer experience, remote monitoring of the cargo environment, automated loading and unloading and remote monitoring of wagon condition⁷².

The delivery of these activities would require coordination across the TRLs, with work focused on industry and market needs, and focused demonstration activities designed to provide robust evidence of the potential benefits of innovations for users and providers of rail services. It has to be noted that, in the context of the European RSI, SMEs manufacture mostly rail components. A higher TRL would foster the SMEs participation in the initiative, since the results of their research activities would be more likely to be taken up by large manufacturers and system integrators.

It would also be important to establish links with other, related fields of research and associated policy interventions, for example through the specification of joint R&I programmes funded under two or more initiatives with a common focus on a particular field of research or technological application.

6.4.3. *Priority setting system and level of directionality required*

The initiative should enable or support the following:

- Alignment of the R&I strategy with EU policy objectives: the initiative should support the completion of SERA, in particular through the development of a long-term shared vision of an integrated European railway system: the further development of Europe's railways would need to be based on a whole-system approach to investment, cutting across the various interfaces, which recognises the long-lived nature of railway assets.
- Maximum leverage of available resources: the initiative will also need to ensure that limited resources available for R&I are used as efficiently as possible, and that EU funds are supplemented by financial and/or in-kind resources provided by the RSI, the rail transport industry and technology-based organisations from outside the rail sector.
- An implementation approach with a strong and committed governance led by the Union, and with an inclusive participation. This would also require to define the procedures that would allow an efficient and effective implementation. Transparent decision-making and visibility of outputs: the initiative must be supported by decision-making processes that involve all relevant stakeholders and ensure clear accountability for results. It will also need to be subject to clear rules governing intellectual property, striking a balance between protecting organisations making substantial investment in R&I and ensuring that the outputs of individual projects are sufficiently visible to enable further development and high rates of market take-up.
- Dialogue at the national and international level: the initiative must enable effective dialogue between those engaged in R&I activity and those responsible for rail policy and regulation at the international and national level (including international standards bodies). Efforts should be made to ensure a robust and effective participation of Member States and organisations from EU-13.

⁷² See, for example, Rail Freight Forward, 30 by 2030: Rail Freight Strategy to Boost Modal Shift, available at: <https://www.railfreightforward.eu/about-rail-freight-forward>, for a discussion of how digital technology, together with other factors, could increase the modal share of rail freight to 30% by 2030.

6.4.4. *Coherence needed with the external environment*

In order to maximise complementarities and synergies with all concerned sectors, clear and strong collaboration with other initiatives and EU programmes is key in order to reach the expected impacts.

The following provide an illustration of the possible synergies between R&I in rail and other areas:

- Application of digital technology, starting from improving the functionality of ERTMS.
- Exploring complementarity with road, maritime and air transport –exploit the benefits of different modes at different stages of the journey and minimise environmental impacts.
- Exploiting developments in battery and fuel cell technology and other forms of power that has applications in different parts of the transport sector. It is important that the potential benefits for rail of further developments in different sources of power are fully explored. There could be scope for joint programming of R&I activity with the Batteries partnership, recognising the potential for greater use of battery and hydrogen fuel cell technology to reduce the need for investment in electrification of rail infrastructure.
- Synergies with other programmes and initiatives would be needed, in particular: the Digital Europe Programme (DEP) that will focus on reinforcing Europe's capacities in high performance computing, artificial intelligence, cybersecurity and advanced digital skills and ensuring their wide application across the economy and society.
- Synergies with other funding sources and financing mechanisms that would support innovation in particular the Connecting European Facility (CEF) for deployment of the innovative solutions.
- Synergies with the European Regional Development Fund (ERDF) and Cohesion Fund (CF) in order to increase economic and social cohesion and reduce imbalances.
- Global synergies related to new emerging and non-traditional land transport technologies such as hyperloop, hyper-speed maglev, pods' concepts, etc. where experience is shared at global level to accelerate possible future new business models and services that can revolutionize transport and mobility, while maintaining a European know-how competitive edge.

7. WHAT ARE THE AVAILABLE POLICY OPTIONS?

This section describes the specific functionalities that could be provided under the baseline scenario of traditional calls and the different options of different types of European partnerships.

7.1. What is the baseline from which options are assessed?

The baseline scenario used in this impact assessment is a situation without a Partnership and only traditional calls of Horizon Europe. Given that there is a predecessor Partnership as well as other funding sources in the area, these will continue generating effects even if there is no new Partnership. In particular it is expected that these already existing initiatives will still create effects on the ongoing evolution of the rail system, the digitalisation of the sector and the ongoing efforts to meet the EU Green Deal objectives. However, in the absence of a new Partnership, these benefits would be limited in time and their scope is going to be significantly reduced. This is taken into account in the effectiveness assessment.

In parallel, the baseline situation means that the current implementation structure of the Article 187 would be closed, which bears winding down and social discontinuation costs. There would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is taken into account in the efficiency assessment.

Table 2 - Key characteristics of the baseline – Option 0

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • The Commission would need to prepare or delegate the preparation of the Strategic Research and Innovation Agenda (SRIA) consulting extensively with a wide range of stakeholders to translate the strategic R&I agenda for rail into annual work programmes. • There would be no formal and financial commitment from partners to jointly develop and implement the Programme defined in the SRIA. • A well-defined process would be needed to ensure that the Programme Committee responsible for mobility was properly informed about R&I priorities, including key demonstration programmes. • An evolving profile of participation would be needed, with different consortia forming at different stages to take different types of activity forward, in order to maximise the expected outputs.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • Implementation would rely on standard infrastructure underpinning the procedure of calls under the work programme, drawing on resources of relevant executive agencies and Commission IT systems. • Calls for proposals would be part of the work programmes of Horizon Europe. • Transparency and open publication of results would ensure their availability to interested parties. • Dissemination of knowledge and share of practice would happen predominantly among partners within the project consortia. • Uptake of outcomes into technical specifications for interoperability (TSI) and rail standards would happen sporadically and be heavily dependent on the objectives and quality of results of individual projects. • Contribution to the systemic and integrated transformation of the European rail sector would depend on the level of participation in and quality of individual projects.
Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • The governance structure and the lack of formal commitment from private partners would not fully enable the implementation of the long-term vision defined in the SRIA. Specification of calls for activity at higher TRLs, particularly demonstration programmes, would need substantial input from industry. • Calls would need to take into account the results of the S2R JU to ensure continuity where appropriate. • R&I activity would focus on the short to medium term needs of the sector in alignment with the EU policy objectives, although it would also include fundamental research. • Commission input into specification and oversight of calls would help to ensure alignment with overarching policy objectives but full integration with other programmes would require additional coordination.
Securing effective leveraging of resources (additionality)	<ul style="list-style-type: none"> • Progress of R&I effort would depend largely on EU funding, with no expectation of significant leveraging of industry support. • Given more limited funding than in the past, critical R&I priorities would need to be identified at the outset.
Key differences compared to the current situation	<ul style="list-style-type: none"> • No formal and financial commitment from private partners to implement the long-term vision defined in the SRIA. • Limited participation based on the composition of ad hoc consortia for specific projects. • Sporadic translation of projects results into standards and TSIs. • Piecemeal approach to R&I (as opposed to the current systemic approach). • Lack of long term vision for the transformation of the European rail system. • Increased reliance on EU funding as a result of limited leveraging of industry support.

- Limited synergies with other Partnership and EC Programmes (e.g. CEF).
- Sector fragmentation due to the creation of barriers between different rail segments, undermining the overall performance of the network
- Long term phasing out of national barriers undermining the contribution of rail to the Union policies, in particular the Green Deal.
- Increasing operational cost of the rail systems to the detriment of public budget and finances

7.2. Description of the policy options

Option 1 - Co-programmed European Partnership

Table 3 - Key characteristics of Option 1

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • The option would encourage participation of some key stakeholders committing to jointly support the development and implementation of a R&I programme based on common strategic R&I agenda. • It would need to consult with a wide range of stakeholders to ensure that the R&I agenda, and ultimately the work programme, was aligned with industry and market needs. • It would offer some degree of flexibility to change the profile of participation) over time, thanks to the possible leading role of sector Associations, with new partners joining in response to emerging results and changing priorities.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • Implementation of EU funded R&I agenda would rely on standard administrative infrastructure underpinning the calls under the work programme procedure, drawing on resources of relevant executive agencies and Commission IT systems. • Calls for proposals would be part of the work programmes of Horizon Europe. • Partners would implement their additional activities separately. Sector Associations could provide back-office with relevant functionalities to run the Partnership under Horizon Europe standard implementation would ensure transparency and open publication of results for the interested parties.
Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • The governance structure and the formal commitment from private partners could enable the implementation of the long-term vision defined in the SRIA, provided that a wide range of partners join the Partnership. • Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from the various partners to achieve an appropriate balance of activity directed towards different markets (e.g. freight transport). • The partnership would be responsible for ensuring that priorities for calls were specified in line with R&I priorities, including demonstration programmes. • R&I activity would be likely to focus on the medium-term needs of the sector combined with EU policy priorities. • Programme Committee responsible for mobility or similar configuration would have important role in ensuring alignment with overarching policy objectives and coordination with related programmes. • Limited participation from sector's partners could result in limited efficiency to develop outputs that would be rapidly applied across the network.
Securing effective leveraging of resources (additionality)	<ul style="list-style-type: none"> • Aspirations for partner contributions would be clearly defined at the outset in the contractual arrangement. • In-kind commitments from private partners are expected to match Union contribution. • Expected in-kind contributions from the private sector would be identified in the work programme.

Key differences compared to the current situation

The Co-Programmed partnership (Option 1) would entail the dismantling of the current S2R JU with the following consequences:

- The implementation of a common vision and ambitious objectives in the area would be less efficient and take longer (if a common vision could be developed at all);
- The basis for R&I cooperation under a stable structure would disappear;
- Large scale R&I actions (pilots, platforms) could not be implemented, affecting the coverage of TRL 5-8 and diminishing the impact of the initiative;
- EU support to the area would move from a shared long-term commitment with the industry to a full financing by the EU, with a much lower volume of resources available;
- Combined European/national public funding of actions would not be possible;
- Winding down and discontinuation costs of the current S2R JU (see rationale at Section 8.2 - Efficiency)

Option 2 – Institutionalised European Partnership under Article 187 TFEU

Table 4 - Key characteristics of Option 2

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • The option would enable participation by all key stakeholders to jointly support the development and implementation of a programme of research and innovation activities contributing to the specification and delivery of the SRIA. • In order to increase the use of results in national contexts, the rail operating community should contribute to the definition of needs, specifications, requirements, and interfaces together with the rail supply industry and research community. • This option would enable the development of high-TRL solutions closer to the market, thus fostering SME’s participation in the Programme, since the results of their research activities are more likely to be taken up by large manufacturers and system integrators. • The governance structure would allow the delivery of sector’s needs and EU policy objectives. It creates an interface for consulting stakeholders on R&I priorities and the work programme in a transparent, structured and targeted manner, ensuring that they are aligned with industry, research and market needs and with the agenda of other partnerships and sectoral programmes. • Becoming a partner/member would be less flexible than under other options, but it might nevertheless be possible to change the profile of participation over time, with new partners joining to support new areas of activity in response to emerging challenges and evolving priorities. • The definition of an integrated R&I Programme looking at internal and external interfaces would attract rail actors of all segments who will find their needs answered. An agile approach should be put in place to address the needs of the beneficiaries to achieve an ambitious programme. • The definition of the shared vision driven by the Union mobility and transport policy based on a functional system architecture will attract the participation of sector representatives setting the basis for a more delivery oriented R&I Programme.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • A dedicated administrative structure would be established to coordinate the specification of R&I activity, manage implementation and report on the results (with administrative expenditure subject to rules relating to its level and distribution). This could be mitigated through the use of existing structure under S2R JU and the setting up of a joint back office for a number of JUs. • Calls for proposals would be published broadly by the administrative structure allowing efficient coordination among stakeholders. • Transparency and open publication of results would ensure their availability to interested parties. • The creation of a community of stakeholders, with potential diffusion activities managed by the partnership structure would enable the share of knowledge and practices. • The interface with national authorities, ERA, European and international standardisation bodies would ensure that results would enter properly the pipeline of regulatory or

	<p>standard framework for market uptake and impact.</p> <ul style="list-style-type: none"> • An Institutionalised Partnership would make full use of available financial instruments within the limits of the Horizon Europe and of the Partnership Basic Act, building on the experience of the S2R JU (e.g. the use of the lump sum model, prizes, etc.). • Dissemination and communication activities will be not limited to typical inwards project events, such as in H2020 or future HE programme, but resources would be commingled to leverage a common investment and connect with other sectors and modes. • The administrative structure would become the single coordinating body to converge the sector together towards a shared vision on concept of operations, ensuring a sector-driven action led by the Union policies towards a major transformation of railway.
<p>Ensuring alignment with R&I agenda (directionality)</p>	<ul style="list-style-type: none"> • Based on the long-term joint agenda, the partnership would be responsible for defining a work programme fully in line with the R&I priorities identified by the industry, combining activities across the TRLs (including key demonstration programmes) and in different areas (e.g. freight transport). • In order to achieve a balanced approach between blue-sky and applied research, the Institutionalised Partnership would have the mandate and resources to allow for the completion of the R&I cycle, including industrialisation of innovative solutions. • The work programme would reflect the medium to long term needs of the sector aligned with EU policy priorities, drawing on the perspectives of different stakeholders. • The work programme would build on, but not be constrained by, the current programme to ensure continuity where appropriate. • Commission participation in the partnership governance arrangements and approval of the work programme would help to ensure alignment with overarching policy objectives and enable integration with other programmes.
<p>Securing effective leveraging of resources (additionality)</p>	<ul style="list-style-type: none"> • Legally binding funding requirements would be clearly defined at the outset, with private sector partners expected to provide a substantial part of the resources through in-kind and/or financial commitments. • An institutionalised partnership would allow investments for long-term research with the medium or high risk of failure. Also, it would help to recruit and maintain research teams for research activities with a medium or high risk of failure. • An institutionalised partnership would allow a structure aimed at the deployment of innovation. In particular, strong coordination with the CEF Programme would help filling the qualitative gap to move from TRL 7 to full deployment. • An institutionalised partnership would allow reducing the overall cost of bringing research and innovation to the market, as it would involve in its processes ERA and standardization bodies.
<p>Key differences compared to the current situation</p>	<ul style="list-style-type: none"> • The administrative structure of S2R JU would be taken over by the new institutionalised partnership. • Governance, administrative procedures and practices will be adapted as to ensure that operations are as transparent and efficient as possible. • The governance structure would reflect the enhanced need for a systemic approach e.g. by including a system pillar steering group.

7.3. Options discarded at an early stage

The co-funded partnership and an institutional partnership created under Article 185 of the TFEU are not considered relevant for the impact assessment of the Transforming Europe's Rail System partnership. This is because of the need to secure the engagement of private sector and other commercial organisations in the co-funding, programming and delivery of R&I, not least because of the key role of such organisations in both the delivery of rail services in Europe and the supply of rail-related products and services in global markets. As the only forms of partnership in which the private sector can participate are the co-programmed partnership and the institutionalised partnerships established under Article 187,

the analysis in the following section is restricted to a comparison of these options with the baseline option of calls under the Work Programmes of Horizon Europe.

8. HOW DO THE DIFFERENT POLICY OPTIONS COMPARE TO ACHIEVE THE EXPECTED IMPACTS?

Based on the objectives pursued by the initiative and the key functionalities identified to be able to achieve them, each option for implementation is assessed in terms of effectiveness, efficiency and coherence compared to the baseline scenario of traditional calls. The analysis is primarily based on the degree to which the different options would cater for the key needed functionalities. All options are compared to the baseline situation of traditional calls, which is thus consistently scored at 0 to serve as reference point.

8.1. Effectiveness

To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. This section considers to which extent the different policy options would allow delivering these expected impacts – confronting what is needed (functionalities) with what each form of implementation can provide in practice. The assessments in this section set the basis for the comprehensive comparative assessment of all retained options against all dimensions in Section 6.4, based on a scoring system⁷³.

Scientific impact - Creation and diffusion of high-quality new knowledge, skills, technologies and solutions to global challenges

Under the **baseline option** of traditional calls under Horizon Europe the volume of publications from European universities and research-based organisations is expected to increase at a rate similar to that observed during previous Framework Programmes. Given that this option does not provide a consistent and coordinated ecosystem of stakeholders, it could deliver significant outputs for low and medium TRL, if a clear agenda is set up.

However, the scientific impact under this option would be limited by a number of factors:

- It would be difficult to coordinate the wider participation among stakeholders, since the composition of consortia responding to the calls under Work Programme could not be easily directed and managed according to a common strategy.
- It would not be possible to provide technical solutions and sufficient knowledge to address, since there would be some dislocation between calls launched at different times and no guarantee that the appropriate stakeholders would be involved throughout a given research programme.
- The effective diffusion of any results obtained would be challenging given the fragmentation at project level and the lack of coordination at programme level.

Against this background, Europe’s contribution to the knowledge base is expected to develop in a fragmented manner under the baseline option, with China continuing to

⁷³ A more in depth and detailed analysis of each policy option is provided in Technopolis Group (2020)

strengthen its position in the publication of fundamental research and to dominate the creation of new intellectual property.

Given the higher degree of stability and based on the feedback received in various consultation processes, a greater degree of participation is expected under a European Co-Programmed Partnership than under the baseline option. The scientific impacts under this option would probably be greater than those estimated under the baseline option, with European universities and research-based organisations having easier access to the Programme, thus making a stronger contribution to the volume of publications and the RSI registering marginally more patents and industrial designs as well as possible creation of jobs. Its score would therefore be good compared to the baseline with +.

However, the volume of creation and diffusion of high-level knowledge making a scientific impact would again be constrained by the partial participation of key stakeholders from the rail sector. This option would therefore be subject to many of the same limitations as the baseline. Its score would therefore be similar to the baseline with 0.

An Institutionalised European Partnership established under Article 187 TFEU would be subject to a well-defined legal and financial framework, with a wide range of partners contributing resources in accordance with legally binding requirements relating to the proportion of EU and partner funds, set out in a Council Regulation.

The coordinated involvement of research and industry actors with a long-term commitment, could contribute to the emergence of new applications and to continuous efficiency, quality and reliability improvements in applications and equipment. This impact will be even higher compared to the S2R JU, in light of the stronger system focus of the new Partnership. This would in turn also have an impact in terms of creation of high-quality jobs. The score of Option 2 would therefore be high compared to the baseline with ++.

In addition, creation of networks linking universities and research-based organisations under the coordination of the future Partnership, is expected to strengthen the scientific impact of this option. This, in turn, can encourage interest from organisations that have not participated in the current S2R JU, including SMEs, start-ups and entities from outside the rail sector, resulting in a more dynamic process of exchange and collaboration. The score of Option 2 would therefore be high compared to the baseline with ++. The score for the scientific impact for each option is presented in Table 6.

Table 6 - Overview of the options’ effectiveness compared to the baseline -Scientific impacts

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187
Increase in number of high-quality jobs	0	+	++
Strengthened pipeline of potential innovation	0	0	++

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

Economic/Technological impacts - Foster all forms of innovation and strengthen market deployment of innovative solutions

The technological and economic impacts under the **baseline option** of traditional calls would be limited by the difficulties of coordinating wider stakeholder participation and

market uptake of innovations and strengthening collaboration in accordance with a long-term strategy.

In addition, lack of participation on the part of some stakeholders would reduce the level of investment in R&I during Horizon Europe as compared with that under Horizon 2020. Progress towards disruptive innovation, for example through delivery of the kind of efficiency, punctuality and capacity targets previously defined for the S2R JU, would therefore be considerably slower.

The market take-up of innovation is not expected to increase substantially under a co-programmed European Partnership (**Option 1**), although some increase might be expected given a more structured approach to industry participation compared with one based entirely on traditional calls under the Work Programme. The estimated take-up rate between 45% and 60%⁷⁴, represents a significant but not necessarily transformative improvement on the rate achieved before Horizon 2020 and reflecting the degree of uncertainty surrounding the impact of this option⁷⁵.

The European RSI's technological lead is expected to be eroded under this option, since it would not enable sufficient incremental investment in R&I, over and above that which the industry would anyway undertake, to deliver a step change in the level of both fundamental research and market-focused development. Hence, while the marginal increase in intellectual property could strengthen the industry's position in some countries, for example those where there is potential to deploy ERTMS, this would probably be insufficient to address the challenge from countries such as China and Japan. The score would therefore be good compared to the baseline with +.

Since the stable governance framework of an Institutionalised European Partnership under Article 187 TFEU (**Option 2**) would ensure a more structured approach in terms of number and composition of actors, coordination of activities and coherence with external environment and other ongoing activities, it could be expected to deliver substantially higher technological and economic impacts, including better leverage of EU funding. In particular, wider, more focused and more structured participation of stakeholders, including key actors within the rail transport industry as well as SMEs and technology-based organisations, combined with better coordination of R&I effort along the value chain, would enable a substantially higher level of demonstration activity. This includes a strong focus on the speed-up of deployment of innovation and market uptake to implement a systemic transformation of rail transport. Moreover, wide and coordinated participation will allow the development of a system of systems and a coordinated approach to transform the rail sector's system architecture, resulting in more tangible economic and technological impacts compared to the S2R JU. The involvement of Member States will be essential in this respect, as they will be in a position to foster the deployment at national level of innovative solutions developed at European level in the Partnership.

The long-term vision and related financial stability provided by an institutionalised partnership would be key to foster stakeholders' involvement, in the aftermath of the Covid-19 breakout and its expected negative economic impacts which could include cuts in the

⁷⁴ Source: Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Candidate Institutionalised European Partnership on Transforming Europe's Rail System - Study for the European Commission, DG Research & Innovation

⁷⁵ There is no direct experience of a co-programmed partnership in the rail sector and hence no firm evidence on which to base the market take-up assumption.

resources invested in R&I by the sector. Whilst it is too early to say if the Covid-19 crisis will finally lead to major supply chain changes, there are good reasons to assume that ultimately economies of scale will still largely prevail in most sectors. Structural issues such as repatriation of production, questioning of global supply chains and globalisation in general will however all be under review. As a result, digitalisation might be accelerated as opportunity also for the rail sector for new efficiency gains. The score of the option would therefore be high compared to the baseline with ++.

In view of the long term commitment of partners of a JU and the additional resources available to it, such a partnership should target a market take-up rate of between 50% and 100%. The estimate impacts of this option assume a take-up rate of between 50% and 75%⁷⁶ and that the efficiency targets set for the current JU are achieved by 2031. The score would therefore be high compared to the baseline with ++.

These improvements lead to a significant contribution to the increase in the competitiveness of the rail transport industry, with rail's share of passenger traffic rising to 10% or more and its share of rail freight traffic reaching around 20% by 2031, and contributing to the Green Deal objective to shift a substantial part of the 75% of inland freight carried today by road onto rail and inland waterways. The increase in rail industry and other employment under this option is also substantially higher than under those previously discussed. The score would therefore be high compared to the baseline with ++.

Table 7 shows the estimated range of technological and economic impacts of each option. Economic and technological impacts have been estimated using a model developed for a European Commission 'Study on the Cost and Contribution of the Rail Sector'⁷⁷. The model has been adapted to investigate the effect of different combinations of transport cost savings and investment (see Annex 4 for a detailed description of the model). These values do not consider the potential impact and consequences of the Covid-19 pandemic, which are still under assessment.

Table 7 – Technological and economic results and impacts

Range of values in 2031		Option 0	Option 1		Option 2	
		Value	Lower	Upper	Lower	Upper
Results	Reduction in railway costs compared to baseline scenario (€ bn)	0	11.3	15.2	33.2	51.0
	Increase in railway investment compared to baseline scenario (€ bn)	0	5.7	7.6	16.6	25.5
Impacts	Increase in passenger traffic compared to baseline scenario (bn passenger-km)	0	23	32	74	123

Increase in freight traffic compared to baseline scenario (bn tonne-km)	0	23	32	73	122
Increase in total employment compared to baseline scenario by 2031 (thousands of people).	0	201	269	591	904

For each option, the score for the potential to achieve economic/technological impacts is presented in Table 8.

Table 8 - Overview of the options' effectiveness compared to the baseline - Economic/technological impacts

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187
Increase in rail's modal share of passenger/ freight markets	0	+	++
Improvements in the competitiveness of RSI	0	+	++
Increase in rail industry and wider employment	0	+	++

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

Stakeholder opinion

The Open Public Consultation responses provide further support for the view that a well-defined legal structure of the kind underpinning an institutional partnership would increase the economic and technological impacts of the initiative. A substantial majority of business organisations of different sizes, business associations, academic institutions, public authorities and EU citizens considered that such a structure was either relevant or very relevant for achieving more effective and faster implementation of the initiative, increased financial leverage, better links to both regulators and practitioners on the ground, more long-term commitment from partners and harmonised standards.

A majority of the interviewees representing train operators, infrastructure managers and the RSI considered that an institutionalised partnership was essential if EU funding of rail-related R&I was to have a transformative economic and technological impact on the sector. In the view of a number of key stakeholders involved in the S2R JU, the legal framework established under this approach, together with the associated commitments in respect of the provision and allocation of funding, was essential if major public sector stakeholders were to obtain internal and external approval for their participation. It followed that, in the absence of such a framework, these stakeholders would substantially reduce their support for, or even disengage from, an initiative to promote rail-related R&I under Horizon Europe.

Most of the organisations providing feedback on the inception impact assessment also strongly supported the implementation of an institutionalised partnership. They considered such a partnership to be significantly more effective in delivering economic and technological impacts, noting that it would be better placed to develop a long-term strategy for R&I investment, coordinate the contributions of different stakeholders and ensure efficient use and better leverage of EU funding.

Societal impacts - supporting and implementing Union policies, and the uptake of innovative solutions in industry and society to global challenges;

Under the **baseline option**, the net reduction in CO₂ emissions in 2031 is estimated to be between 0.4 and 0.5 million tonnes⁷⁸ (after taking account of the impact of increased traffic levels and the transfer of traffic to rail), with a value of Euro 18 - 24 million⁷⁹, reflecting the limited modal shift for both passenger and freight noted above.

Moreover, the option is unlikely to contribute significantly to the better integration of transport systems needed to enhance connectivity for EU citizens and materially improve the quality of life for the growing proportion of the European population living in cities. This will depend on the involvement of national rail operators, infrastructure managers and other transport service providers who can help coordinate the R&I activity needed to identify improvements in the interface between national and local networks. Such participation would be limited in circumstances where support for R&I was restricted to standard calls under the Work Programme.

Under a Co-Programmed European Partnership (**Option 1**), the net reduction in CO₂ emissions is estimated between 1.0 and 1.4 million tonnes in 2031⁸⁰, valued at Euro 50 – 68 million. This is approaching three times the reduction achieved under the baseline but still limited when set against total emissions from transport in a single year. The score would therefore be good compared to the baseline with +. This form of partnership would not allow the development of a system of systems and a coordinated approach to transform the rail sector's system architecture, due to the limited participation of stakeholders. In particular, it would not encourage the level of participation from urban transport operators and other stakeholders needed to transform transport systems and increase quality of transport and life within and between cities. The score would therefore be good compared to the baseline with +.

Thanks to a coordinated and market-oriented sectorial approach and a coordinated effort to deploy innovative solutions, the reduction in CO₂ emissions is likely to be more substantial under an Institutionalised European Partnership under Article 187 TFEU (**Option 2**) as significantly more traffic would be diverted to rail from other, less environmentally friendly, modes. The expected reduction is between 2.5 and 4 million tonnes in 2031⁸¹. This impact could be expected to increase if the competitiveness of rail services continued to improve beyond the period of Horizon Europe, hence making a substantial contribution to the achievement of the Green Deal objectives.

Moreover, thanks to the coordinating role of the Commission and the involvement of Member States, an institutionalised partnership would be more likely to deliver the

⁷⁸ Source: Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Candidate Institutionalised European Partnership on Transforming Europe's Rail System - Study for the European Commission, DG Research & Innovation

⁷⁹ Carbon is valued at €48 per tonne, based on Handbook of External Costs of Transport 2014.

⁸⁰ Source: Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Candidate Institutionalised European Partnership on Transforming Europe's Rail System - Study for the European Commission, DG Research & Innovation

⁸¹ Source: Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Candidate Institutionalised European Partnership on Transforming Europe's Rail System - Study for the European Commission, DG Research & Innovation

transformational change to national transport systems making the European railways cheaper, more reliable and more flexible, hence more attractive. In addition, it would significantly contribute to improving quality of the environment in European cities. The score would therefore be high compared to the baseline with ++.

Since one of the objectives of the candidate rail partnership is to increase R&I activities related to rail freight, one core element of the transformation to logistic on-demand services is the link between customer demand and logistic service supply. This requires seamless, digitized customer communication linked to the management systems of RU, IM, ports, clients and multimodal service providers which can be achieved by means of a wide coordination under an institutionalised partnership. The score would therefore be high compared to the baseline with ++.

Stakeholder opinion

For the most part, various categories of stakeholders participating in the interview programme and responding to the inception impact assessment considered that an institutionalised partnership would be best-placed to deliver a range of beneficial societal impacts, including a reduction in environmental emissions and better integration of the European transport system in the interest of EU citizens.

In the Open Public Consultation, a majority of respondents indicated that the Partnership would be very relevant for contributing to a cleaner mobility at lower costs, reduced noise, energy consumption and emissions. Both companies and academic institutions highlighted the importance of ensuring the competitiveness of the European rail industry at the global level while focusing on societal objectives (e.g. increasing the use of renewable resources) and demonstrating the practical benefits of rail-related R&I to a wide audience.

For each option, the score for the potential to achieve societal impacts is presented in Table 9.

Table 9 - Overview of the potential for achieving societal impacts

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187
Reduction in environmental impacts of transport	0	+	++
Improvements in safety, security and health of EU citizens	0	+	++

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

Expected impact on simplification and/or administrative burden

An Institutionalised Partnership would be capable to simplify the administration related to the membership participation in the research and innovation activities. A generic approach designed for a multibillion diversified Programme such as Horizon Europe with spread accountability and different funding tools would not match the expectations of a mission oriented programme such as rail Research and Innovation.

Expected impacts on fundamental rights

With a significantly strengthened integration of rail systems with other modes citizens would have greater freedom to pursue career, educational and leisure opportunities of their choice and to travel in a safe, secure and healthy environment. In addition, PRMs will be able to access such opportunities more easily. In addition, regional cohesion would be further enhanced, through collaboration in the Research and Innovation lifecycle as well as through the delivery of a new integrated rail system.

8.2. Administrative Costs/Efficiencies

In order to compare the policy options consistently in terms of their efficiency, a standard cost model was developed for the external study supporting the impact assessment for the set of candidate Institutionalised Partnerships. The model and the underlying assumptions and analyses are set out in the Common Part of this impact assessment, Section 2.3.2 and in the Methodology Annex 4. A dedicated Annex 3 also provides more information on who is affected and how by this specific initiative in line with the Better Regulation framework. The scores related to the costs set out in this context allow for a “value for money” analysis (cost-effectiveness) in the final scorecard analysis in Section 6.4. For the purpose of this analysis, the standard cost model is complemented with information based on the current experience of S2R JU, which contributes to providing a realistic estimate of costs of the future Partnership. Indeed, such analysis should take into due account the fact that initiatives deriving from an existing Partnership, such as Transforming Europe’s Rail System, would benefit from an administrative structure already in place and set up costs already borne, hence a significant overall cost reduction. In addition, for this specific initiative under the baseline scenario of traditional calls, there would be winding down and social discontinuation costs for the existing implementation structure of the current Article 187 initiative. These can be estimated at EUR 400.000. There would also be longer term financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. These can be estimated at EUR 3.5 million (EUR 1.6 million administrative costs, EUR 1.9 million personnel costs) per year of operation. The total running costs of the existing S2R JU cannot exceed EUR 27 million (50% from the EU and 50% from private Members through in cash, in kind and additional contributions). Private members will also contribute 50% to all administrative costs that would account for maximum 5% of operational expenditure. These costs are the baseline of the current S2R JU and should therefore be adapted on the basis of the ambition, programme and budget of the Transforming Europe’s Rail System candidate Partnership. In S2R JU, indicatively 30% of the funding is allocated to the operating community, whereas the supply industry and research community get approximately 70% of the available funds. Under the future Partnership, a more balanced approach in terms of funding distribution is envisaged.

Annex 3 provides additional information on costs and benefits of the preferred option. Overall it is estimated that the longer term cost savings from using traditional calls instead of an existing Article 187 initiative would considerably exceed the costs incurred for winding down operations. However, it should be also noted that higher costs of an Institutionalised Partnership result in a way more effective performance in terms of outputs for the benefit of European citizens and industry compared to other options. This overall situation is set as the starting point for the comparison of options. The score of this baseline scenario (traditional Horizon Europe calls) is set to 0 to be used as a reference point.

On this basis, the scores for the costs of the different options range from a value of 0, in case an option does not entail any additional costs compared to the baseline, to a score of (-)(-) when an option introduces limited additional costs when compared to the baseline and a

score of (-)(-) when substantial additional costs are expected in comparison with the baseline. In case the scores are lower than for the baseline scenario, (+) and (+)(+) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. Indeed, in terms of cost-efficiency, the Co-Programmed Partnership (Option 1) is 2 percentage points more efficient than the baseline; and an Article 187 Partnership is 2 percentage points less cost-efficient than the baseline. A score of + is therefore assigned for **cost-efficiency** to the Co-Programmed options and a score of (-) for the Institutionalised Partnership policy option.

Table 6: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Administrative, operational and coordination costs	0	0	(-)(-)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	+	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline.

8.3. Coherence

8.3.1. Internal coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with other actions, programmes and initiatives under Horizon Europe, in particular European Partnerships (internal coherence).

While some coordination of the activity could be achieved under the baseline option (**Option 0**), it would be difficult to ensure an effective progression of activity from fundamental research through development work to demonstration. This is a consequence of the difficulty of ensuring continuity between projects at different TRLs under a standard calls approach, not least because the parties responding to individual calls would typically be consortia formed on an ad hoc basis with limited knowledge of the broader strategic programme of R&I activity.

Similarly, coordination of R&I programmes with other initiatives, including any partnerships formed under the Climate, Energy and Mobility cluster or more generally under Horizon Europe, would be challenging, due to the fragmentation at consortia level. This option would allow a coherent approach through the Work Programme and strategic planning but would not enable a proactive approach in terms of activities which need more coordination (for example demonstration activities) and closer collaboration between research, industry and decision-makers.

While the memorandum of understanding underpinning a Co-Programmed European Partnership (**Option 1**) would reflect the technical content defined in the strategic research agenda, development and delivery of the work programme would rely on Commission

structures, with Member States approving the Work Programme under comitology procedure. Hence, the partnership would not have much control for the direction of rail-related R&I and it would be difficult for it to work with other partnerships within Horizon Europe to define an integrated work programme leveraging synergies in relevant areas. The score would therefore be good compared to the baseline with +.

An Institutionalised European Partnership under Article 187 TFEU (**Option 2**) would meet the functionality requirements described in *Section 4.4* more effectively and would therefore be better placed to deliver a more coherent long-term strategy for rail-related R&I, with the possibility to adjust its strategy considering the evolution of Union policies and stakeholders' needs. In particular, it would be able to call on dedicated management resources to develop the strategy and plan supporting work programmes in collaboration with other partnerships. This would ensure that the strategy could take account of links with key partnerships, such as ECSEL and 5G for digitalisation and automation, Clean Hydrogen and Batteries as alternatives for diesel trains and for autonomous new freight wagons and other transport partnerships concerning interfaces with other modes and multimodality. Synergies and cooperation with the Knowledge and Innovation Communities (KIC) would be established (e.g. with the urban mobility, energy and climate KICs) to increase demonstrations and facilitate deployment of technologies. Moreover, synergies and cooperation with the Missions could be established, in particular on Climate Change and Smart Cities. The score would therefore be high compared to the baseline with ++.

Stakeholder opinion

Stakeholders participating in the interview programme indicated that a future partnership would be able to cooperate more with other initiatives under Horizon Europe to leverage the benefits of technology that is not specific to the rail sector. One regulatory agency stressed the importance of developing a strategy and work programme that reflected the needs of a fully integrated transport system for Europe.

Responding to the Open Public Consultation, a majority of stakeholders stated that the legal structure underpinning an institutionalised partnership was either relevant or very relevant to the facilitation of collaboration with other partnerships under Horizon Europe. Support for this view was particularly strong among large business organisations and business associations, but it was also held by most SMEs, academic and research institutions, public authorities and EU citizens. A substantial majority in each of the same stakeholder groups confirmed that there would be scope for rationalising the activities of the candidate partnership for rail and to link it with other initiatives under Horizon Europe.

Respondents that are/were involved in a current/preceding partnership found a legal structure more relevant than other respondents when it concerned a faster to response to sudden market or policy needs as well as synergies with other programmes and collaboration with other partnerships.

Large companies showed a slightly higher relevance for implementing activities effectively, ensure better links to regulators, obtaining the buy-in and long-term commitment of other partners, synergies with other EU/MS programmes and collaboration with other EU partnerships than other open consultation respondents. Public authorities find it slightly less relevant to facilitate collaboration with other European Partnerships than other respondents.

8.3.2. External coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with their external environment, including EU-level

programmes and initiatives beyond the Framework Programme and/or national and international programmes and initiatives, but as well as with overarching framework conditions, such as regulation, standardisation, etc. (external coherence).

Under the baseline scenario (**Option 0**), it would be difficult to coordinate the development of a work programme taking account of parallel, related activity under the Digital Europe Programme (DEP), Connecting Europe Facility (CEF), European Regional Development Fund (ERDF) and Cohesion Fund (CF). Despite that under this option, some coordination with other European Commission activities is possible at the level of priorities, coordination at the level of implementation is somewhat limited or even not feasible. Finally, collaboration with national or regional initiatives such as national programmes or the coordination with regional clusters is not feasible under this option.

In a Co-Programmed European Partnership (**Option 1**), the barriers to coordination within Horizon Europe would extend to coordination with other programmes under Digital Europe Programme (DEP), Connecting Europe facility (CEF), European Regional Development Fund (ERDF) and Cohesion Fund (CF). The European Commission can contribute to some extent to the coordination with European initiatives outside Horizon Europe at the level of the strategy. The non-systematic participation of Member States provides the opportunity for coordination with the national programmes and initiatives and the regional clusters. Even if joint programmes could be agreed in principle, there could be no guarantee that work undertaken in response to open calls would be fully aligned with the specification of activity anticipated under other funding initiatives. The score would therefore be the same compared to the baseline with 0.

An institutionalised European Partnership under Article 187 TFEU (**Option 2**) has necessary structures and resources to ensure a continuous dialogue among all players, including international, national, regional and local authorities and therefore does provide a clear global framework to mainstream rail efforts into the Green Deal objectives. It would be able to explore opportunities for funding of programmes and projects under DEP, CEF, ERDF and CF and set provisions for systemic synergies between the Partnership and existing funding mechanisms. These synergies have been developed only to a limited and occasional extent in the S2R JU and would therefore be more systematically exploited in the future Partnership. In particular, a novelty compared to the S2R JU would be the setting up of a dedicated deployment manager function to ensure strong coordination and synchronisation with the CEF Programme, filling the qualitative gap to move from TRL 7 to full deployment. Increasing the chances of deployment of innovative solutions would result in increased attractiveness of the future Partnership for potential Members, including SMEs.

Moreover, the partnership would also be able to represent the interests of the rail R&I community in discussions with other relevant European institutions, for example the European Investment Bank. Under this option, the possibilities of coordination and

Stakeholder opinion

A majority of the stakeholders responding to the Open Public Consultation considered that establishing a specific legal structure for the candidate European Partnership was either relevant or very relevant to the facilitation of synergies with other EU and national programmes. This view was particularly strongly held by the larger business organisations and business associations as well as by EU citizens.

Interviewees also expressed the view that a future partnership would be well-placed to develop a dialogue with other EU initiatives, notably CEF, and that it could facilitate opportunities for collaborative funding using sources outside the scope of Horizon Europe. A limited number of the stakeholders providing feedback on the inception impact assessment suggested that an institutionalised partnership would be better able to take account of the activities of other, relevant EU agencies and organisations and to explore the potential for support for R&I from CEF.

exploitation of synergies offered by the Co-Programmed option are expanded by the existence of the central coordination level which can improve and extend the collaboration at the level of projects. More generally, as the partnership would be in a better position to facilitate links with a wider range of EU institutions, agencies and initiatives, the score would be high compared to the baseline with ++.

The scores for internal and external coherence are summarized in Table 12.

Table 12 - Overview of the options' potential for achieving coherence

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 3: Institutionalised Article 187
Internal coherence	0	+	++
External coherence	0	0	++

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

8.4. Tabular comparison of options and identification of preferred option

Building upon the outcomes of the analysis, this section presents a comparison of the options' 'performance' against the dimensions of effectiveness, efficiency and coherence.

Table 13 - Ranking of the policy options

	Items	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 3: Institutionalised Article 187
Effectiveness	Scientific impacts – increase in high quality jobs	0	+	++
	Scientific impacts – strengthened pipeline of potential innovation	0	+	++
	Technological/economic impacts – increase in rail's modal share	0	+	++
	Technological/economic impacts – increase in RSI competitiveness	0	+	++
	Technological/economic impacts – increase in total employment	0	+	++
	Societal impacts – reductions in environmental impacts	0	+	++
	Societal impacts – improvements in safety, security and health	0	+	++
	Coherence	Internal coherence	0	0
External - coherence		0	0	++
Efficiency	Overall cost	0	0	(-) (-)
	Cost-efficiency	0	+	(-)

Notes: Scores for effectiveness and coherence: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline. Scores for efficiency: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline

Overall the **institutionalised partnership established under Article 187 of TFEU is the preferred option** as it dominates all dimensions apart from efficiency. Moreover, while it has higher overall direct transparent cost (without considering the cost of discontinuation of the current Joint Undertaking, which would impact the two other options), it ensures better capability to meet the objectives than the other options thanks to a sufficiently inclusive governance structure and the possibility to define an integrated cycle of research and innovation up to TRL 9 allowing the delivery of sector's needs and EU policy objectives.

This option best ensures that private and public sectors remain fully engaged in the development and implementation of a long-term strategy for rail R&I, while encouraging participation from key stakeholders with access to significant financial and in-kind resources that they would be willing to commit under a clearly defined and stable legal framework. This is all the more a decisive factor at a time when the sector is struggling to recover from the Covid-19 crisis. The upstream financial commitment and the preparation of the technical content through the Master Plan ensure that both private and public sector remain fully engaged in the development and implementation of a long-term strategy for rail R&I.

An Institutionalised Partnership would be based on a publicly accessible programme providing full transparency regarding planning and activities. Building on the experience and lessons learned in the S2R JU, the R&I Programme will be based on a shared concept of operations, establishing a functional system architecture and working on innovation enablers to meet the identified technical and policy objectives. The Partnership will include a strong nucleus of Members, with a balanced participation of key stakeholder groups, selected in a transparent manner. Based on the current experience of S2R JU, the overall number of partners involved could be estimated at more than 400, representing the rail sector value chain and beyond. Enhanced openness compared to the current Partnership will be achieved by attracting entities that will be ready to commit to a shared programme, contributing with their expertise and breakthrough technologies.

Particular attention will be paid to increasing participation of SMEs and possible involvement and creation of start-ups to ensure that rail related new ideas, projects, and solutions would find an opportunity to connect with the sector and explore the possibilities to scale-up. In particular, the development of high TRL solutions closer to the market is expected to foster SME's participation in the Programme, since the results of their research activities are more likely to be taken up by large manufacturers and system integrators.

This form of partnership would continue to provide a stable framework for encouraging the participation of organisations from all concerned sectors (including those outside the rail industry), securing and allocating resources, managing a wide range of RD&I projects across all TRLs and creating synergies with other partnerships and initiatives within and outside the Climate, Energy and Mobility cluster. It is also considered appropriate to develop a strategy for rail in order to implement European Green Deal transport priorities, and especially the European climate commitment, and with several sustainable development goals.

The transition from the current S2R JU to the future European Partnership will be seamless, given that the overall organisational structure will need only some adaptations, rather than radical changes. In terms of content, the S2R JU will ensure a complete and efficient transfer of activities and results into the new Partnership. This should avoid as much as possible dead ends of ongoing activities.

The impact of the Covid-19 breakout on future EU collaborative research needs to be carefully assessed. The financial stability provided by an institutionalised partnership would be reassuring for the European rail sector stakeholders' and would encourage their participation in the programme, also given that they may be under financial pressure and therefore reconsidering their planned investments in R&I.

A comparison of possible stakeholders' commitment and Member States collaboration is provided in the Table 14 (list not exhaustive), under the assumption of EUR 900 million Union contribution and EUR 1550 million contribution from members other than the Union.

Table 14 – Possible contribution of stakeholders and Member States

	Quantitative contribution (Million Euros)	Qualitative contribution
Rail Supply industries	650	Providing the technological know-how and the human resources needed to perform R&I activities leading to future market solutions, covering the whole spectrum of applied research and demonstration activities.
Infrastructure Managers	350	- Providing the network related know-how, the human resources and the installed facilities to perform the R&I activities. - Participating in related and additional deployment activities funded under CEF.
Operators (mainline and urban)	350	- Providing the operations related know-how, the human resources and the rolling stock or installed facilities to perform the R&I activities. - Participating in related and additional deployment activities funded under CEF.
Other stakeholders (such as research organisations)	200	Providing the basic research know-how needed for lower TRL research and scientific expertise in the applied research work.
Member States		- Providing the Transforming Europe's Rail System JU through the State Representatives Group with information on relevant activities in Members States and contribution to generating synergies with those activities. - Providing a coordinated position for the implementation of innovative solutions in the Technical Specification for Interoperability and safety for the realisation of a "future proof" a Single European Railway Area.

9. THE PREFERRED OPTION - HOW WILL ACTUAL IMPACTS BE MONITORED AND EVALUATED?

9.1. The preferred option

In the table below, the alignment of the preferred option of Institutionalised European Partnership under Article 187 TFEU with the selection criteria for European Partnerships defined in Annex III of the Horizon Europe Regulation is depicted. Seeing that the design process of the candidate Institutionalised European Partnerships is not yet concluded and several of the related topics are still under discussion, the criteria of additionality/directionality and long-term commitment are covered in terms of expectations rather than ex-ante demonstration.

An institutionalised partnership established under Article 187 of TFEU for Transforming Europe's Rail System would meet the requirements set out in *Section 4.4* particularly effectively by:

- Facilitating the development of a strategy that is fully aligned with the completion of SERA, the Green Deal as well as a number of SDGs and the political priorities identified by the President of the Commission;
- Providing a stable framework for encouraging the participation of organisations from different stakeholder groups, also in the context of the post-Covid-19 recovery;

- Developing a system of systems and a coordinated approach to transform the rail sector's system architecture and thereby rail's performance for society;
- Integration of rail innovations in the overall mobility digital eco-system for all modes of transport.
- Leveraging industry financial and in-kind resources such that the impact of funding provided by the Commission is maximised;
- Providing for the effective management of R&I projects, encouraging a high level of market take-up of outputs;
- Facilitating relationships with other partnerships and initiatives within the Climate, Energy and Mobility cluster and other EU initiatives; and
- Enabling timely deployment of innovations with high EU added value through CEF and possibly other instruments, and
- Enabling effective dialogue with national and international standards bodies, Member States and third countries.

General success criteria would include:

- A high market uptake of innovative solutions,
- Increased competitiveness of the rail industry in particular outside Europe, keeping it at the forefront of innovation.
- Increased rail market share, in particular for freight.
- Increased integration of rail operations with other transport modes.
- Creation of jobs.

A number of issues remain open in the definition of the Transforming Europe's Rail System Partnership, notably:

- The budget of the Partnership and, more specifically, the EU funding which will depend on the adoption of the next Multiannual Financial Framework.
- The detailed governance structure, including different categories of members and advisory groups, which is still under discussion with the sector.
- A programme which will be defined in the upcoming stages of the process.
- A specific set of Key Performance Indicators (KPIs) and their related methodology for assessing the achievement of the Partnership's objectives.

Table 15 - Alignment with the selection criteria for European Partnerships

Criterion	Alignment of the preferred option
Higher level of effectiveness	<p>As demonstrated in Chapter 6, an institutionalised partnership would be considerably more effective in improving the competitiveness of both the rail transport industry and RSI and enabling a transformation of the European rail system, since it would ensure that a substantially higher proportion of R&I outputs would be taken up by the market than under other options.</p> <p>The institutionalised partnership would also be effective in meeting the Green Deal objectives and supporting the competitiveness of the European RSI.</p>

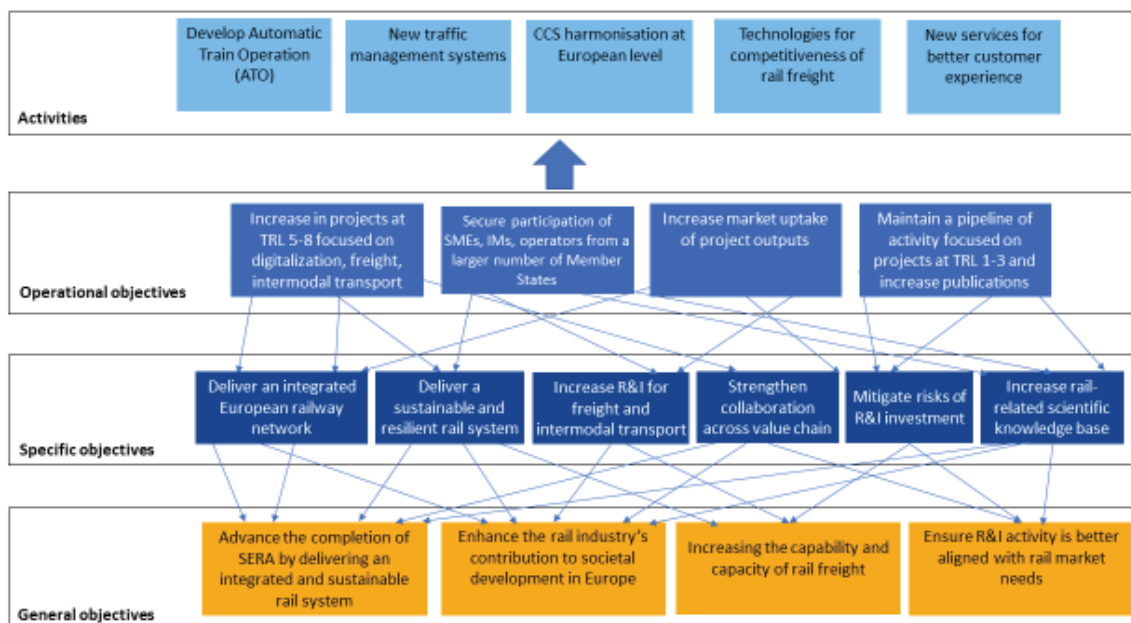

Criterion	Alignment of the preferred option
Coherence and synergies	<p>A dedicated administrative structure responsible for the development of a long-term strategy and supporting work programmes for rail-related R&I would ensure that these were fully integrated with relevant strategies and programmes developed by other partnerships and initiatives. This would enable the better exploitation of synergies from joint programmes and projects, such as ECSEL and 5G for digitalisation and automation, Clean Hydrogen and Batteries as alternative for diesel trains and for autonomous new freight wagon and other transport partnerships concerning interfaces with other modes and multimodality.</p> <p>Thanks to a dedicated deployment manager function, strong coordination with the CEF Programme would help filling the qualitative gap to move from TRL 7 to full deployment, thus addressing one of the main issues faced by the S2R JU.</p>
Transparency and openness	<p>An institutionalised partnership would have more impact in identifying priorities and objectives in terms of expected results and impacts, in involving partners and stakeholders from across the entire rail value chain, from different sectors, backgrounds and disciplines, including SMEs.</p> <p>An institutionalised partnership would be structured around a common, publicly accessible programme providing full transparency regarding the planned objectives and activities, while ensuring comprehensive and balanced representation of the sector (also geographically) and appropriate protection for intellectual property. The framework governing participation would provide for initial calls for members, attaching conditions relating to the provision of funding and a commitment to supporting EU rail policy objectives.</p>
Additionality and directionality	<p>An institutionalised partnership would develop a long-term strategy for rail-related R&I, in consultation with stakeholders inside and outside the rail industry and establish a set of common objectives governing the direction of R&I activity under Horizon Europe. This would be more focused on industry and market needs as well as on the implementation of EU policy objectives than would be the case under other options as well as under the S2R JU.</p> <p>In response to a challenge identified in the interim evaluation of the S2R JU, an institutionalised partnership would be able to set up the appropriate approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level.</p>
Long-term commitments	<p>An institutionalised partnership would also encourage long-term commitment of financial and in-kind resources from infrastructure managers, railway undertakings and other stakeholders (such as SMEs) with access to significant levels of internal funding for R&I activity. Hence, the partnership is expected to ensure a significant share of investment from private sector and other commercial stakeholders.</p>

9.2. Objectives and corresponding monitoring indicators

Several operational objectives have been identified which would enable the partnership to achieve its specific objectives, as shown in Figure 5 below.

The figure also lists a broad range of actions and activities, beyond the R&I activities that can be implemented under Horizon Europe. This reflects the definition of European Partnerships in the Horizon Europe Regulation as initiatives for which the Union and its partners “commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.

Figure 5 - Operational objectives of the initiative

9.2.1. Monitoring indicators

In addition to Key Impact Pathways indicators set centrally in the Regulation of Horizon Europe, additional monitoring indicators have been identified to enable the tracking of progress of the partnership towards meeting its objectives. Data will be collected and processed through a dedicated work stream of the new Partnership, as is currently the case for S2R JU (work on Key Performance Indicators done under Cross Cutting Activities). These are shown in Table 15.

Table 16 - Monitoring indicators in addition to the Horizon Europe key impact pathway indicators

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
Scientific impact – Develop rail-related scientific knowledge base/Deliver scientific results breaking down the current operating limitations/ A strengthened pipeline of potential innovation available to the rail sector	Number of projects resulting in one or more publications	Number of times that publications generated by the partnership are cited in the global literature Number of project outputs taken up in EN standards and TSIs	Number of patents and industrial designs registered by suppliers of railway equipment and systems based in Europe. Project outputs taken up by the market
Scientific impact - A new generation of “rail” engineers and scientists	Number of individuals working on projects initiated by the partnership	Number of occupied and advertised jobs in rail-related R&I	Number of staff transferring between research-based institutions and the rail industry
Technological / economic impact – increase in rail industry direct and indirect	Number of individuals working on projects initiated by the partnership	Level and intensity of rail sector R&I, including new business models	Direct and indirect employment generated by the European rail sector

employment/Creation of new business models and opportunities for the rail stakeholders			
Technological / economic impact – An increase in rail’s modal share of passenger and freight markets	Number of programmed projects at TRLs 1 – 3 with a documented strategy for progressing to TRLs 4 - 7	Number of projects considered to have strong market take-up	Rail’s modal share of passenger and freight transport markets
Technological / economic impact – Creation of significant additional gross added value for the rail sector compared to 2017/Improvement of competitiveness of RSI	Number of programmed projects involving SMEs	Number of projects considered to have strong market take-up	European RSI’s share of global markets
Technological / economic impact – A new rail technological environment	Number of programmed projects developing digital applications	Number of digital projects considered to have strong market take-up	Rail’s modal share of passenger and freight transport markets
Environmental / sustainability impact - Reductions in the environmental impacts of transport	Number of programmed projects developing technological applications	Number of projects considered to have strong market take-up	Reduction of CO ₂ emissions generated by passenger and freight transport Reduction of other emissions (NO _x , noise, etc.)
Social impact - Improvements in the safety, security and health of EU citizens	Number of programmed projects developing safety/security technological applications	Number of relevant projects considered to have strong market take-up	Increased safety and security performance Positive impact on air quality and safety
Social impact - Affordable and accessible mobility and connectivity	Number of programmed projects developing technologies for increased accessibility	Number of relevant projects considered to have strong market take-up	Increased accessibility of rolling stock and stations

9.2.2. Evaluation framework

The evaluation of the Partnership will be done in full accordance with the provisions laid out in Horizon Europe Regulation Article 47 and Annex III, with external interim and ex-post evaluations feeding into the overall Horizon Europe evaluations. As set in the criteria for European Partnerships, the evaluations will include an assessment of the most effective policy intervention mode for any future action; and the positioning of any possible renewal of the Partnership in the overall European Partnerships landscape and its policy priorities. In the absence of renewal, appropriate measures will be developed to ensure phasing-out of Framework Programme funding according to conditions and timeline agreed with the legally committed partners ex-ante.

CONCLUSION

Based on the lessons learned from the S2R Joint Undertaking, it is clear that joint rail research activities coordinated by the EU contribute to a sustainable, punctual, interoperable, high-capacity rail system, providing a backbone for the whole mobility and transport sector in Europe and contributing to the Single European Railway Area. At the same time, the current S2R experience suggests a number of adaptations to make the future partnership even more successful. These include for example a system of systems approach aiming at

transforming rail's system architecture, a more agile governance structure, an increased emphasis on freight, automation and digitalisation and an enhanced focus on deployment of innovative solutions.

The analysis conducted in this Impact Assessment concludes that an Institutionalised Partnership under Article 187 TFEU is the most suitable policy option to develop rail research at the EU level. The stable financial and regulatory framework provided by an Institutionalised Partnership will ensure accessibility to the programme for a wide range of stakeholders, a clear set of objectives in line with the EU policy priorities and a higher level of effectiveness, resulting in increased market uptake. These elements are all the more important, at a time when the rail sector is expected to face a certain level of economic uncertainty, due to the effects of the Covid-19 breakout. Rail research will be key to address present and future challenges of the transport sector and improve mobility of passengers and goods across Europe. In order to achieve the most tangible impact for society, the focus should be on harnessing rail for digital and sustainable transformation of our economy and society.

1. LEAD DG, DECIDE PLANNING REFERENCES

Co-Lead DG: Directorate-General for Mobility and Transport (MOVE), Directorate General Research and Innovation (RTD)

Decide number: PLAN/2019/5398

2. ORGANISATION AND TIMING

Institutionalised partnerships are foreseen in Articles 185 and 187 of the Treaty on the Functioning of the European Union (TFEU). The preliminary agreement on Horizon Europe contained a list of possible areas for institutionalised partnerships based on Article 185 and 187. For each of these areas the Commission considered 12 potential institutionalised partnerships. Their set up involves new EU legislation and the establishment of dedicated implementing structures and therefore an impact assessment for each of these initiatives.

Following political validation in June 2019, the impact assessment process started with the publication of inception impact assessments for each initiative in August 2019.

An inter-service steering group (ISSG) on research and innovation partnerships under Horizon Europe was set up in May 2019 and held 4 meetings before submission of the Staff Working Document to the Regulatory Scrutiny Board (7 May 2019, 19 June 2019, 5 December 2019, 20 January 2020). The ISSG consisted of representatives of the Secretariat-General, Directorate-General for Budget, Directorate-General for Research and Innovation, Directorate-General for Communications Networks, Content and Technology, Directorate-General for Mobility and Transport, Directorate-General for Internal Market, Industry, Entrepreneurship and SMEs, Directorate-General for Energy, Directorate-General for Environment, Directorate-General for Climate Action, and the Legal Service.

An online public stakeholder consultation was launched between September and November 2019, gathering 1635 replies for all 12 initiatives.

3. CONSULTATION OF THE RSB

Two upstream meetings with the Regulatory Scrutiny Board of were held on 10 July 2019 and 30 September 2019.

In accordance with the feedback received from the Regulatory Scrutiny Board on 12.06.2020, the Staff Working Document has been revised as presented in Figure 1. The impact assessment was endorsed by the Inter Service Steering Group on 20.01.2020.

4. EVIDENCE, SOURCES AND QUALITY

To ensure a high level of coherence and comparability of analysis for all candidate initiatives, an external study was procured to feed into the impact assessments of the 12 candidate

institutionalised partnerships¹. It consisted of an horizontal analysis and individual thematic analyses for each of the initiatives under review.

For all initiatives, the evidence used includes desk research partly covering the main impacts and lessons learned from previous partnerships. A range of quantitative and qualitative data sources complement the evidence base, including evaluations; foresight studies; statistical analyses of Framework Programmes application and participation data and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options. Public consultations (open and targeted) supported the comparative assessment of the policy options. For each initiative up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition, the analysis was informed by the results of the Open Public Consultation (Sep – Nov 2019), the consultation of the Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of candidate Institutionalised European Partnerships.

A more detailed description of the methodology and evidence base used, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

Figure 1 Modifications to the draft Staff Working Document based on comments received from the Regulatory Scrutiny Board

Comments from the Regulatory Scrutiny Board	Actions taken for the Staff Working Document
<p>The report should provide more detail on the current partnership, its objectives and its functioning (membership, financing, research focus). It should include more evidence from the evaluation of the partnership and it should better explain how the new partnership will address the weaknesses identified.</p>	<p>More details on the current partnership and the lessons learned from the interim evaluation of S2R JU have been included in Box 2 (Support for the field in the previous Framework Programmes – key strengths & weaknesses identified) in section 3.2 on EU relative positioning in the field. Moreover, an explanation of the leverage generated by S2R JU has been added to section 4.2.2 on the uncoordinated and limited participation in R&I.</p> <p>The differences between the current and future Partnership have been highlighted in section 7.2 (description of the policy options).</p> <p>Explanations on how the future partnership will address the shortcomings of the current</p>

¹ Technopolis Group, 2020, forthcoming.

	<p>one have been added in section 8 on impacts, coherence and tabular comparison of the options.</p>
<p>The report should analyse stakeholder input on the issues of most relevance to the decision on the future partnership. It should differentiate views of stakeholder groups and explain the views of beneficiaries. It should explain how the new partnership would address stakeholders' concerns.</p>	<p>Blue boxes presenting the stakeholder views have been added to sections 4.2.1 (Fragmentation), 4.3 (How the problems will evolve) and 5.1 (5.1. Subsidiarity: Necessity of EU action). Furthermore, the stakeholder views summarised in blue boxes in section 8.1 (Effectiveness) and 8.3 (Coherence) as well as in Annex 1.3 have been revised accordingly, differentiating between various stakeholder groups</p>
<p>The report should better explain the barriers the EU rail sector integration has faced and why the new partnership would be better placed to address these. The report should focus more on how the new partnership would obtain the necessary stakeholder commitment and collaboration from Member States to overcome these barriers. This should include the role and prospects of Member State support for the subsequent uptake of common solutions.</p>	<p>Section 4.2.1 on fragmentation as one of the problem drivers has been thoroughly revised, in order to better present the various aspects related to fragmentation and the related challenges. Moreover, section 6.4.1 on the type and composition of the actors to be involved has been revised accordingly.</p> <p>The specific objectives of the initiative (section 6.2) have been revised in order to make them more operational, and this is reflected now also in the intervention logic.</p> <p>A comparison of possible stakeholders' commitment and Member States collaboration has been added in Table 14, section 8.4 (tabular comparison of the options).</p>
<p>The report should better explain the reasons for the changed focus in the research agenda. It should justify the focus on digitalisation, automation and the freight sector. It should explain how the partnership will achieve the necessary changes in membership to serve the changed focus. Overall, the revised governance structure should be more clearly set out and the role of SMEs in the project clarified.</p>	<p>Section 6.4.2 on the types and activities needed has been revised in order to better explain the changed focus in the research agenda. This is also reflected in the section 6.4.1 on the type and composition of the actors to be involved. Further, with regard to freight, the lessons learnt from the interim evaluation have been expanded (Box 2). A paragraph on freight has been added to section 3.2 (EU relative positioning in the field) and the need for R&I to help freight cope with challenges is now reflected in section 4.3 (on how the problem will evolve).</p> <p>Section 8.4 on the preferred option has been expanded, with additional information,</p>

	<p>referring to more open and transparent processes in the definition of the Programme which will enable wider participation of stakeholders to meet the identified technical and policy objectives. Dedicated paragraphs on the enhanced participation of SMEs and start-ups have been added in section 8.4 on the preferred option and in 6.4.2 on the type and range of activities needed.</p>
<p>The Board notes the estimated costs and benefits of the preferred option in this initiative, as summarised in the attached quantification tables. The table should indicate more clearly who will bear the costs involved.</p>	<p>The EC contribution has been added in the table in Annex 3.2.</p>

Annex 2 Stakeholder Consultation

1. OVERVIEW FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1.1. Introduction

In line with the Better Regulation Guidelines,² the stakeholders were widely consulted as part of the impact assessment process of the 12 candidates for institutionalised partnerships, including national authorities, the EU research community, industry, EU institutions and bodies, and others. These inputs were collected through different channels:

- A feedback phase on the inception impact assessments of the candidate initiatives in August 2019, gathering 350 replies for all 12 initiatives on the “Have your say” web portal during a period of 3 weeks;
- A structured consultation of Member States performed by the EC services over 2019 through the Shadow Strategic Configuration of the Programme Committee of Horizon Europe (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.
- An online public stakeholder consultation administered by the EC, based on a structured questionnaire, open between September and November 2019, gathering 1635 replies for all 12 initiatives;
- A targeted consultation run by the external study contractors with a total of 608 interviews performed as part of the thematic studies by the different study teams between August 2019 and January 2020.

1.2. Horizontal results of the Open Public Consultation

The consultation was open to everyone via the EU Survey online system.³ The survey contained two main parts to collect views on general issues related to European partnerships (in Part 1) and specific responses related to one or more of the 12 candidate initiatives (as selected by a participant). The survey was open from 11 September till 12 November 2019. The consultation was available in English, German and French and advertised widely through the European Commission’s online channels as well as via various stakeholder organisations.

1.2.1. Profile of respondents

In total, 1635 respondents filled in the questionnaire of the open public consultation. Among them, 272 respondents (16.64%) were identified to have responded to the consultation as part of a campaign (coordinated responses). Based on the Better Regulation Guidelines, the groups of respondents where at least 10 respondents provided coordinated answers were labelled as ‘campaigns’, segregated and analysed separately and from other responses. In total 11

² https://ec.europa.eu/info/files/better-regulation-guidelines-stakeholder-consultation_en

³ <https://ec.europa.eu/eusurvey/runner/ConsultationPartnershipsHorizonEurope>

campaigns were identified, the largest of them includes 57 respondents⁴⁴. In addition, 162 respondents in the consultation also display similarities in responses but in groups smaller than 10 respondents. Hence, these respondents were not labelled as campaigns and therefore were not excluded from the general analysis.

Table 1: Country of origin of respondents (N=1635)

Country	Number of respondents	Percentage of respondents
Germany	254	15.54%
Italy	221	13.52%
France	175	10.70%
Spain	173	10.58%
Belgium	140	8.56%
The Netherlands	86	5.26%
Austria; United Kingdom	61	3.73%
Finland	49	3.00%
Sweden	48	2.94%
Poland	45	2.75%
Portugal	32	1.96%
Switzerland	28	1.71%
Czechia	24	1.47%
Greece	23	1.41%
Norway; Romania	22	1.35%
Denmark	20	1.22%
Turkey	19	1.16%
Hungary	14	0.86%
Ireland	12	0.73%
United States	11	0.67%
Estonia; Slovakia; Slovenia	10	0.61%
Bulgaria; Latvia	9	0.55%
Bosnia and Herzegovina	7	0.43%
Lithuania	4	0.24%
Canada; Croatia; Israel	3	0.18%
China; Ghana; Iceland; Japan; Luxembourg; Morocco	2	0.12%
Bhutan; Botswana; Cyprus; Iran; Malta; Mexico; Moldova; Mongolia; Palestine; Russia; Serbia; South Africa; Tunisia; Ukraine; Uruguay	1	0.06%

As shown in Figure 2, the three biggest **categories of respondents** are representatives of companies and business organisations (522 respondents or 31.9%), academic and research institutions (486 respondents or 29.7%) and EU citizens (283 respondents or 17.3%). Among the group of respondents that are part of campaigns, most respondents are provided by the same groups of stakeholders, namely company and business organisations (121 respondents or 44.5%), academic and research institutions (54 respondents or 19.8%) and EU citizens (42 respondents or 15.4%).

⁴⁴ The candidate Institutionalised Partnership Clean Hydrogen has the highest number of campaigns, namely 5. A few initiatives, such as Innovative SMEs, Smart Networks and Systems, were not targeted by campaigns. Some campaign respondents decided to provide opinions about several partnerships.

Figure 2 Type of respondents (N=1635) - For all candidate initiatives

Among all consultation respondents, 1303 (79.69%) have been **involved in the on-going research and innovation framework programme** Horizon 2020 or the preceding Framework Programme 7, while 332 respondents (20.31%) were not. In the group of campaign respondents, the share of those who were involved in these programmes is higher (245 respondents out of 272 or 90.07%) than in the group of non-campaign respondents (1058 out of 1363 or 77.62%). When respondents that participated in the Horizon 2020 or in the preceding Framework Programme 7 were asked to indicate in which capacity they were involved in these programmes, the majority stated they were a beneficiary (1033 respondents) or applicant (852 respondents). The main stakeholder categories, e.g. companies/business organisation, academic/research institutions, etc., show a similar distribution across the capacities in which they ‘have been involved in Horizon 2020 or in the Framework Programme 7’ as the overall population of consultation respondents.

Among those who have been involved in Horizon 2020 or the preceding Framework Programme 7, 1035 respondents (79.43%) are/were **involved in a partnership**. The share of respondents from campaigns that are/were involved in a partnership is higher than for non-campaign respondents, 89.80% versus 77.03% respectively. The list of partnerships under Horizon 2020 or its predecessor Framework Programme 7 together with the numbers, percentages of participants is presented in Table 4, the table also show the key stakeholder categories for each partnership. Most consultation respondents participated in the following partnerships: Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, Clean Sky 2 Joint Undertaking, European Metrology Programme for Innovation and Research (EMPIR) and in Bio-Based Industries Joint Undertaking. The comparison between the non-campaign and campaign groups of respondents shows that the overall distribution is quite similar. However, there are some differences. For the campaign group almost a half of respondents is/was involved in the Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, a higher share of campaign respondents is/was participating in Clean Sky 2 Joint Undertaking and in Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking.

When respondents were asked in which **role(s) they participate(d) in a partnership(s)**, over 40% indicated that they act(ed) as partner/member/beneficiary in a partnership. The second largest group of respondents stated that they applied for funding under a partnership. The roles selected by non-campaign and campaign respondents are similar.

Table 4: Partnerships in which consultation respondents participated (N=1035)

Name of the partnership	Number and % of respondents from both groups (n=1035)	Number and % of respondents from a non-campaign group (n=815)	Academic/research institutions	Business associations	Company/business organisations	Company/business organisations	EU citizens	NGOs	Public authority
Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking	354 (33.33%)	247 (30.31%)	97	9	37	43	41	8	5
Clean Sky 2 Joint Undertaking	195 (18.84%)	145 (17.79%)	57	2	10	27	37	1	7
European Metrology Programme for Innovation and Research (EMPIR)	150 (14.49%)	124 (15.21%)	64	0	13	9	14	2	19
Bio-Based Industries Joint Undertaking	142 (13.72%)	122 (14.97%)	39	8	20	27	14	1	6
Shift2Rail Joint Undertaking	124 (11.98%)	101 (12.40%)	31	7	5	31	14	3	7
Electronic Components and Systems for European Leadership (ECSEL) Joint Undertaking	111 (10.72%)	88 (10.80%)	42	2	7	20	12	0	5
Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking	66 (6.38%)	46 (5.64%)	10	3	3	20	3	2	3
5G (5G PPP)	53 (5.12%)	47 (5.77%)	20	1	6	14	5	0	1
Eurostars-2 (supporting research-performing small and medium-sized enterprises)	44 (4.25%)	40 (4.91%)	17	0	6	1	7	0	6
Innovative Medicines Initiative 2 (IMI2) Joint Undertaking	37 (3.57%)	35 (4.29%)	18	2	3	3	2	4	3
Partnership for Research and Innovation in the Mediterranean Area (PRIMA)	28 (2.71%)	26 (3.19%)	15	0	3	1	2	0	2
European and Developing Countries Clinical Trials Partnership	25 (2.42%)	24 (2.94%)	12	0	1	2	3	3	2
Ambient Assisted Living (AAL 2)	22 (2.13%)	21 (2.58%)	11	2	1	1	3	0	3
European High-Performance Computing Joint Undertaking (EuroHPC)	22 (2.13%)	18 (2.21%)	6	0	2	3	5	0	2

For the remaining of the consultation, respondents could provide their views on each/several of the candidate initiatives. The majority of respondents (31.4%) provided their views on the Clean Hydrogen candidate partnership. More than 45% of respondents from the campaigns selected this partnership. Around 15% provided their views for European Metrology, Clean Aviation and Circular Bio-based Europe. The share of respondents in the campaign group that chose to provide views on the Clean Aviation candidate partnership is of 20%. The smallest number of respondents provided opinions on the candidate initiative ‘EU-Africa research partnership on health security to tackle infectious diseases – Global Health’.

Table 5: Candidate Institutionalised Partnerships for which consultation respondents provide responses (N=1613)

Name of the candidate Institutionalised European partnership	Number and % of respondents from both groups (n=1613)	Number and % of respondents from a non-campaign group (n=1341)
Clean Hydrogen	506 (31.37%)	382 (28.49%)
European Metrology	265 (16.43%)	225 (16.78%)
Clean Aviation	246 (15.25%)	191 (14.24%)
Circular bio-based Europe	242 (15%)	215 (16.03%)
Transforming Europe’s rail system	184 (11.41%)	151 (11.26%)
Key Digital Technologies	182 (11.28%)	162 (12.08%)
Innovative SMEs	111 (6.88%)	110 (8.20%)
Innovative Health Initiative	110 (6.82%)	108 (8.05%)
Smart Networks and Services	109 (6.76%)	107 (7.98%)
Safe and Automated Road Transport	108 (6.70%)	102 (7.61%)
Integrated Air Traffic Management	93 (5.77%)	66 (4.92%)
EU-Africa research partnership on health security to tackle infectious diseases – Global Health	49 (3.04%)	47 (3.50%)

1.2.2. Characteristics of future candidate European Partnerships

Respondents were asked to assess what areas, objectives, aspects need to be in the **focus of the future European Partnerships** under Horizon Europe and to what extent. According to Figure 6, a great number of respondents consider that a significant contribution by the future European Partnerships is ‘fully needed’ to achieve climate-related goals, to the development and effective deployment of technology and to EU global competitiveness in specific sectors/domains. Overall, respondents’ views reflect that many aspects require attention of the Partnerships. The least attention should be paid to responding towards priorities of national, regional R&D strategies, including smart specialisation strategies, according to respondents.

Overall, only minor differences can be found between the main stakeholder categories. Academic/research institutions value the responsiveness towards EU policy objectives and focus on development and effective deployment of technology a little less than other respondents. Business associations, however, find that the future European Partnerships under Horizon Europe should focus a little bit more on the development and effective deployment of

technology than other respondents. Furthermore, business associations, large companies as well as SMEs value the role of the future European Partnerships for significant contributions to EU global competitiveness in specific sectors domains a little higher than other respondents. Finally, both NGOs and Public authorities put a little more emphasis on the role of the future European Partnerships for significant contributions to achieving the UN SDGs. The views of citizens (249, or 18.3%) do not reflect significant differences with other types of respondents. However, respondents that are/were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7 assign a higher importance of the future European Partnerships to be more responsive towards EU policy objectives and to make a significant contribution to achieving the UN’s Sustainable Development Goals.

A qualitative analysis of the “other” answers highlights the importance of collaboration and integration of relevant stakeholders to tackle main societal challenges and to contribute to policy goals against which fragmentation of funding and research efforts across Europe should be avoided. Additionally, several respondents suggested that faster development and testing of technologies, acceleration of industrial innovation projects, science transfer and market uptake are needed. Next to that, many respondents provided answers related to the hydrogen and the energy transition, which corresponds to the high number of respondents that provided answers to the candidate initiative on this topic.

Figure 6: To what extent do you think that the future European Partnerships under Horizon Europe need to (N=1363) (non-campaign replies) For all candidate initiatives

1.2.3. Main advantages and disadvantages of Institutionalised European Partnerships

An open question asked to outline the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe (1551 respondents). The advantages mentioned focus on the development of technology, overall collaboration between industry and research institutions, and the long-term commitment. Disadvantages mentioned are mainly administrative burdens. An overview is provided below.

Advantages mentioned: Long term commitment, stability, and visibility in financial, legal, and strategic terms; Participation of wide range of relevant stakeholders in an ecosystem (large/small business, academics, researchers, experts, etc.); Complementarity with other (policy) initiatives at all levels EU, national, regional; Efficient and effective coordination and management; High leverage of (public) funds; Some innovative field require high levels of international coordination/standardisation (at EU/global level); Ability to scale up technology (in terms of TRL) through collaboration; Networking between members; Direct communication with EU and national authorities

Disadvantages mentioned: Slow processes; System complexity; Continuous openness to new players should be better supported as new participants often bring in new ideas/technologies that are important for innovation; Lower funding percentage compared to regular Horizon Europe projects; Cash contributions; Administrative burdens; Potential for IPR constraints.

1.2.4. Relevance of EU level to address problems in Partnerships' areas

Respondents were asked to rate the **relevance of research and innovation efforts at EU level efforts to address specific problems in the area of partnerships**. Research and innovation related problems were rated as most relevant across all candidate initiatives, followed by structural and resources problems and problems in the uptake of innovations. Overall, all three areas were deemed (very) relevant across the partnerships, as more than 80% of respondents found these challenges (very) relevant. Only minor differences were found between stakeholder categories. Research and innovation problems were found slightly more relevant by academic/research institutions, yet slight less relevant by large companies and SMEs. Structural and resource problems were indicated as slightly more relevant by NGOs, but slightly less by academic/research institutions. While both NGOs and public authorities find slightly more relevant to address problems in uptake of innovation than other respondents. The views of citizens are not differing significantly. Respondents that are/were directly involved in a current/preceding partnership find, however, the need to address problems related to the uptake of innovations slightly more relevant than other respondents.

Figure 9: To what extent do you think this is relevant for research and innovation efforts at EU level to address the following problems in relation to the candidate partnership in question? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.5. Horizon Europe mode of intervention to address problems

Respondents were asked to indicate how these challenges could be addressed through **Horizon Europe intervention**. Just over 50% of all respondents indicated that institutionalised partnerships were the best fitting intervention, with relatively strong differences between stakeholder categories. The use of Institutionalised Partnership was indicated more by business associations and large companies, but less by academic/research institutions and SMEs. While academic/research institutions valued traditional calls more often, this was not the case for business associations, large companies and public authorities. Public authorities indicated a co-programmed intervention more often than other respondents. Citizens indicated slightly less often that institutionalised partnerships were the best fitting intervention. Respondents that are/were directly involved in a current/preceding partnership, selected the institutionalised partnership intervention in far higher numbers (nearly 70%).

Figure 10: In your view, how should the specific challenges described above be addressed through Horizon Europe intervention? (non-campaign replies) For all candidate initiatives

When asked to reflect on their answers, respondents that pointed to the need for using institutionalised partnership mentioned the long-term commitment of collaboration, a common and ambitious R&I strategy as well as the overall collaboration between industry and research institutions. Others shared positive experiences with other modes of interventions:

- Traditional calls, because of their flexibility and integration of a wide range of actors, as long as the evaluation panels do not deviate from the policy focus. This was mentioned by 94 participants, including companies (25), academics (26) and EU citizens (25).
- Co-funded partnership, as a mechanism to ensure that all participants take the effort seriously, while allowing business partnerships to develop. This approach was deemed suitable based on previous experiences with ERANETs. This was raised by 84 participants, 36 of them academic respondents, 18 companies and 16 EU citizens.

- Co-programmed partnerships, to tackle the need to promote and engage more intensively with the private sector. This was mentioned by 97 participants, most of them companies (34), followed by academics (22), business associations (15) and EU citizens (11).

1.2.6. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Setting joint long-term agendas

Respondents were asked how relevant it is for the proposed European Partnerships to meet their objectives to have a strong involvement of specific stakeholder groups in setting joint long-term agenda. All respondents see stakeholders from industry as the most relevant, followed by academia and governments. The involvement of foundations and NGOs as well as other societal stakeholders were, however, still found to be (very) relevant by more than 50% of the respondents. Most respondents indicated the stakeholder group they belong to themselves or that represent them as relevant to involve.

Figure 11: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Setting joint long-term agenda with strong involvement of: (non-campaign replies) For all candidate initiatives

Pooling and leveraging resources through coordination, alignment and integration with stakeholders

Respondents were asked how relevant it is for the proposed European Partnership to meet its objectives to pool and leverage resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with specific groups of stakeholders. Respondents see stakeholders from industry as the most relevant, followed by academia and governments (Member States and Associated Countries). The involvement of foundations and NGOs as well as other societal stakeholders are also still found to be (very) relevant for more than 50% of the respondents. Similarly as described for the question on setting joint long-term agendas, most stakeholder categories valued their own involvement higher than other respondents – although also here differences between stakeholder categories were minor.

Figure 12: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Pooling and leveraging

resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with: (non-campaign replies) For all candidate initiatives

Composition of the partnerships

Regarding the composition of the partnership most respondents indicated that for the proposed European Partnership to meet its objectives the composition of partners needs to be flexible over time and that a broad range of partners, including across disciplines and sectors, should be involved (see Figure 13). When comparing stakeholder groups only minor differences were found. Academic/research institutions and public authorities found the involvement of a broad range of partners and flexibility in the composition of partners over time slightly more relevant than other respondents, while large companies found both less relevant. SMEs mainly found the flexibility in the composition of partners over time less relevant than other respondents, while no significant differences were found regarding the involvement of a broad range of partners. Citizens provided a similar response to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, indicated a slightly lower relevance of the involvement of a broad range of partners and flexibility in the composition of partners over time.

Figure 13: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Partnership composition (non-campaign replies) Aggregation of responses of all candidate initiatives

Implementation of activities

Most respondents indicated that implementing activities like a joint R&I programme, collaborative R&I projects, deployment and piloting activities, providing input to regulatory

aspects and the co-creation of solutions with end-users are all (very) relevant for the partnerships to be able to meet its objectives. Minor differences were found between the main stakeholder categories, the differences found were in line with their profile. As such, academic/research institutions found joint R&I programme & collaborative R&I projects slightly more relevant and deployment and piloting activities, input to regulatory aspects and co-creation with end-users slightly less relevant than other respondents. For SMEs an opposite pattern is shown. Large companies, however, also found collaborative R&I projects slightly more relevant than other respondents, as well as input to regulatory aspects. The views of citizens are similar to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, show a slightly higher relevance across all activities.

Figure 14: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Implementing the following activities (non-campaign replies) For all candidate initiatives

1.2.7. Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Respondents were asked to reflect on the relevance of setting up a legal structure (funding body) for achieving a set of improvements, as shown in the Figure below. In general, 70%-80% of respondents find a legal structure (very) relevant for these activities. It was found most relevant for implementing activities in a more effective way and least relevant for ensuring a better link to practitioners on the ground, however differences are small.

Figure 15: In your view, how relevant is to set up a specific legal structure (funding body) for the candidate European Partnership to achieve the following? (non-campaign replies) Aggregation of responses of all candidate initiatives

When comparing stakeholder categories there are only minor differences. Academic/research institutions indicated a slightly lower relevance for transparency, better links to regulators as well as obtaining the buy-in and long-term commitment of other partners. SMEs also indicated a lower relevance regarding obtaining the buy-in and long-term commitment of other partners. Large companies showed a slightly higher relevance for implementing activities effectively, ensure better links to regulators, obtaining the buy-in and long-term commitment of other partners, synergies with other EU/MS programmes and collaboration with other EU partnerships. NGOs find it slightly more relevant to implement activities faster for sudden market or policy needs. Public authorities, however, find it slightly less relevant to facilitate collaboration with other European Partnerships than other respondents. The views of citizens show a slightly lower relevance for a legal structure in relation to implementing activities in an effective way. Respondents that are/were directly involved in a current/preceding partnership indicated a higher relevance across all elements presented.

1.2.8. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Consulted on the scope and coverage for the partnerships, based on their inception impact assessments, the large majority feels like the scope and coverage initially proposed in the inception impact assessments is correct. However, about 11% to 15% of the respondents indicated the scope and coverage to be too narrow. About 11%-17% of respondents answered “Don’t know”. Overall, differences between the main stakeholder categories were found to be minor. Academic/research institutions indicated slightly more often that the research area was

“too narrow” than other respondents. SMEs on the other hand indicated slightly more often that the research area and the geographical coverage were “too broad”. NGOs and public authorities, however, found the geographical coverage slightly more often “too narrow”. Large companies found the range of activities slightly more often “too broad” and the sectoral focus slightly more often “too narrow” when compared to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership more often indicated that the candidate institutionalised European Partnership have the “right scope & coverage”.

Figure 16: What is your view on the scope and coverage proposed for this candidate institutionalised European Partnership, based on its inception impact assessment? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.9. Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

When asked whether it would be possible to rationalise a specific candidate European Institutionalised Partnership and its activities, and/or to better link with other comparable initiatives, nearly two thirds of respondents answered “Yes” (1000, or 62%), while over one third answered “No” (609, or 39%). Nearly no differences were found between stakeholder categories, only large companies and SMEs indicated slightly more often “Yes” in comparison to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership, indicated “No” more often, the balance is about 50/50 between “Yes” and “No” for this group.

1.2.10. Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Finally, respondents were asked to rate the relevance of partnership specific impacts in three main areas: Societal; Economic/technological; and Scientific impacts. All three areas were deemed (very) relevant across the candidate partnerships. Scientific impact was indicated as the most relevant impact, more than 90% of respondents indicated that this as (very) relevant. Only minor difference between stakeholder groups were found. Academic/research institutions found scientific impacts slightly more relevant, while large companies found economic and technological impacts slightly more relevant than other respondents. NGOs found societal impact slightly more relevant, while SMEs found this slightly less important.

Citizens did not a significantly different view when compared to other respondents. Respondents that are/were directly involved in a current/preceding partnership find all impacts slightly more relevant than other respondents.

Figure 17: In your view, how relevant is it for the candidate European Institutionalised Partnership to deliver on the following impacts? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.3. Stakeholder consultation results for this specific initiative

1.3.1. Scope of the consultation

Transforming Europe's Rail System (TERS) have been identified as one of the Commission's research and innovation initiatives under the Horizon Europe 'Climate, Energy and Mobility' cluster (Pillar II-Cluster 5).

The Commission conducted a series of stakeholder consultations with various stakeholder groups of different levels (e.g. Member States, R&I funding beneficiaries, industry associations, citizens, etc.) to seek views on EU Research and Innovation (R&I), and on the proposed TERS Partnership. In particular, the consultation activities focused on the need for, the scope and coverage, the type and the planned focus of this partnership.

1.3.2. Whom has the Commission consulted

The Commission consulted a wide range of stakeholders (e.g. public authorities, companies, business organisations, academia, research organisations and end-users) to anticipate a broad involvement of interested participants in the partnership. The consultation activities included but were not limited to those which applied for and/or received funding from the current S2R JU. These targeted stakeholders were complemented by the identification of additional relevant stakeholders to be consulted, based on an external study undertaken to feed into the impact assessment for each of the potential institutionalised European Partnerships.

In summary, the following type of stakeholders have been consulted:

- The industrial community, which includes large companies, SMEs and Start-ups, material suppliers and equipment manufacturers;
- The operating community, including railway undertakings and infrastructure managers;
- The research community, consisting of academic/research institutions such as universities, public government-funded organisations, independent organisations or private research centres.
- Public authorities, such as ministries and national bodies for research, EU institutions and bodies.
- EU citizens responding on their own behalf.
- Interested independent authorities and platforms.

1.3.3. How has the Commission consulted?

The Commission launched a structured consultation of Member States through the Shadow Strategic Configuration of the Programme Committee Horizon Europe, which provided early input⁵ into the preparatory work and resulted in 44 possible candidates for European Partnerships, taking into account the identified areas for possible institutionalised partnerships.

⁵ European Partnerships under Horizon Europe: results of the structured consultation of Member States (Report)

In addition, an open public consultation that covered all 12 potential institutionalised partnerships based on Articles 185 and 187 TFEU was launched. This consultation collected input from a broad range of stakeholders, across Europe and associated countries, on both the overall approach and the individual candidates for institutionalised partnerships.

Furthermore, a combination of written consultation tools and direct interactions with stakeholders were put in place, seeking input, views, ideas and experiences. The identified option in the impact assessment largely builds on the outcome of these consultations with stakeholders.

1.3.4. Feedback to the inception impact assessment on candidate initiatives for Institutionalised Partnerships

Following the publication of the inception impact assessment in July 2019, for the initiative “Transforming Europe’s Rail System” 46 individual feedbacks were collected, mainly from companies and business organisations from a significant number of EU Member States.⁶ Among the elements mentioned were:

- The importance of R&I in enhancing the role of rail in an integrated and sustainable European transport system, and the potential for rail to be more competitive through easier planning of multimodal journeys, better management of service disruption and higher quality on-board service;
- The need to reinforce Europe’s technological leadership in rail (an issue highlighted by both business and academic/research organisations);
- The need for EU action to address industry fragmentation currently limiting the level of R&I in the rail sector and the critical need to increase market take-up of new products and services;
- The key role of the rail sector in supporting EU societal objectives, in particular action to limit the impact of climate change;
- Strong endorsement of rail’s potential contribution to broader scientific, technological and economic development across Europe;
- Strong support for an institutionalised partnership capable of developing a long-term strategy for both fundamental research and market-focused innovation in the rail sector.

1.3.5. Structured consultation of the Member States on European partnership

A structured consultation of Member States through the Shadow Strategic Configuration of the Programme Committee Horizon Europe in May/June 2019 provided early input into the preparatory work for the candidate initiatives.

For the initiative “Transforming Europe’s Rail System”, the feedback from countries suggests that the proposed Partnership is to a large extent relevant, with 64% considering it relevant for their national policies and priorities and for their research organisations, including

⁶ Feedback on inception impact assessment to be found on https://ec.europa.eu/info/law/better-regulation/initiatives/ares-2019-4980251/feedback_en?p_id=5722806

universities, and slightly less (61%) consider it very relevant or somewhat relevant for their industry.

Figure 1: Relevance of the European Partnership for Transforming Europe’s rail system in the national context

18 countries reported to have relevant national or regional R&I strategies, plans or programmes in place in support of the proposed Partnership. National economic, sectoral strategies and/or plan with a strong emphasis on research and/or innovation (57%) and R&I strategies or plans (54%) were identified most frequently. Countries reported to a lesser extent to having dedicated R&I funding programmes or instruments (32%) and regional R&I and/or smart specialisation strategies (25%). 5 countries reported other policies/ programmes.

Countries from Central and Eastern Europe stressed the need to focus more on deployment and piloting to transform the results of the partnership into real world solutions, and in this context also to ensure synergies with related policies, and investments at national and EU level (e.g. CEF, Cohesion Funds). Other comments suggested the need to adjust the scope of the proposed partnership and focus more on integrating alternative energy solutions (hydrogen, batteries), digitalisation of the existing system, robotisation for maintenance, ensuring a holistic approach to the railways system including infrastructure and maintenance, and developing user-centred innovations.

The majority of countries (57%) were undecided concerning their interest to participate as partner. 8 countries expressed an interest to join as a partner, and 3 countries expressed no national interest to participate.

The majority of the countries (86%) expressed interest in having access to results produced in the context of the partnership.

Feedback on objectives and impacts

There was good agreement (60%) on the use of partnership approach for Transforming Europe’s Rail System, whilst quarter of respondents remained neutral. The majority of delegations (65%) agreed that the partnership would be effective in achieving the objectives and delivering clear impacts for the EU and its citizens, but to a lesser degree (43%) that it would contribute to improving the coherence and synergies within the EU R&I landscape.

Figure 2: Agreement on arguments for a Partnership for Transforming Europe’s rail system in delivering impacts, improving coherence and synergies

Views on partners, contributions and implementation

Slightly more than half (54%) of the responses agreed on the type and composition of partners, whilst 25% remained neutral and 2 countries disagreed. Additional comments suggest several countries wish to see an increased role of Member States, as well as openness towards new and smaller partners.

Most countries (64%) would need more information on the contributions and level of commitments expected from partners. Additional comments highlight the need to ensure synergies with Cohesion Funds and CEF for exploitation and uptake of innovation.

46% of countries wished for more details to make an informed decision on the proposal to implement the proposed partnership based on the Article 187 TFEU, 36% agree and 18% disagree. It was thus, suggested to analyse whether the objectives of this proposal could be reached with alternative implementation modes, notably the co-programmed model; if not, then countries wish to see a considerable reform in the set-up of the JU. The feedback stressed the need to allocate Union funding through open calls for proposals (subject to comitology).

In addition to the structured consultation, on 25 November 2019, DG MOVE organised a dedicated workshop to discuss mobility partnerships with Member States. During the workshop, Member States expressed the view that additional benefit for countries in participating in partnerships is that it provides access to an extensive network of key research actors and industrial players in the mobility sector to either create or make use of emerging technologies. Moreover, they highlighted the need to ensure better information exchange between partnerships roadmaps and relevant Member State programmes and enable synergies with other EU and national programmes, notably with Cohesion Funds for innovation development and demonstration, and CEF for deployment and market uptake.

1.3.6. Targeted consultation of stakeholders

A targeted consultations with businesses, research organisations and other partners addressed different aspects of the Partnership on Transforming Europe’s rail system.

Table 1: Number of interviews per stakeholder category

Stakeholder category	Number	Share (%)
Associations	9	18%
European body – regulatory agency	1	2%
Freight operators/supply chain	4	8%
Infrastructure manager	5	10%
Member States' transport authorities	4	8%
Passenger operators	7	14%
Research and technologies organisations	5	10%
Research and technology organisation (non-rail)	1	2%
Third party industry suppliers	7	14%
Universities/academic bodies	5	10%
Urban passenger operators	2	4%
TOTAL	50	100%

Key results from the targeted consultation

Objectives

Stakeholders generally indicated that they agree on the S2R JU objectives. There is a consensus that the current objectives remain valid for the future.

Several stakeholders noted the need for stronger deployment efforts, and focus on users. In particular, several interviewees highlighted that inter-modality and door-to-door mobility are key objectives for rail development, and this calls for innovations which are attractive to rail users.

Additional objectives that stakeholders proposed to be included more prominently are:

- Supporting the European rail industry competitiveness in global markets;
- Accelerating innovation deployment; and
- Reducing innovation time to market.

Moreover, some stakeholders (both members and non-members of the S2R JU) proposed a stronger focus on specific themes, in particular:

- Urban rail transport;
- Rail freight transport;
- Rail service level;
- Energy consumption.

Most stakeholders (especially members of S2R JU) indicated that the Joint Undertaking instrument allows better achievement of objectives; the main reasons they reported are:

- Creating an over-reaching picture in rail research, which would not be possible with the Horizon Europe Programme alone and by single research projects;
- Fostering cooperation in the rail sector;
- The legal certainty that the Joint Undertaking brings to members and innovation investors, as a condition for industry players to invest;
- Facilitating technology and operational harmonisation across Europe;
- Accelerating the sector transformation, also to compete on global markets;
- Allowing longer term cooperation among research stakeholders to move to higher TRL levels;
- Being an independent party for business players.

Some stakeholders also highlighted that moving from the current Joint Undertaking cooperation instrument to a co-programmed partnership (or to the Horizon Programme alone) would delay rail research, slow down innovation processes and have negative impacts on the rail industry.

Membership and openness

Generally, members and non-members of S2R JU consider that more flexibility is needed to engage stakeholders based on research needs' development. Several stakeholders proposed the development of mega-projects in which members and non-members cooperate, and which could have flexibility in engaging partners as the projects develop. On the other hand, two stakeholders indicated that bigger projects increase management workload and do not necessarily deliver improved impacts.

Some stakeholders noted that the funding also needs to cover prototypes and industrial projects, and this justifies that more budget needs to be available. Some stakeholders (especially members of S2R JU) noted the geographical imbalance of membership, but also that this reflects the current rail industry geographic balance and the related dominant position of some Member States. They indicated that open calls can enhance more geographical balance. Several interviewees commented that the urban sector is poorly represented in the current member composition, although they noted that it may be constrained by funding from participating into a Joint Undertaking.

Specific stakeholders' proposals on types of members to include, or to include more prominently, are:

- Verification and certification bodies (to ensure that innovations are usable on national rail networks and compatible with interoperability standards);
- National authorities in order to understand the technologies employed locally;
- Infrastructure managers and railway undertakings, to allow more focus on rail operational and service aspects, and to improve the balance of membership between suppliers and users;
- Rail freight nodes (including ports and terminals), which are users of innovation and an important component of logistics chains.

Both members and non-members of S2R JU noted that the rail Partnership should be more open and flexible and that it is difficult for non-members to join through open calls.

With specific reference to the involvement of universities, stakeholders generally indicated that they have an important role in supporting industrial innovation in bringing a long-term perspective to research activities.

A common point for almost all stakeholders, other than rail providers and manufacturers, was the balance between “blue sky research” and research focused on members' priorities. In particular, research stakeholders noted that business players tend to consider innovation in the shorter term, while universities look at innovation on a longer timescale.

Concerning openness, several stakeholders (in particular most of the S2R JU members or other stakeholders engaged in S2R JU activities) indicated that in Shift2Rail, research activities in open call projects are not aligned with the research priority of members. Generally, stakeholders noted that a closer cooperation between members and non-members is needed in the future.

Concerning the partnership dimension, the main suggestion was to increase the number of core members to 15-20 and to engage additional stakeholders on a project or research basis.

Leverage effect

Generally, stakeholders indicated that Shift2Rail has the capacity to leverage private investments and to allow the coordination of investments in risky fields, thanks to the Join Undertaking contractual obligations. Shift2Rail members wished a push to higher TRL and more deployment and market up-take of rail innovations. They also indicated that an important component of this would be that research is accompanied by solid business cases to roll out innovation.

Key Performance Indicators (KPI)

Stakeholders indicated that KPIs refer to the Shift2Rail objectives and are still valid for the future. Suggestions for KPI improvements concerned:

- Defining the baseline values;
- Defining KPI assumptions and framework;
- Defining KPI more specifically;

- Including KPI on:
 - bringing R&I results to the market;
 - regulatory harmonisation issues (e.g. cross-border services with different standards);
 - rail freight transport;
 - rail hubs;
 - data sharing;
 - rail attractiveness to passengers, with reference to satisfaction, experience and comfort; and
 - noise and energy topics.
- Including more focus on coordination with other transport modes and transport decarbonisation.

Costs and benefits

Interviewees indicated the following benefits of the Joint Undertaking cooperation instrument compared to an EU Research & Innovation programme alone or a co-programme partnership:

- More focused calls compared to FP7 and Horizon 2020;
- Long-term vision;
- More visibility compared to other cooperation instruments;
- Legal certainty;
- Reduced fragmentation in research investments/results, avoiding duplication of effort;
- Joint EU approach to solving the rail industry technical problems;
- Wider scale demonstrators and higher TRL;
- Management transparency (compared to projects funded under general Horizon 2020 calls).

On the other hand, interviewees also indicated the following areas of improvement in relation to the current Shift2Rail Joint Undertaking:

- The budget should be higher, and as a consequence many projects have low TRL;
- There could be more flexibility to allocate funding to “blue sky research”;
- The multiannual action plan should be flexible and suited to changes.
- Innovation Programmes should be more connected.
- More visibility of activities and research results across IPs is needed.
- A higher level of cooperation between the EC and Members States is needed.

Critical elements raised by stakeholders concerned:

- The usability of results in the national contexts;

- Confidentiality of project results, which limit their diffusion;
- Limited contribution from some partners of open call projects;
- Implementation of R&I outputs;
- A high degree of bureaucratisation, with complicated rules of cooperation;
- Communication and presentation of research results;

One stakeholder involved in S2 JU activities and projects indicated that project implementation would be better in a co-programmed partnership because member and non-member projects are insufficiently coordinated.

Need for a rail EU partnership

There is a general agreement that an EU partnership for rail is needed in the future. Most stakeholders suggested follow-up of Shift2Rail to complement, continue and deploy previous and ongoing activities and to complete the transformation of the rail sector. Stakeholders mentioned the following advantages of the Shift2Rail Joint Undertaking:

- Shift2Rail brought more clarity than single projects and brought together research and business players.
- European support under Horizon Europe alone would not address the issue of industry fragmentation;
- In the JU, all sector representatives are around the table (EC, Member States, Infrastructure Managers, rail operators, rail suppliers, etc.).
- Other types of partnerships can contribute to generating “silos” in research and isolated groups of stakeholders.
- The JU cooperation instrument is essential to public sector entities, which have specific investment rules requiring a demonstration of investment returns and legal certainty.
- It brings competing companies into R&I cooperation and innovation investment risk sharing.
- The Shift2Rail brand helps selling EU rail R&I results internationally.

Several stakeholders also suggested changes and improvements to the current partnership with reference mainly to openness, membership composition; and integration between call for members and call for non-members.

Research needs

Stakeholders proposed the following priority topics in rail research:

- Digitalisation and digital transformation of the sector;
- IT/augmented reality/digitalisation in signalling and remote control;
- Multimodality and rail last mile integration,;
- Artificial intelligence and robotics for maintenance;

- 5G, data (including Internet of Things), data management and cybersecurity;
- Rail freight terminals, including automatic coupling and single wagon development, supply chain data exchange;
- Automation on mainlines and computer-based controls; Automatic Train Operations;
- Decarbonisation and low carbon technologies;
- Rail capacity improvement;
- New materials (e.g. carbon fibre);
- New methods of maintenance/asset management;
- Noise;
- Safety and security.

Some stakeholders indicated that a stronger partnership between ERRAC and JU is needed. On the other hand, some indicated that the future cooperation instrument could be a light partnership (not a JU) working with ERRAC.

Contribution to EU policies

Stakeholders indicated that the future partnership could focus on:

- Increasing rail efficiency and attractiveness to users to achieve modal shift;
- Promoting the rail sector to policy makers and in particular informing European policies by bringing the industry knowledge, technical evidence and expertise; and
- Projects delivering competitive deployment of products and services.

Governance/organisation

Concerning governance, JU members identified the following main areas of improvement:

- The Governing Board should have more focus on strategic topics.
- The Governing Board is very broad, and the number of members could be reduced.
- The Scientific Committee could be more involved and have more influence, also involving representatives of the industry.

Concerning organisation, different non-members of S2R JU highlighted that a stronger national presence is needed (either in terms of communication or contact points) and that this would allow promoting and marketing research results. Better coordination with Member States was also suggested.

EU added-value

All the stakeholders called for EU action in rail research and innovation. Moreover, some stakeholders indicated that JU is an instrument to support the EU rail industry's competitiveness at global level.

Further benefits of the EU actions that stakeholders indicated were:

- Making funds available;

- Tackling topics (e.g. interoperability, ERTMS) which have an EU dimension and cannot only be tackled at national level;
- Sustaining rail as the greenest transport mode and helping rail to innovate;
- Coordinating rail research to avoid research developing in parallel by single stakeholders or groups of stakeholders (e.g. EU as a catalyst to efficiently deliver rail research), and
- Bringing together competitors in rail innovation (especially in a fragmented sector like rail).

1.3.7. Open Public Consultation

Profile of respondents

151 respondents answered the consultation for the Transforming Europe’s rail system Partnership or part of it. Of these respondents, 32 (21.19%) were citizens. The largest group of respondents were businesses with 62 (41.06%) respondents. There were 29 respondents from academic and research institutions (19.21%) and 14 from business associations (9.27%). 7 respondents were from public authorities (4.64%). The remaining respondents were from NGO’s (2, 1.32%), consumer organisations (1, 0.66%) and other (4, 2.65%). Over two-thirds of respondents, namely 106 (70.20%), have been involved in the on-going research and innovation framework programme, of which 85 respondents (80.19%) were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7.

Needs of future candidate European Partnerships

Figure 3: Views of the respondents in regard to the needs of future European Partnerships under Horizon Europe (N=151)

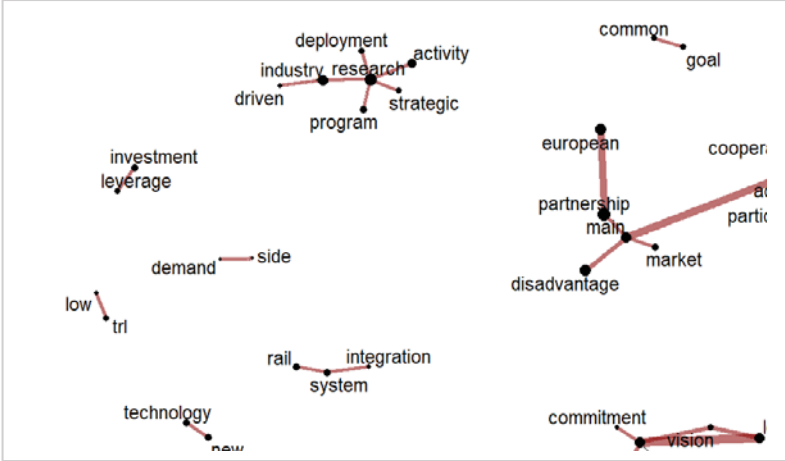

The majority of respondents indicated the need of the future Partnership to make a significant contribution to the EU efforts to achieve climate-related goals (97, 64.24%) and focus more

on the development and effective deployment of technology (95, 62.91%). Both companies and academic institutions highlighted the importance of ensuring the competitiveness of the European rail industry at the global level while focusing on societal objectives and demonstrating the practical benefits of rail-related R&I to a wide audience.

EU citizens identified a range of other needs, including encouraging joint ventures and the participation of SMEs and communicating the key role of the EU in implementing the partnership.

Main advantages and disadvantages of Institutionalised European Partnerships

Figure 4: Assessment of open answers with advantages and disadvantages of participation in an Institutionalised European Partnership, 30 most common co-occurring keywords (N=129)

Companies of all sizes emphasised the advantages of collaboration, including between organisations that compete with one another, and effective coordination of R&I activity. They also identified optimal management of projects, the ability to develop a long-term vision and continuity, stability and visibility of projects as important benefits of participation in an institutionalised partnership.

Academic institutions noted the benefits of building relationships with the rail industry and of pursuing research with practical application to the sector. However, they also noted that some research activities are best conducted in collaboration with a single partner rather than a large number of organisations.

EU citizens highlighted a number of advantages of an institutionalised partnership, including collaborative working to develop a standardised platform for innovation, dedicated funding and the ability to develop a long-term strategy. At the same time, they noted some disadvantages, including the risk of establishing an industry-driven ‘closed shop’ and undue focus on projects with high technology readiness levels (and the associated neglect of more fundamental research).

Relevance of EU level efforts to address problems in relation to the Transforming Europe’s Rail System initiative

Figure 5: Views of respondents on relevance of research and innovation efforts at the EU level to address problems in relation to rail systems

With regard to the uptake in innovation problems, 89 respondents indicated that they view research and innovation efforts at EU level to address the slow deployment and limited market uptake of innovative solutions as very relevant (59.73%). The problem that was viewed as most relevant to be addressed at EU level, was the need to bring together rail research community, supply industry and operators/infrastructure managers, to ensure aligned development and development of innovation.

No statistical differences were found between the views of citizens and other respondents for most problems. Citizens, however, found the research and innovations problem related to the need to strengthen the role of rail in the transport system more relevant and the structural and resource problem related to the fragmentation along the innovation life cycle less.

Horizon Europe mode of intervention to address problems

Figure 6: Assessment of Horizon Europe intervention

Just over 65% of respondents indicated that institutionalised partnerships were the best fitting intervention to address rail challenges and transform the European rail system. People who stated that an institutionalised partnership was the best fitting answer, mentioned the entire product development cycle, long term commitment and market uptake. Respondents who did not select institutionalised partnership as their preferred intervention (N=43) mentioned traditional calls, rail innovation, public and private rail sector and bound funding.

In their open responses, stakeholders gave a number of reasons for supporting an institutionalised partnership as the most effective way of addressing the challenges posed by R&I in the rail sector:

- A number of respondents, including companies, business associations and public authorities, noted that, based on recent experience, only an institutionalised partnership could ensure the level of coordination needed to enable collaboration across a wide range of partner organisations, and that such a partnership would provide the governance and funding framework required to secure their participation.
- EU citizens highlighted the potential for an institutionalised partnership to support the decarbonisation agenda through engagement with national governments and with other EU initiatives focused on exploitation of clean forms of energy.
- However, there was some support for co-financing from at least one academic institution because it would encourage R&I activities focused on the interests of rail users.

Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Figure 7: Views of respondents on relevance of actors in setting a joint long-term agenda

The highest amount of respondents indicated that the involvement of industry is very relevant (123 respondents or 83.11%).

Citizens, as compared to other respondents, found government (Member States and Associated Countries) and foundations and NGOs slightly more relevant. Respondents that are/were involved in a current/preceding partnership (Horizon 2020 or Framework Programme 7) found industry more relevant.

Relevance of elements and activities in pooling and leveraging resources

Figure 8: Views of respondents on relevance of actors for pooling and leveraging resources

With respect to the relevance of actors in pooling and leveraging resources (such as financial, infrastructure, in-kind expertise etc.), to meet Partnership objectives, 113 respondents (76.87%) indicated that industry was very relevant, which is much larger than for any of the other stakeholders. No respondents indicated that any of the categories was not relevant at all. Citizens, as compared to other respondents, found foundations and NGOs slightly more relevant.

Relevance of elements and activities for the partnership composition

Figure 9: Views of respondents on relevance of partnership composition elements

Ensuring involvement of a broad range of partners has slightly more ‘very relevant’ answers (71, 48.30%) than the flexibility in the composition of partners (66, 46.15%). Interestingly 84.62% of respondents have given flexibility either a score of 4 or 5 (very relevant) which is slightly higher than the 83.67% who have given the broad range of partners a score of 4 or 5 (very relevant).

No statistical differences were found between the views of citizens and other respondents.

Relevance of implementation of activities

Figure 10: Views of respondents on relevance of implementation of the following activities

Out of 145 respondents, 106 (73.10%) indicated that deployment and piloting activities and a Joint R&I programme are very relevant to ensure that the Partnership would meet its objectives. For all the other options, the majority (over 50%) of all respondents have indicated that these are very relevant.

No statistical differences were found between the views of citizens and other respondents.

Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Figure 11: Views of respondents on relevance of a specific legal structure

Respondents indicated that it was very relevant to set up a specific legal structure for the partnership to achieve a more effective implementation of activities (91, 62.33%) and to ensure harmonisation of standards and approaches (87, 60.00%).

Respondents involved in a current or preceding partnership found a legal structure more relevant than other respondents when it concerned a faster to response to sudden market or policy needs as well as synergies with other programmes and collaboration with other partnerships.

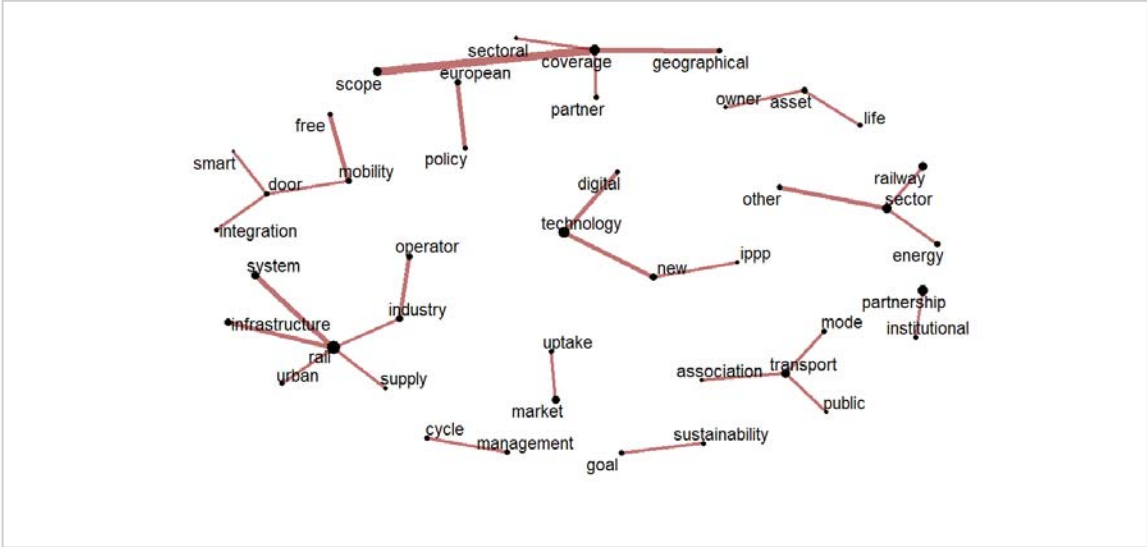

Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Figure 12: Views of respondents on the scope and coverage proposed for the Transforming Europe’s Rail System Partnership

The clear majority of the respondents have indicated that the partnership has the right scope and coverage across all areas. The respondents who have indicated that the scope and coverage are not right, have indicated that it was too narrow more often than they viewed it as too broad.

Figure 13: Assessment of open answers with regard to the proposed scope and coverage for this candidate Institutionalised Partnership, 30 most common co-occurring keywords (N=62)

Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

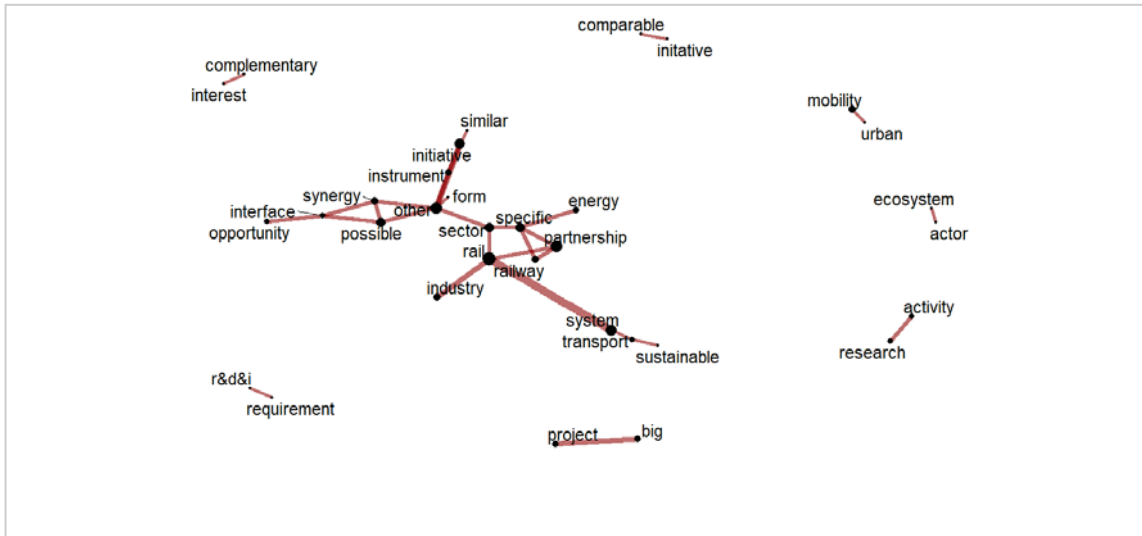

95 respondents (68.84%) indicated that it would be possible to rationalise the candidate European Institutionalised Partnership and its activities, and/or to better link it with other comparable initiatives. Respondents mentioned links with energy mobility and the future of energy as well as digital industry and comparable partnerships and joint undertakings in transport.

Companies were not persuaded that the partnership should be rationalised, however, they supported the case for establishing links with other relevant initiatives, including other partnerships within the Climate, Energy and Mobility Cluster and initiatives focused on sustainability and the development of multi-modal transport solutions.

EU citizens as well as other organisations similarly supported greater coordination of the activities of different initiatives while stopping short of endorsing substantial rationalisation of institutions.

For the respondents who answered negatively on the previous question, the results of the analysis resulted in the chart shown in Figure 14 showing the co-occurrences of keywords. The results show that respondents mention specific partnerships related to energy, railway system and the railway industry as well as comparable initiatives and the possibility of synergy.

Figure 14: Assessment of open answers on the question why other comparable initiatives are not suitable to be linked, 30 most common co-occurring keywords (N=21)

Some respondents argued that both a rationalisation of partnerships and more links with other initiatives would be counter-productive. However, even among respondents expressing doubts about the potential for synergy and links with other initiatives, most indicated that some interaction with partnerships focused on carbon reduction as well as with initiatives concerned with transport would be beneficial.

Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Figure 15: Views of respondents on the relevance of the candidate European Institutionalised Partnership to various impacts

Among presented societal impact categories, a higher number of respondents, namely 121 out of 149 (81.21%), indicated that the Partnership would be ‘very relevant’ for contributing to a cleaner mobility at lower costs, reduced noise, energy consumption and emissions. Among economic/technological impacts, several categories were considered as ‘very relevant’ by around 70% of respondents. In contrast, the lowest number of respondents (namely, 67 and 68 respectively) suggest that the candidate Partnership would have a significant impact on increase of vehicle capacity to support enhanced freight and passenger volume, and on creation of high-quality jobs in the rail sector and in other related sectors. The only listed scientific impact category (“new scientific knowledge and reinforcement of EU scientific capabilities”) received the highest score (5 ‘very relevant’) by 87 out of 149 respondents (58.39%).

No statistical differences were found between the views of citizens and other respondents.

Summary of campaign results

Table 2: Overview of responses of campaign participants (N=29)

Question category	Summary of responses
Research and innovation problems	All answer categories are considered either ‘very relevant’ or ‘relevant’. Among categories, the lowest score was given to “lack of alignment between basic research in rail sector and market needs”.
Structural and resource problems	Most categories are considered either ‘very relevant’ or ‘relevant’ by consultation respondents. The lowest score (on average, 3) is given to the following categories: “deep coordination and alignment of public and private R&I funding” and “uncoordinated programming approach and poor alignment with EU policy goals”.
Problems in uptake of digital innovations	The categories “slow deployment and limited market uptake of innovative solutions” received a high score (either 4 or 5). The other category (“regulatory framework that is not conducive to innovation) received mixed scores – ranging from 2 to 5.
Preferred Horizon Europe intervention	Institutionalised Partnership was selected by all respondents. When respondents were asked to explain their choice, all of them used different versions of the following quote: <i>“Partnership supports bringing together supply Industry, operators, infrastructure managers and research centers and foster long-term commitments of all actors to ensure aligned specifications, development and deployment of innovations. Institutionalised Partnership covers product development cycles, prevents fragmentation among rail ecosystems and accelerates innovations”</i> .
Relevance of actors for setting joint long-term agenda	Most answer categories received an average score (namely, 3) on the scale of 1 to 5. However, industry is considered ‘very relevant’ by the majority of respondents.
Relevance of actors for pooling and leveraging resources	Most answer categories received an average score (namely, 3) on the scale of 1 to 5. However, industry is considered ‘very relevant’ by the majority of respondents.
Partnership composition	Respondents consider the listed elements of partnership composition to be ‘relevant’ (score 4).
Implementation of activities	Almost all respondents rated all listed activities ‘very relevant’.

Question category	Summary of responses
Relevance of the legal structure	<p>Across all categories, respondents indicated that the legal structure would be relevant. Almost all respondents consider that the legal structure would be ‘very relevant’ to implement activities of the Partnership more effectively, to implement activities faster to respond to sudden market or policy needs, to facilitate synergies with other EU and national programmes, to facilitate collaboration with other relevant European Partnerships, and to obtain more buy-in and long-term commitment from other partners.</p>
Scope and coverage of the candidate Partnership	<p>All respondents considered that listed components of the candidate Partnership have right scope and coverage, with the exception of sectoral coverage. In that answer category, almost a third of respondents indicated that the scope and coverage are too narrow.</p> <p>Respondents were offered an opportunity to provide comments on the proposed scope and coverage of the Institutionalised Partnership. All of them included the following quote: <i>“Programme of the rail iPPP shall be aligned with the vision of the rail sector presented: ERRAC 2050 and ERRAC 2030 R&I priorities. Key research areas: Assets for Automatic and Autonomous Operations, Rail Digitalisation, Maintenance of the future (including required equipment), Smart Integration for Door to Door Mobility, Multi-Modality, Environmental Sustainability and Carbon Free Mobility, Rail Freight, Network & Asset Management. Deployment shall also be included to speed up market uptake”</i>.</p>
Rationalisation of the candidate Partnership and linking to other initiatives	<p>The majority of respondents (18, or 64.29%) consider that it would be possible to rationalise the candidate Partnership and its activities, and/or to better link it with other comparable initiatives.</p> <p>Respondents were asked to explain their answer. Regardless of their answer choice, all of them inserted a following quote: <i>“We do not consider possible nor sensible to rationalise further the proposed candidates for Institutionalised Partnerships. The competitiveness and industrial leadership of Europe would be, otherwise, hampered. However, we support ensuring better coordination between the different proposed initiatives. In particular, in the case of rail, coordination with the other initiatives falling within Clusters "Climate, Energy, Mobility" and "Digital, Industry and Space" would be important”</i>.</p>
Societal impact	<p>Majority of respondents considered that the candidate Partnership would be ‘very relevant’ to deliver on the listed societal impact.</p>
Economic/technological impact	<p>Most respondents consider that the candidate Partnership would be “very relevant for the following impacts: “increased competitiveness of the European rail industry on global markets”, “increased economic efficiency of the sector”, “accelerated market uptake of the sector’s scientific and technological developments” and “accelerated transition to digitalisation and enhanced multimodal interfaces”. Other categories, on average, received a score of 4.</p>
Scientific impact	<p>Most respondents consider that the candidate Partnership is ‘very relevant’ and ‘relevant’ for delivering on listed scientific impacts.</p>

1. PRACTICAL IMPLICATIONS OF THE INITIATIVE

The proposed Transforming Europe's Rail System Partnership will focus on a limited number of priorities designed to address emerging challenges of the rail sector, such as automation, digitalisation, decarbonisation and the need to increase the attractiveness of rail freight and its integration into digital multimodal mobility and logistics chains. It will also satisfy Horizon Europe's more demanding societal, economic and technological impact criteria and address the European Union's Green Deal objectives aimed at achieving climate neutrality by 2050. The following stakeholder groups are affected by the proposed initiative, as explained below:

- The private sector, in particular rail suppliers (including SMEs), operators and infrastructure managers, will contribute to the definition of the Programme, making significant commitments for its implementation. The private sector will benefit from a well-defined legal and financial framework, with partners contributing resources in accordance with legally binding requirements relating to the proportion of EU and partner funds, set out in a Council Regulation;
- European universities and research-based organisations will play a pivotal role to increase the scientific knowledge base and contribute to accelerate the development of rail innovations through collaboration with private enterprises;
- Civil society will benefit from the positive impact of rail innovation for passenger and freight transport as well as from the contribution of rail to tackle climate change. The proposed Transforming Europe's Rail System Partnership will enable rail to support the realisation of a people-centred economy in which EU citizens have access to an increasing range of employment, education and leisure opportunities through efficient, attractive and affordable public transport services;
- The support of Member States will be instrumental for the implementation of the programme and the achievement of its objectives (e.g. Green Deal targets). The proposed Transforming Europe's Rail System Partnership will provide a relevant scientific and technology evidence base as well as innovative solutions to make rail a significant part of the solution for the climate challenge and support Member States' efforts to decarbonise transport.

2. SUMMARY OF COSTS AND BENEFITS

<i>I. Overview of Benefits (total for all provisions) – Preferred Option</i>		
<i>Description</i>	<i>Amount</i>	<i>Comments</i>
<i>Direct benefits</i>		
Sustainable cost efficient mobility	Increased attractiveness, accessibility and services for rail passenger and freight through new concepts of operations enabled and system	The increase of the efficiency and reduction of costs will make travelling by rail more accessible to everyone and hence increase its

	integrated approach by breakthrough innovation	social inclusiveness.
More competitive rail industry	The transfer of innovative solutions to the market will boost the competitiveness of European suppliers involved in the partnership. The European rail industry will maintain its market leadership at global level by 2050	Development of solutions with broad support across EU—up to 75% market uptake by 2030
Rail system transformation	Integrated approach enabling the delivery of EU policy objectives and the technical integration of rail innovations in the overall mobility digital eco-system for all modes of transport.	The Partnership will be part of a whole-system approach to investment, cutting across the various interfaces, which recognises the long-lived nature of railway assets.
Indirect benefits		
Transport decarbonisation	Modal shift from more carbon intensive modes to rail will make a significant contribution to transport decarbonisation. In addition, the programme will help further reducing rail's carbon footprint.	Contribution to European Green Deal objectives (e.g. shift substantial part of the 75% of inland freight carried today by road to rail and inland waterways).
Increased quality of life	Increasing rail attractiveness would result in integrated journeys with rail at the core of mobility and transport (high speed, regional and urban, freight) through a climate neutral concept of operations and based on a circular economy system.	This includes the positive impact of reduced emissions (e.g. expected CO2 reduction between 2.5 and 4 million tonnes in 2031).

(1) Estimates are relative to the baseline for the preferred option as a whole (i.e. the impact of individual actions/obligations of the preferred option are aggregated together); (2) Please indicate which stakeholder group is the main recipient of the benefit in the comment section;(3) For reductions in regulatory costs, please describe details as to how the saving arises (e.g. reductions in compliance costs, administrative costs, regulatory charges, enforcement costs, etc.; see section 6 of the attached guidance).

II. Overview of costs – Preferred option							
		Citizens/Consumers		Businesses		Administrations	
		One-off	Recurrent	One-off	Recurrent	One-off	Recurrent
Management/ Administrative costs	Direct costs						Yearly running costs other than Personnel: EUR 1.2 million (baseline 2019 AAR – Title 2) – 50% EC

	Indirect costs						
Personnel costs	Direct costs						Yearly running costs for Personnel: EUR 2.3 million (baseline 2019 AAR – Title 1 – 24 FTE [5 TA + 16 CA + 3 SNEs]) – 50% EC
	Indirect costs						

(1) Estimates to be provided with respect to the baseline; (2) costs are provided for each identifiable action/obligation of the preferred option otherwise for all retained options when no preferred option is specified; (3) If relevant and available, please present information on costs according to the standard typology of costs (compliance costs, regulatory charges, hassle costs, administrative costs, enforcement costs, indirect costs; see section 6 of the attached guidance).

REFIT Cost savings table

Not applicable for the proposed Transforming Europe’s Rail System Partnership. The initiative will benefit from the existing organisation/structure (e.g. the Programme Office) already in place for the S2R 2 JU. There are no additional regulatory costs associated, and no specific simplification measures apply in this case.

Annex 4 Analytical Methods

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines⁷ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This is complemented by integrating the **conditions and selection criteria for European Partnerships**, as well as requirements for setting up Institutionalised Partnerships.⁸

1. OVERVIEW OF THE METHODOLOGIES EMPLOYED

In terms of **methods and evidence used**, the set of impact assessments for all candidate Institutionalised European Partnerships draw on an external study covering all initiatives in parallel to ensure a high level of coherence and comparability of analysis⁹ (Technopolis Group, 2020).

All impact assessment mobilised a mix of qualitative and quantitative data collection and analysis methods. These methods range from desk research and interviews to the analysis of the responses to the Open Consultation, stakeholder analysis and composition/portfolio analysis, bibliometrics/patent analysis and social network analysis, and a cost-effectiveness analysis.

The first step in the impact assessment studies consisted in the definition of the context and the problems that the candidate partnerships are expected to solve in the medium term or long run. The main data source in this respect was desk research. This includes grey and academic literature to identify the main challenges in the scientific and technologic fields and in the economic sectors relevant for the candidate partnerships, as well as the review of official documentations on the policy context for each initiative.

In the assessment of the problems to address, the lessons to be learned from past and ongoing partnerships were taken into account, especially from relevant midterm or ex-post evaluations.

The description of the context of the candidate institutionalised European Partnerships required a good understanding of the corresponding research and innovation systems and their outputs already measured. Data on past and ongoing Horizon 2020 projects, including the ones implemented through Partnerships, served as basis for descriptive statistic of the numbers of projects and their respective levels of funding, the type of organisations participating (e.g. universities, RTOs, large enterprises, SMEs, public administrations, NGOs, etc.) and how the funding was distributed across them. Special attention was given to analysing the participating countries (and groups of countries, such as EU, Associated Countries, EU13 or EU15) and industrial sectors, where relevant. The sectoral analysis required enriching the eCORDA data received from the European Commission services with

⁷ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

⁸ A pivotal element of the present analysis is the so-called two-step 'necessity test' for European Partnerships, used to establish: step 1) the need for a partnership approach in the first place, followed by step 2) a justification for the form of Institutionalised Partnership. The necessity test is described in Annex 6. This impact assessment focuses on the second step of the test.

⁹ Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe

sector information extracted from ORBIS, using the NACE codification up to level 2. These data enabled the identification of the main and, where possible, emerging actors in the relevant systems, i.e. the organisations, countries and sectors that would need to be involved (further) in a new initiative.

A Social Network Analysis was performed by the contractors using the same data. It consisted in mapping the collaboration between the participants in the projects funded under the ongoing R&I partnerships. This analysis revealed which actors – broken down per type of stakeholders or per industrial sector – collaborate the most often together, and those that are therefore the most central to the relevant research and innovation systems.

The data provided finally served a bibliometric analysis run by the contractor aimed at measuring the outputs (patents and scientific publications) of the currently EU-funded research and innovation projects. A complementary analysis of the Scopus data enabled to determine the position and excellence of the European Union on the international scene, and identify who its main competitors are, and whether the European research and innovation is leading, following or lagging behind.

A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options.

The conclusions drawn from the data analysis were confronted to the views of experts and stakeholders collected via three means:

- The comments to the inception impact assessments of the individual candidate institutionalised European Partnerships;
- The open public consultation organised by the European Commission from September to November 2019;
- The interviews (up to 50) conducted by each impact assessment study team conducted between August 2019 and January 2020 (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others).

The views of stakeholders (and experts) were particularly important for determining the basic functionalities (see further below) that the future partnerships need to demonstrate to achieve their objectives as well as their most anticipated scientific, economic and technological, and societal impacts. The interviews allowed more flexibility to ask the respondents to reflect about the different types of European Partnerships. Furthermore, as a method for targeted consultation, it was used to get insights from the actors that both the Study Teams and the European Commission were deemed the most relevant. For the comparative assessment of impacts, the external contractors confronted the outcomes of the different stakeholder consultation exercises to each other with a view of increasing the validity of their conclusions, in line with the principles of triangulation.

Annex 2 includes also the main outcomes of the stakeholder consultation exercises.

2. METHOD FOR ASSESSING THE EFFECTIVENESS, EFFICIENCY AND COHERENCE OF EACH OPTION - THE USE OF FUNCTIONALITIES

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has been adapted to introduce “key functionalities needed” – so as to link the intended objectives of the candidate European Partnerships and what would be crucial to achieve them in terms of implementation. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1 in the main body of the impact assessment). In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options. It also allows for a structured comparison of the options as regards their effectiveness, efficiency and coherence, and also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality).

Figure 3 Overview of key functionalities of each form of implementation of European Partnerships

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
Type and composition of actors (including openness and roles)				
<u>Partners:</u> N.A., no common set of actors that engage in planning and implementation <u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> core of national funding bodies or governmental research organisations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> limited, according to national rules of partner countries	<u>Partners:</u> National funding bodies or governmental research organisation <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations
Type and range of activities (including additionality and level of integration)				
<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions <u>Additionality:</u> no additional activities and investments outside the funded	<u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake <u>Additionality:</u>	<u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
projects <u>Limitations:</u> No systemic approach beyond individual actions	Activities/investments of partners, National funding <u>Limitations:</u> Limited systemic approach beyond individual actions.	<u>Additionality:</u> National funding <u>Limitations:</u> Scale and scope depend on the participating programmes, often smaller in scale	<u>Additionality:</u> National funding	(portfolios of projects, scaling up of results, synergies with other funds. <u>Additionality:</u> Activities/investments of partners/ national funding
Directionality				
<u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years. <u>Limitations:</u> Fully taking into account existing or to be developed SRIA/roadmap	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Input to FP annual work programme drafted by partners, finalised by COM (comitology) Objectives and commitments are set in the contractual arrangement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the Grant Agreement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the legal base.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM (veto-right in governance) Objectives and commitments are set in the legal base.
Coherence: internal (Horizon Europe) and external (other Union programmes, national programmes, industrial strategies)				
<u>Internal:</u> Between different parts of the Annual Work programme can be ensured by COM <u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Limited synergies with other Union programmes and industrial strategies If MS participate, with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with other Union programmes and industrial strategies If MS participate, with national/regional programmes and activities

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made in comparison to the baseline. Therefore, for each of the above criteria, the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. When relevant, this estimation also includes the costs/benefits of discontinuing existing implementation structures. The policy options are then scored compared to the baseline with a + and – system along a two-point

scale, to indicate limited (+ or -) or high (++) or (--) additional/lower performance compared to the baseline. When a policy option is scored 0, this means that its impact is expected to be roughly equal to the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into 'expected impacts' - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the 'key functionalities needed' to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options¹⁰.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU's R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach¹¹ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account¹². The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs

¹⁰ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

¹¹ For further details, see Better Regulation Toolbox # 57.

¹² Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

of each candidate initiative.¹³ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are predominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership the costs of preparation and implementation increase only marginally compared to the baseline (<1%),¹⁴ but lead to an additional R&I investment of at least the same amount than the Union contribution¹⁵ (efficiency of 98% for the overall investment).
- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2,3 times the Union contribution¹⁶. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).¹⁷
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution¹⁸. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution¹⁹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

¹³ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

¹⁴ Specifically, some additional set-up costs linked for example to the creation of a strategic research and innovation agenda (SRIA) and additional running costs linked with the partners role in the creation of the annual work programmes and the Commission's additional supervisory responsibilities. A CPP will have lower overall costs than each of the other types of European Partnership, as it will function with a smaller governance and implementation structure than will be required for a Co-Funded Partnership or an Institutionalised Partnership and – related to this – its calls will be operated through the existing HEU agencies and RDI infrastructure and systems.

¹⁵ Minimum contributions from partners equal to the Union contribution.

¹⁶ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

¹⁷ These costs reflect set-up costs and additional running costs for partners, and the Commission, of the distributed, multi-agency implementation model.

¹⁸ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

¹⁹ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0				↑↑
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0				↑↑
Ex-ante Impact Assessment for partnership		0			↑↑↑
Preparation of EC proposal and negotiation		0			↑↑↑
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0				↑
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC			0		↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**)²⁰. In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

3. METHOD FOR IDENTIFYING THE PREFERRED OPTION – THE SCORECARD ANALYSIS

For the **identification of the preferred option**, a scorecard analysis is used to build a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

This scorecard approach also relies on a standard cost model developed for the external study supporting the impact assessment, as illustrated in **Error! Reference source not found..** These costs essentially refer to the administrative, operational and coordination costs of the

²⁰ More details on the methodology can be found in Annex 4.

various options. The figure shows how the scoring of costs range from a value of 0, in case an option does not entail any additional costs compared to the baseline (traditional calls), to a score of (-) for options introducing limited additional costs relative to the baseline and a score of (- -) when substantial additional costs are expected in comparison with the baseline. Should the costs of a policy option be lower than those of the baseline, (+) and (+ +) are used.

Figure 5: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3: Institutionalised
Administrative, operational and coordination costs	0	(-)	(- -)	(- -)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	0	(-)	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared to baseline; score (- -) = substantial additional costs compared to baseline.

The **baseline (regular calls)** has the lowest administrative, operational and coordination costs. This is based on two facts: firstly, that Horizon Europe traditional calls will not entail any additional one-off costs to be set up or discontinued at the end, where each of the other policy options will require at least some additional set-up and phasing out costs; and secondly, that Horizon Europe will not require any additional running costs, where each of the other policy options will involve additional efforts by the Commission and partners in the carrying out of necessary additional tasks (e.g. preparing annual work programmes).

A **co-programmed partnership** (Option 1 - CPP) will entail slightly higher overall costs as compared with the baseline. There will be some additional set-up costs linked for example with the creation of a strategic research and innovation agenda (SRIA) and additional running costs linked with the partners role in the creation of the annual work programmes and the Commission’s additional supervisory responsibilities. A CPP will have lower overall costs than each of the other types of European Partnership, as it will function with a smaller governance and implementation structure than will be required for a Co-Funded Partnership or an Institutionalised Partnership and – related to this – its calls will be operated through the existing HEU agencies and RDI infrastructure and systems.

The **Co-Funded Partnership** (Option 2 – CFP) has been **scored (- -)** on overall cost. This reflects the additional set-up costs of this policy option and the substantial additional running costs for partners, and the Commission, of the distributed, multi-agency implementation model.

The **Institutionalised Partnership** (Option 3 - IP) has been **scored (- -)** on overall cost. This reflects the substantial additional set-up costs of this policy option – and in particular the high costs associated with preparing the Commission proposal and negotiating that through to a legal document – and the substantial additional running costs for the Commission associated with the supervision of this dedicated implementation model.

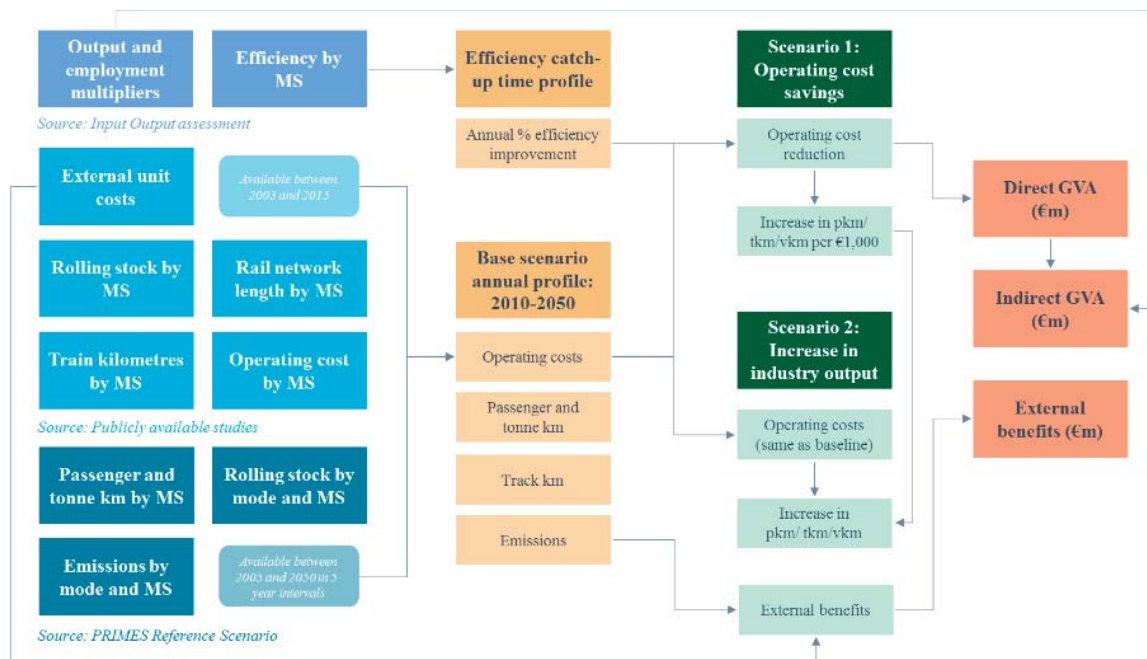

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. A score

of 0 is therefore assigned for **cost-efficiency** to the Co-Programmed option and a score of (-) for the Co-Funded and the Institutionalised Partnership policy options²¹.

4. OVERVIEW OF THE MODELLING FRAMEWORK DEVELOPED FOR THE ASSESSMENT OF IMPACTS OF THE CANDIDATE INSTITUTIONALISED PARTNERSHIPS FOR TRANSFORMING EUROPE'S RAIL SYSTEM

A number of economic/technological impacts have been estimated using a model developed for a 'Study on the Cost and Contribution of the Rail Sector', undertaken by Steer on behalf of the European Commission in 2015. The design of the model is illustrated in the figure below.

Figure 5: Illustration of the modelling framework

Source: Steer

The model uses the following inputs:

- An efficiency score for each of the Member States in the base year and a profile of how efficiency changes over time;
- Metrics measuring the scale of the current network (track kilometres), current operations (train kilometres), current fleet (number of vehicles) and operating costs for each Member State, as well as external cost unit rates; and
- Inputs from the PRIMES Reference Scenario, including activity (passenger and tonne kilometres), fleet composition and emissions for all modes and Member States up to 2050.

As originally specified, the model assesses two different scenarios by Member State:

²¹ The baseline (traditional calls) is scored 0, as explained above.

- One where the Member State railway industry becomes more efficient and the gains in efficiency are fully reflected through savings in operating costs passed on to passengers and freight customers; and
- One where the efficiency gains are fully reinvested in the railway industry, which results in increases in passenger and tonne kilometres.

However, it is possible to adapt the model to investigate the effect of different combinations of transport cost savings and investment.

The model has been used to calculate the external impacts of efficiency gains on traffic levels, mode share, employment and environmental emissions. It can also be used to generate estimates of impact on the economy, measured in terms of Gross Value Added (GVA).

The S2R JU release 2.0 KPI results showing the potential improvement in industry life cycle costs have been used to provide an assumption for the improvement in efficiency under the baseline. The model was then used to estimate the impact of the policy options based on assumptions of further progress towards meeting the KPI target in each case. These assumptions were informed by consideration of both the level of efficiency gains potentially achievable due to R&I activity under each option and the extent of market take-up in each case.

The following table provides an indication of matrix of assumptions used. As described in *Section 6* of the main report, the assumed potential for reductions in life cycle costs were combined with the market take-up value to generate a single value for the assumed efficiency savings to be input into the model.

Table 2: Key efficiency assumptions used in the impact assessment

Option	Potential reduction in life cycle costs by 2030 (assuming 100% market take-up)	Market take-up of R&I outputs	Commentary
Traditional open calls	Passenger: 16.5% reduction Freight: 26% reduction	25 - 33%	Cost reductions indicated by S2RJU KPI release 2.0 (averaged in the case of passenger) – assumed to be captured in baseline. Range of market take-up observed prior to establishment of the S2R JU, as reported by Foster Rail and previous studies.
Co-programmed partnership	Passenger: 25% reduction Freight: 35% reduction	45 - 60%	Assumes some further progress towards targets and a higher rate of market take-up than under the baseline. However, given that several aspects of the problem would persist under the baseline, we have assumed that the improvements are limited.
Article 187 partnership	Passenger: 50% reduction Freight: 50% reduction	50 - 75%	Assumes KPI targets for current JU are met. Market take-up reflects stakeholder views on

			potential under an institutional partnership.
--	--	--	---

Source: Steer review of sources identified in the table

The model was used to generate estimates of changes in traffic levels and modal shift against the baseline on the assumption that 50% of efficiency improvements are passed on to rail passengers and freight customers in the form of, respectively, lower fares and lower freight rates, and that 50% are captured in the form of released funds for additional investment.

1. Can the Union act? What is the legal basis and competence of the Unions' intended action?
1.1 Which article(s) of the Treaty are used to support the legislative proposal or policy initiative?
<p>This proposal is based on (1) Article 185 TFEU which stipulates that in implementing the multiannual framework programme, the Union may make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; and (2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes (both Articles are under Title XIX of the TFEU - Research and Technological Development and Space).</p> <p>The proposal aims to implement Article 8 of the Commission proposal for Horizon Europe - the future EU research and innovation (R&I) programme for 2021-2027, according to which, “<i>European Partnerships shall be established for addressing European or global challenges only in cases where they will more effectively achieve objectives of Horizon Europe than the Union alone and when compared to other forms of support of the Framework programme</i>”. The Horizon Europe proposal has received the political agreement of the Council and the European Parliament.</p>
1.2 Is the Union competence represented by this Treaty article exclusive, shared or supporting in nature?
<p>Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the European Union can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas.</p> <p><i>Subsidiarity does not apply for policy areas where the Union has exclusive competence as defined in Article 3 TFEU²². It is the specific legal basis which determines whether the proposal falls under the subsidiarity control mechanism. Article 4 TFEU²³ sets out the areas where competence is shared between the Union and the Member States. Article 6 TFEU²⁴ sets out the areas for which the Unions has competence only to support the actions of the Member States.</i></p>

²² <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E003&from=EN>

²³ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E004&from=EN>

²⁴ <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:12008E006:EN:HTML>

2. Subsidiarity Principle: Why should the EU act?

2.1 Does the proposal fulfil the procedural requirements of Protocol No. 2²⁵:

- Has there been a wide consultation before proposing the act?
- Is there a detailed statement with qualitative and, where possible, quantitative indicators allowing an appraisal of whether the action can best be achieved at Union level?

This proposal and the accompanying impact assessment were supported by a wide consultation of stakeholders, both during the preparation of the Horizon Europe proposal and - later on, all the candidates for European Partnerships. Member States were consulted via the Shadow Strategic configuration of the Horizon Europe Programme Committee. On candidates for institutionalised Partnerships based on Article 185/187 of the TFEU, an Open Public Consultation (OPC) was held between 11 September and 6 November 2019. Over 1 600 replies were received. In addition, targeted consultation activities were undertaken to prepare the present impact assessment. In particular, for each of the candidate partnerships, an external consultant interviewed a representative sample of stakeholders. The need for EU action as well as its added value were covered in those interviews.

The explanatory memorandum and the impact assessment (horizontal part, Section 3) contain a dedicated section on the principle of subsidiarity, as explained in question 2.2 below.

2.2 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the conformity with the principle of subsidiarity?

The impact assessment accompanying the proposal features a horizontal part on relevant common elements to all the candidate partnerships, including the conformity of the proposed initiative with the principle of subsidiarity (Section 3). Moreover, the individual assessments of each candidate partnership include additional details on subsidiarity, touching in particular on the specificities of a candidate partnership that could not be adequately reflected in the horizontal part of the impact assessment. This will also be reflected in the explanatory memorandum.

2.3 Based on the answers to the questions below, can the objectives of the proposed action be achieved sufficiently by the Member States acting alone (necessity for EU action)?

National action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives, to deliver on the EU's strategic policy priorities (including the climate and energy goals set out in the Paris Agreement, and the European Green Deal), and to contribute to tackling global challenges and meeting the

²⁵ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12016E/PRO/02&from=EN>

Sustainable Development Goals (SDGs).

R&I funded at the national or organisational level, while potentially contributing to the broader development of the European rail system, is unlikely to enable the rail industry to meet European transport and broader policy objectives. Similarly, it is unlikely to ensure the European RSI's ability to compete in international rail product markets against suppliers based in China and other third countries actively building their indigenous rail sector capability, including through major R&I programmes.

(a) Are there significant/appreciable transnational/cross-border aspects to the problems being tackled? Have these been quantified?

The thematic areas covered by the candidate partnerships feature a series of challenges in terms of cross-border/transnational aspects, need to pool resources, need for a critical mass to meet intended policy objectives, need to coordinate different types of actors (e.g. academia, industry, national and regional authorities) across different sectors of the economy and society, which cannot be tackled to the same degree by Member States alone. This is particularly true for the research and innovation (R&I) dimension of the proposed initiative: the importance of a multi-centre and interdisciplinary approach, cross-country data collection and research, and the need to develop and share new knowledge in a timely and coordinated manner to avoid duplication of efforts are key to achieve high quality results and impact. The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide extensive qualitative and quantitative evidence on the above points. In addition, Sections 1 and 2 of the individual impact assessments on the candidate partnerships include more detail on the necessity to act at EU-level in specific thematic areas. Finally, it is worth noting that not all Member States have the same capacity or R&I intensity to act on these challenges. As the desired policy objectives can be fully achieved only if the intended benefits are widespread across the Member States, this requires action at the EU-level.

(b) Would national action or the absence of the EU level action conflict with core objectives of the Treaty²⁶ or significantly damage the interests of other Member States?

As per Article 4(3) TFEU, national action does not conflict with core objectives of the Treaty in the area of R&I. The absence of EU level action in this area would however prevent the achievement of core objectives of the Treaty. Indeed, national action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives on e.g. competitiveness, to deliver on the EU's strategic policy priorities, and to contribute to tackling global challenges and meet the Sustainable Development Goals (SDGs).

(c) To what extent do Member States have the ability or possibility to enact appropriate measures?

As foreseen by Article 4(3) TFEU, this proposal does not hamper Member States' ability to

²⁶ https://europa.eu/european-union/about-eu/eu-in-brief_en

<p>enact appropriate measures in the field of R&I. However, the scale and complexity of the policy objectives pursued by the present initiative cannot be fully addressed by acting at national level alone.</p>
<p>(d) How does the problem and its causes (e.g. negative externalities, spill-over effects) vary across the national, regional and local levels of the EU?</p>
<p>As described in the horizontal part of the impact assessment accompanying the present proposal, several problems (e.g. on competitiveness, global challenges, demographic change) and their underlying causes affect the EU as a whole rather than individual Member States. Where important differences between Member States are present, these are described in Sections 1 and 2 of the individual impact assessments.</p>
<p>(e) Is the problem widespread across the EU or limited to a few Member States?</p>
<p>The problem of coordinating R&I efforts in the thematic areas covered by the candidate partnerships affects all Member States, albeit to different degrees. However, from a general EU perspective, available evidence shows that the EU as a whole needs to step up efforts and investments in thematic areas that are crucial to tackle present and future policy challenges on several fronts, e.g. ageing population, global technological trends, and climate change to name a few. The way these problems affect the EU and its Member States is described in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual impact assessments.</p>
<p>(f) Are Member States overstretched in achieving the objectives of the planned measure?</p>
<p>As indicated in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual assessments, the sheer scale, speed and scope of the needed support to R&I would overstretch national resources, without guaranteeing the achievement of the intended objectives. Acting at EU-level would achieve greater impact in a more effective and efficient manner.</p>
<p>(g) How do the views/preferred courses of action of national, regional and local authorities differ across the EU?</p>
<p>No specific differences between the views of national, regional and local authorities emerged from the stakeholder consultation.</p>
<p>2.4 Based on the answer to the questions below, can the objectives of the proposed action be better achieved at Union level by reason of scale or effects of that action (EU added value)?</p>
<p>EU funded R&I activities, including those covered by the present proposal, produce</p>

demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national initiatives in the same area.

The development of a common European strategy and objectives for rail-related R&I would help to ensure a more coordinated, market-focused approach to R&I activities. It would provide a vehicle for aligning such activity with the EU policy objectives, and for ensuring collaboration among actors from across Europe and along the industry value chain to define projects and programmes designed to address market needs.

(a) Are there clear benefits from EU level action?

Quantitative and qualitative evidence of the benefits of EU level action are available in the interim evaluation of Horizon 2020 and in the impact assessment of Horizon Europe, among others. An analysis of the emerging challenges in each thematic areas, of the EU's competitive positioning, as well as feedback gathered from different types of stakeholders for the present impact assessment indicate that EU level action remains appropriate also for the present proposal. In addition, the benefits of acting at EU-level have been illustrated by the success and the impact achieved by the predecessors to the proposed initiative.

The coordination of R&I at the European level would help to improve the efficiency of the industry in two important ways. First, it would allow pooling of resources available for R&I and their distribution according to a common strategy, thereby reducing the potential for competing and conflicting projects focusing on the needs of national networks and tending to reinforce the geographical fragmentation discussed in the previous chapter. Second, it would encourage the RSI to develop products and systems that further enable the development of a fully integrated European rail system, thereby advancing the creation of a single European market for equipment and allowing them to exploit economies of scale in production more effectively.

(b) Are there economies of scale? Can the objectives be met more efficiently at EU level (larger benefits per unit cost)? Will the functioning of the internal market be improved?

EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. This is the case both in terms of effectiveness in achieving intended policy objectives, but also in terms of efficiency. Positive impact is also visible in terms of competitiveness: recent data on EU funded R&I activities indicate that EU-funded teams grow 11.8% faster and are around 40% more likely to be granted patents or produce patents applications than non-EU funded teams. Efficiency gains are also visible in terms of dissemination of results to users beyond national borders, including SMEs and citizens. EU funded R&I is more effective in leveraging private investment. Finally, there are clear additionality benefits (i.e. EU R&I funding does not displace or replace national funding), as the EU focuses on projects that are unlikely to be funded at national or regional level. Overall, this is beneficial to the functioning of the internal

market in several respects, including human capital reinforcement through mobility and training, the removal of barriers to cross-border activity for economic players including SMEs, easier access to finance and to relevant knowledge and research, and increased competition in the area of R&I.

(c) What are the benefits in replacing different national policies and rules with a more homogenous policy approach?

A homogeneous policy approach in the various thematic areas covered by the present proposal would reduce fragmentation and increase efficiency and effectiveness in meeting the intended policy objectives. Indeed fragmentation, persisting barriers in the internal market and differences in the resources available to Member States are some of the key problems that stand in the way of fully achieving the intended policy objectives and reaching the required critical mass to obtain tangible results. Specific detail on how these issues differ in each thematic area are illustrated in Sections 1 and 2 of the individual impact assessments, so as to reflect the specificities of each case.

(d) Do the benefits of EU-level action outweigh the loss of competence of the Member States and the local and regional authorities (beyond the costs and benefits of acting at national, regional and local levels)?

The proposed initiative does not lead to a loss of competence of the Member States. In fact, the proposed initiative should be seen as complementary and reinforcing national and sub-national initiatives in the same area. Previous quantitative and qualitative assessments of Horizon Europe and Horizon 2020 have shown that the proposed EU-level action do not displace national ones and tend to concentrate on initiatives that would not have been funded by the Member States themselves, or would not have reached the same scale and ambition without EU-level intervention, due to their complexity and trans-national nature.

(e) Will there be improved legal clarity for those having to implement the legislation?

Yes. The proposed initiatives will be implemented in line with the Horizon Europe single set of rules for participation; this will ensure increased clarity and legal certainty for end beneficiaries, other stakeholders and programme administrators. It will also reduce the administrative burden for beneficiaries, and for the Commission services. In addition, the accessibility and attractiveness of the broader Horizon Europe programme, in particular for applicants with limited resources, would be sustained.

3. Proportionality: How the EU should act

3.1 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the proportionality of the proposal and a statement allowing appraisal of the compliance

of the proposal with the principle of proportionality?

The principle of proportionality underpins the entire analysis of the candidate partnerships. Specifically, the analysis included in the accompanying impact assessment is structured along the following logic: 1. Justification of the use of a partnership approach in a given area (including considerations on additionality, directionality, link with strategic priorities) instead of other forms of intervention available under Horizon Europe; 2. If the partnership approach is deemed appropriate, proportionality considerations guide the assessment of which type of partnership intervention (collaborative calls, co-programmed, co-funded or institutionalised partnership) is most effective in achieving the objectives. This will also be reflected in the explanatory memorandum.

3.2 Based on the answers to the questions below and information available from any impact assessment, the explanatory memorandum or other sources, is the proposed action an appropriate way to achieve the intended objectives?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the present proposal leaves full freedom to the Member States to pursue their own actions in the policy areas concerned. This will also be reflected in the explanatory memorandum.

(a) Is the initiative limited to those aspects that Member States cannot achieve satisfactorily on their own, and where the Union can do better?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments.

(b) Is the form of Union action (choice of instrument) justified, as simple as possible, and coherent with the satisfactory achievement of, and ensuring compliance with the objectives pursued (e.g. choice between regulation, (framework) directive, recommendation, or alternative regulatory methods such as co-legislation, etc.)?

For each of the candidate partnerships, the analysis carried out in the accompanying impact assessment has explored several options for implementation. A comparative assessment of the merits of each option also included an analysis of the simplicity of the intervention, its proportionality and effectiveness in achieving the intended objectives. This is reflected in the fact that a tailored approach has been suggested for each candidate partnership, ranging from looser forms of cooperation to more institutionalised ones, depending on the intended policy objectives, specific challenges, and desired outcome identified in each case.

(c) Does the Union action leave as much scope for national decision as possible while achieving satisfactorily the objectives set? (e.g. is it possible to limit the European action to minimum standards or use a less stringent policy instrument or approach?)

The proposed approach leaves full freedom to the Member States to pursue their own actions in the policy areas covered by the present proposal.

(d) Does the initiative create financial or administrative cost for the Union, national governments, regional or local authorities, economic operators or citizens? Are these costs commensurate with the objective to be achieved?

The proposed initiatives do create financial and administrative costs for the Union, national governments and, depending on the chosen mode of implementation, for regional and local authorities. In addition, economic operators and other stakeholders potentially involved in the candidate partnerships will also incur some costs linked to implementation. The financial cost of the proposed initiative is covered under the Horizon Europe programme. Its exact amount is still subject to political decision. As regards the candidate partnerships and the different modes of implementation (co-programmed, co-funded, institutionalised), the relevant costs and benefits are assessed in the individual impact assessments covering each candidate partnership. The additional administrative costs of implementation via partnerships are limited, when compared to the administrative costs of implementation through traditional calls. As indicated by comparable experience with previous initiatives and in feedback provided by a variety of stakeholders, these costs are expected to be fully justified by the benefits expected from the proposed initiative. Where available, additional details on costs are provided in Annex 3 of the impact assessment.

(e) While respecting the Union law, have special circumstances applying in individual Member States been taken into account?

Where relevant, differences between Member States in capacity and stage of advancement of R&I in specific thematic areas have been taken into account in the individual impact assessments.

Annex 6 Additional background information

1. BACKGROUND INFORMATION FOR ALL INITIATIVES

1.1. Selection criteria of European Partnerships

Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

The necessity test for a European Partnership (as set out in the Horizon Europe regulation) has two levels:

1. **The justification for implementing a priority with a European Partnership** to address Horizon Europe and EU priorities. This is linked to demonstrating that a European Partnership can produce added value beyond what can be achieved through other Framework Programme modalities, notably traditional calls in the work programmes (Option 0 – Baseline).
2. **The justification for the use of the form of Institutionalised Partnership:** Once it has been demonstrated that a partnerships approach is justified, co-programmed and/or co-funded forms are considered for addressing the priorities as they are administratively lighter, more agile and easier to set-up (Options 1 and/or 2). As Institutionalised Partnerships require setting up a legal framework and the creation of a dedicated implementation structure, they have to justify higher set-up efforts by demonstrating that it will deliver the expected impacts in a more effective and efficient way, and that a long-term perspective and high degree of integration is required (Option 3).

The outcomes of the ‘necessity test’ is presented together with the preferred option.

Figure 6 Horizon Europe selection criteria for the European Partnerships

Common selection criteria & principles	Specifications
1. More effective (Union added value) clear impacts for the EU and its citizens	Delivering on global challenges and research and innovation objectives
	Securing EU competitiveness
	Securing sustainability
	Contributing to the strengthening of the European Research and Innovation Area
	Where relevant, contributing to international commitments

Common selection criteria & principles	Specifications
2. Coherence and synergies	Within the EU research and innovation landscape
	Coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions
3. Transparency and openness	Identification of priorities and objectives in terms of expected results and impacts
	Involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness
	Clear modalities for promoting participation of smes and for disseminating and exploiting results, notably by smes, including through intermediary organisations
4. Additionality and directionality	Common strategic vision of the purpose of the European Partnership
	Approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level
	Demonstration of expected qualitative and significant quantitative leverage effects, including a method for the measurement of key performance indicators
	Exit-strategy and measures for phasing-out from the Programme
5. Long-term commitment of all the involved parties	A minimum share of public and/or private investments
	In the case of institutionalised European Partnerships, established in accordance with article 185 or 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments

1.2. Overview of potential functions for a common back office among Joint Undertakings

Functions	Current situation	Option of joint back-office	Comments
Organising calls for grant and proposal evaluations	Each JU organises this independently.	A central organisation of evaluation, logistics, contracting evaluators, managing the data of the evaluation results Central database of potential evaluators with domain expertise in thematic areas of partnerships	The evaluations would still need to be supervised by the Scientific staff of the individual Joint Undertakings (consensus meetings of expert evaluators etc)
Human Resources related matters	Each JU has own HR policy and resources Quite some resources spent on recruitment in some JUs	More generic resources and expertise for HR matters More consistency in HR	Ensuring consistency with EC HR policies is already in place

	Some HR facilities are procured from external contractors Some JUs have a Service Level Agreement with COM for HR	policy Shared HR investment for specialised expertise (IP and legal)	
Financial management	Each JU conducts own financial contract management; differences between JUs Each JU is audited separately. Auditing at project level more frequent than in other Horizon 2020 parts and outsourced by JUs thus differences ECA: too many audits on JUs	Financial management by one core team of financial staff Would reduce the number of interfaces for audits and simplifies the auditing of the all JUs Harmonisation of project auditing	Simplifies the harmonisation of financial management across JUs in line with Horizon Europe
Communication (internal and external)	Each JU has a separate communication strategies, teams and resources	A common back-office can support activities such as event organisation, dissemination of results, setting up website communication Can help create a more visible Partnership brand	A considerable share of communication activity is partnership specific (addressing particular target groups, synthesising project results) however there are generic communication activities that can be shared Needs to avoid duplication of efforts
Data management on calls, project portfolios, information on project results	Most JUs but not all use e-Corda for project data Overall IT integration of JUs still difficult	Harmonised data management Reduction of IT systems and support that is procured	This will need to happen regardless of the common back office but will likely be more smooth if managed centrally

2. BACKGROUND INFORMATION FOR THIS SPECIFIC INITIATIVE

General information on current transport policy

In 2011, the Commission published a ‘Roadmap to a Single European Transport Area – towards a competitive and resource efficient transport system’ (the Transport White Paper)²⁷, which set out a series of plans and associated targets for improving the competitiveness, efficiency and sustainability of European transport, removing barriers and bottlenecks in transport infrastructure and addressing societal challenges linked to increasing mobility and connectivity. It described a vision for the European transport network, broadly defined, which included several rail-related goals, in particular:

- A shift of 30% of road freight travelling over 300 km to rail or waterborne transport by 2030, and a shift of more than 50% by 2050, enabled through efficient rail freight corridors and further infrastructure development;
- Completion of the European high-speed rail network by 2050, with most medium-distance passenger transport moving by rail by the same date;
- The delivery of a fully functional, Union-wide and multimodal TEN-T core network by 2030 (with further quality and capacity enhancements completed by 2050);
- Connection of all core airports to rail (preferably high-speed rail) services and connection of all core seaports to rail freight networks by 2050; and
- Deployment of the European Rail Traffic Management System (ERTMS) (among other comparable transport management systems) in accordance with the associated deployment plan.

These goals have set the framework for EU rail policy during the period of Horizon 2020 and have been echoed in the objectives for both the S2R JU and the proposed new partnership for Transforming Europe’s Rail System. The goals are critically dependent on the uptake of technological innovation that can help to deliver a fully integrated railway system for Europe and ensure a step-change in the attractiveness of rail services from the perspective of both passengers and freight customers.

The Fourth Railway Package

The proposal for a new partnership must also be seen in the context of recent rail industry reforms, notably the Fourth Railway Package, which completes the legal framework governing a process of industry restructuring, harmonisation and market opening that began some 30 years ago with Directive 91/440/EEC on the development of the Community’s railways. The Fourth Railway Package is a set of six legislative texts²⁸ designed to implement the final elements of the Single European Railway Area (SERA) with a view to revitalising

²⁷ European Commission (2011), Roadmap to a Single European Transport Area – towards a competitive and resource efficient transport system, 28 March 2011, available at: <https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:52011DC0144&from=EN>.

²⁸ Legislative texts, together with further information on the Fourth Railway Package is available at: https://ec.europa.eu/transport/modes/rail/packages/2013_en

the sector and making it more competitive relative to other transport modes. It is comprised of two pillars:

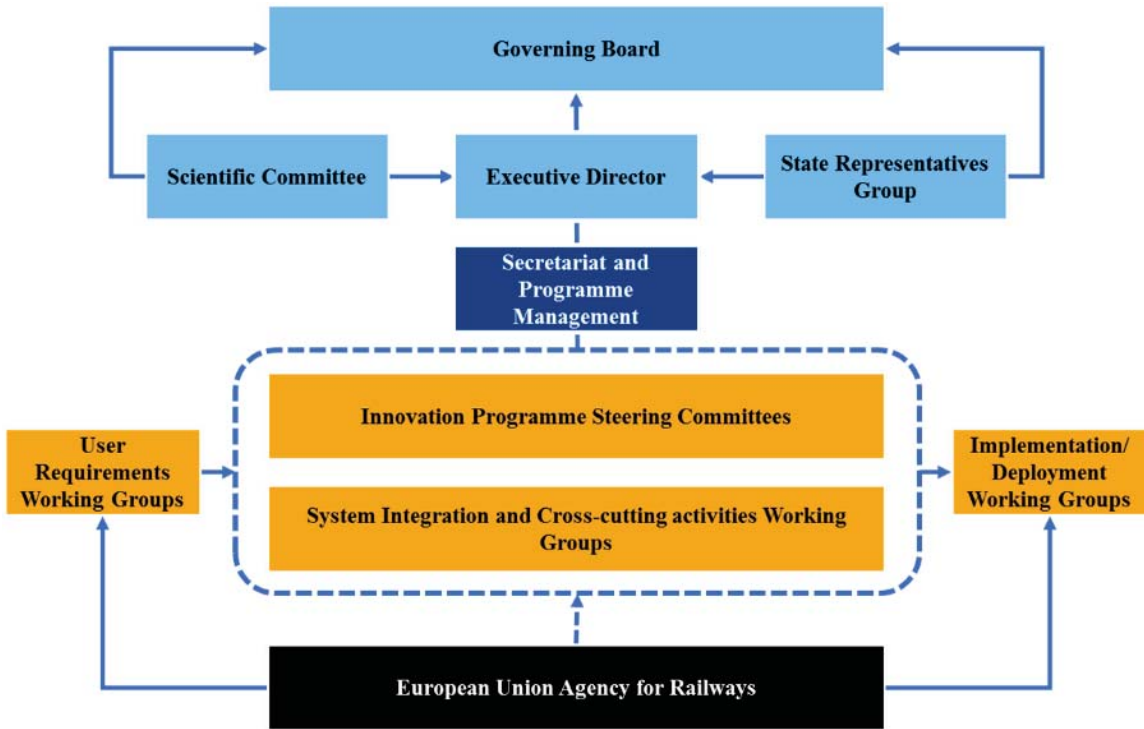

- A technical pillar focusing on a more streamlined, pan-European approach to safety certification and vehicle authorisation, measures to improve interoperability across different national rail networks and an enhanced role for the European Union Agency for Railways (ERA); and
- A market pillar, strengthening previous legislation designed to separate infrastructure management and train operation, providing a more level playing field for rail market access and for greater competitive tendering of public service contracts for rail services.

The implementation of a coordinated R&I effort under Horizon Europe will be complementary to the completion of SERA, since it can be expected to generate opportunities for innovation that can be exploited more effectively in a dynamic rail market environment. At the same time, it will provide a platform for collaboration between different industry players now subject to a greater degree of organisational separation than was previously the case.

The Shift2Rail Joint Undertaking

Organisation and governance

The organisation and governance of the S2R JU are illustrated in the figure below.

Source: Eric Fontanel, Roderick Smith, Heather Allen, Michael Dooms (2017)

As shown, the organisation comprises:

- A Governing Board, including representatives of the founding members, associate members and observers (from ERA and the States Representative Group);
- An Executive Director, supported by a secretariat and programme management department, responsible for oversight of the work programme and day-to-day management of the organisation;
- A series of Steering Committees overseeing each of the five Innovation Programmes (IPs) described below;
- A Scientific Committee and a States Representative Group, providing advice to both the Executive Director and the Governing Board; and
- Various Working Groups considering user requirements, implementation of the outputs of the R&I activity and integration across the IPs as well as various cross-cutting themes.

Innovation programme funding

The R&I activity coordinated by the JU is organised according to a number of innovation programmes (IPs). The table below sets out the budget allocation across IPs expected following adoption of the Annual Work Plan for 2020, as provided to us by the JU. At the time of writing this had not yet been formally approved.

Table 3: S2R JU Innovation Programmes and Cross Cutting Activities

Innovation Programmes/activity	Areas of activity
IP1 – cost-efficient and reliable trains, including high capacity and high-speed trains Budget: €212 M	Train interiors Doors and intelligent access systems Traction Train control and monitoring system Lighter car body shell Running gear Brakes
IP2 – advanced traffic management and control systems Budget: €197 M	Smart, fail-safe communication and positioning systems Traffic management evolution Automation Moving blocks and train integrity Smart procurement and testing Virtual coupling Cyber security
IP3 – cost-efficient, sustainable and reliable high-capacity infrastructure Budget: €153 M	New directions in switch and crossing Innovative track design and materials Cost-effective tunnel and bridge solutions Intelligent system maintenance Improved station concepts Energy efficiency
IP4 – IT solutions for attractive railway services	Technical framework Customer experience applications

Budget: €75 M	Multi-modal travel services
IP5 – Technologies for sustainable attractive European freight Budget: €87 M	Implementation strategies and business analytics Freight electrification, brakes and telematics Access and operation Wagon design Novel terminals, hubs, marshalling yards and sidings New freight propulsion concepts Sustainable rail transport of dangerous goods Long term vision for an autonomous rail freight system
IPX – Disruptive concepts and technologies and system architecture Budget: €20 M	Development of a functional system architecture for the next generation of railway systems
Cross cutting activities	
Total budget: €31 M	Long-term needs and socio-economic research
	Smart materials and processes
	System integration, safety and interoperability
	Energy and sustainability
	Human capital

Contribution to administrative costs

Budget share: €13.5	European Union
Budget share: €13.5	Industry

Source: S2R JU

Contribution to rail sector development

The Council Regulation establishing the JU requires it to meet several objectives that, inter alia, align its activities with the aims of Horizon 2020 and the completion of SERA. The Regulation also sets out key performance indicators (KPIs) that provide a means of measuring its impact on the European rail transport industry. More specifically, the JU is required “to develop, integrate, demonstrate and validate innovative technologies and solutions” that can be measured against the following five KPIs:

- A 50% reduction in the life-cycle costs of the rail system through greater efficiency in the provision of both infrastructure and rolling stock as well as greater energy efficiency;
- A 100% increase in the capacity of the system with a view to accommodating increased demand for both passenger and freight services;

- A 50% increase in the reliability and punctuality of rail services (expressed as a 50% reduction in the percentage of cancellations and late arrivals);
- Removal of the remaining obstacles to interoperability, particularly by closing outstanding open points in the Technical Specifications for Interoperability (TSIs) through the identification of appropriate technological solutions; and
- A reduction in noise, vibration, emissions and other environmental impacts arising from rail transport.

Status of Key Performance Indicators specific for the S2R JU²⁹

#	Key Performance Indicator	Objective	Baseline at the start of H2020	Target at the end of H2020	Automated	Result 2019
1	% reduction in the costs of developing, maintaining, operating and renewing infrastructure and rolling stock and increase energy efficiency compared to "State-of-the-art"	Reduce the life-cycle cost of the railway transport system	"State-of-the-art" 2014	> 50 %	No	See table IV
2	% increase the capacity of railway segments to meet increased demand for passenger and freight railway services compared to "State-of-the-art" 2014	Enhance the capacity of the railway transport system	"State-of-the-art" 2014	100%	No	See table IV
3	% decrease in unreliability and late arrivals compared to "State-of-the-art" 2014	Increase in the quality of rail services	"State-of-the-art" 2014	> 50%	No	See table IV
4	Reduce noise emissions and vibrations linked to rolling stock and respectively infrastructure compared to "State-of-the-art" 2014	Reduce the negative externalities linked to railway transport	"State-of-the-art" 2014	> 3 - 10 dBA	No	-2 dB overall noise limits (FINE1) -4 dB parking operation (FINE1) Specific examples: -6 dB noise damping mechanical absorption solutions (FR8RAIL) -15-20 dB reduced electromagnetic

²⁹ Source: Annual Activity Report 2019

#	Key Performance Indicator	Objective	Baseline at the start of H2020	Target at the end of H2020	Automated	Result 2019
						noise on main transformer (PINTA)
5	Addressing open points in TSIs, compared to "State-of-the-art" 2014	Enhance interoperability of the railway system	"State-of-the-art" 2014		No	One open point of the TSI Infra (tender and IN2TRACK-2)
6	Number of Integrated Technology Demonstrators (ITDs) and System Platform Demonstrations (SPD)	Improve market uptake of innovative railway solutions through large-scale demonstration activities	Multi-Annual Action Plan	4 SPD	No	Updated SPD definition is available (IMPACT-2, deliverable D3.1)
7	Share of the fund allocated to the different Innovation Programmes and to cross-cutting themes	Ensure that funding covers the railway system as a whole	n.a.	> 80%	No	100% of the operational funding
8	Percentage of topics resulting in signature of GA	Ensure a sufficiently high call topics success rate	n.a.	> 90%	Yes	94%
9	% of resources consumption versus plan (members only)	WP execution by members - resources	n.a.	> 80%	Yes	* o/s
10	% of deliverables available versus plan (members only)	WP execution by members - deliverables	n.a.	> 80%	No	- 85.77% (2015-2019) - 81.82% (2019 only)

PART 1 - COMMON FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1. BACKGROUND AND CONTEXT TO EUROPEAN PARTNERSHIPS IN HORIZON EUROPE AND FOCUS OF THE IMPACT ASSESSMENT – WHAT IS DECIDED

1.1. Focus and objectives of the impact assessment

This impact assessment accompanies the Commission proposal for Institutionalised European Partnerships to be funded under Horizon Europe, the 2021-2027 Framework Programme for EU Research and Innovation (R&I).¹ It sets out to **help decide in a coordinated manner the right form of implementation for specific candidate initiatives** based on a common approach and methodology to individual assessments². It also provides an **horizontal perspective on the portfolio of candidate European Partnerships** to identify further efficiency and coherence gains for more impact.

European Partnerships are initiatives where the Union, together with private and/or public partners (such as industry, public bodies or foundations) commit to support jointly the development and implementation of an integrated programme of R&I activities. The rationale for establishing such initiatives is to achieve the objectives of Horizon Europe more effectively than what can be attained by other activities of the programme.³

Based on the Horizon Europe Regulation, European Partnerships may be set up using **three different forms**: “Co-funded”, “Co-programmed” and “Institutionalised”. The setting-up of **Institutionalised Partnerships** involves new EU legislation and the establishment of dedicated implementing structures based on Article 185 or 187 of the Treaty on the Functioning of the EU (TFEU). This requires an impact assessment to be performed.

The Horizon Europe Regulation defines **eight priority areas**, scoping the domains in which Institutionalised Partnerships could be proposed⁴. Across these priority areas, **13 initiatives** have been identified as **suitable candidate initiatives** for Institutionalised Partnerships because of their objectives and scope. This impact assessment aims to identify whether 12 of these initiatives⁵ need to be implemented through this form of implementation and would not deliver equally well with traditional calls of Horizon Europe or other lighter forms of European Partnerships under Horizon Europe. This means assessing whether each of these initiatives meets the necessity test set in the **selection criteria** for European Partnerships in the Horizon Europe Regulation, Annex III.

This assessment is done **without any budgetary consideration**, as the overall budget of the Multiannual Financial Framework of the EU – and hence of Horizon Europe – for the next financing period is not known at this stage.⁶

¹ Horizon Europe Regulation (common understanding), <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

² Based on the European Commission Better Regulation framework (SWD (2017) 350) and supported by an external study coordinated by Technopolis Group (to be published in 2020).

³ For further details on these points, see below Section 1.2.2.

⁴ Set out in the Annex Va of the Horizon Europe Regulation (common understanding). <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

⁵ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47).

⁶ EU budget commitments to the European Partnership candidates can only be discussed and decided following the political agreement on the overall Multiannual Financial Framework and Horizon Europe budgetary envelopes. The level of EU contribution for individual partnerships should be determined once there are agreed objectives, and clear commitments from

1.2. The political and legal context

1.2.1. Shift in EU priorities and Horizon Europe framework

European priorities have evolved in the last decades, and reflect the social, economic, and environmental challenges for the EU in the face of global developments. In her Political Guidelines for the new European Commission 2019 – 2024⁷, the new Commission President put forward six overarching priorities, which reach well beyond 2024 in scope⁸. Together with the Sustainable Development Goals (SDGs), these priorities will shape future EU policy responses to the challenges Europe faces, and thus also give direction to EU research and innovation.

As part of the Multi-annual Financial Framework (MFF) 2021-27 the new EU Framework Programme for Research and Innovation **Horizon Europe will play a pivotal role for Europe to lead the social, economic, and environmental transitions needed to achieve these European policy priorities**. It will be more impact driven with a strong focus on delivering European added value, but also be more effective and efficient in its implementation.⁹ Horizon Europe finds its rationale in the daunting challenges that the EU is facing, which call for “*a radical new approach to developing and deploying new technologies and innovative solutions for citizens and the planet on a scale and at a speed never achieved before, and to adapting our policy and economic framework to turn global threats into new opportunities for our society and economy, citizens and businesses.*” While Horizon Europe continues the efforts of strengthening the scientific and technological bases of the Union and foster competitiveness, a more strategic and impact-based approach to EU R&I investment is taken. Consequently, the **objectives of Horizon Europe** highlight the need *to deliver on the Union strategic priorities and contribute to the realisation of EU objectives and policies, contribute to tackling global challenges, including the Sustainable Development Goals by following the principles of the Agenda 2030 and the Paris Agreement.*¹⁰

In this context, **at least 35 % of the expenditure from actions under the Horizon Europe Programme will have to contribute to climate action**. Furthermore, a **Strategic Plan** is co-designed with stakeholders to identify **key strategic orientations for R&I support** for 2021-2024 in line with the EU priorities. In the Orientations towards the first Strategic Plan for Horizon Europe, the need to strategically prioritise and “*direct a substantial part of the funds towards the areas where we believe they will matter the most*” is emphasised. The Orientations specify, that actions under Pillar II of Horizon Europe “Global Challenges and European Industrial Competitiveness” will target only selected themes of especially high impact that significantly contribute to delivering on the political priorities of the Union. Most of the candidate European Partnerships fall under this Pillar.

1.2.2. Key evolutions in the approach to partnerships in Horizon Europe

Since their start in 1984 the successive set of Framework Programmes uses a variety of instruments and approaches to support R&I activities, address global challenges and industrial

partners. Importantly, there is a ceiling to the partnership budgets in Pillar II of Horizon Europe (the legal proposal specifies that *the majority of the budget in pillar II shall be allocated to actions outside of European Partnerships*).

⁷ https://ec.europa.eu/info/strategy/priorities-2019-2024_en

⁸ 1.A European Green Deal; An economy that works for people; A Europe fit for the Digital Age; Promoting our European way of life; A Stronger Europe in the World; and 6.A New push for European Democracy

¹⁰ Article 3, Common understanding regarding the proposal for Horizon Europe Framework Programme.

competitiveness. Collaborative, competition-based and excellence-driven R&I projects funded through Work Programmes are the most traditional and long-standing approach for implementation. Since 2002, available tools also include **partnerships**, whereby the Union together with private and/or public partners commit to jointly support the development and implementation of a R&I programme. These were introduced as part of creating the European Research Area (ERA) to align national strategies and overcome fragmentation of research effort towards an increased scientific, managerial and financial integration of European research and innovation. Interoperable and integrated national research systems would allow for better flows of knowledge, technology and people. Since then, the core activities of the partnerships consist of building critical mass mainly through collaborative projects, jointly developing visions, and setting strategic agendas.

As analysed in the **interim evaluation of Horizon 2020**¹¹, a considerable repertoire of partnership initiatives have been introduced over time, with 8 forms of implementation¹² and close to 120 partnership initiatives running under Horizon 2020 - without clear exit strategies and concerns about their degree of coherence, openness and transparency. Even if it is recognised that these initiatives allow setting long-term agendas, structuring R&I cooperation between otherwise dispersed actors, and leveraging additional investments, the evaluation points to the complexity generated by the proliferation of instruments and initiatives, and their insufficient contribution to policies at EU and national level.

Box 1 Key lessons from the interim evaluation of Horizon 2020 and R&I partnerships

- The **Horizon 2020 Interim Evaluation** concludes that the overall partnership landscape has become overly complex and fragmented. It identifies the need for rationalisation, improve their openness and transparency, and link them with future EU R&I missions and strategic priorities.
- The **Article 185 evaluation** finds that these public-public partnerships have scientific quality, global visibility and networking/structuring effects, but should in the future focus more on the achievement of policy impacts. From a systemic point of view, it found that the EU public-to-public cooperation (P2P) landscape has become crowded, with insufficient coherence.
- The **Article 187 evaluation** points out that Public-Private Partnership (PPP) activities need to be brought more in line with EU, national and regional policies, and calls for a revision of the Key Performance Indicators. As regards the **contractual PPPs (cPPPs)** their reviews identified challenges of coherence among cPPPs and the need to develop collaborations and synergies with other relevant initiatives and programmes at EU, national and regional level.

Over 80% of respondents to the Open Public Consultation (OPC) indicated that a significant contribution by future European Partnerships is 'fully needed' to achieve climate-related goals, to develop and effectively deploy technology, and for EU global competitiveness in specific sectors/domains. Views converged across all categories of respondents, including citizens, industry and academia.

¹¹ Interim evaluation of Horizon 2020, Commission Staff Working Document, SWD(2017)221 and 222 Interim evaluation of the Joint Undertakings operating under Horizon 2020 (Commission Staff Working Document, SWD(2017) 339); Evaluation of the Participation of the EU in research and development programmes undertaken by several Member States based on Article 185 of the TFEU, Commission Staff Working Document, SWD (2017)340

¹² E.g. initiatives based on Article 187 (Joint Technology Initiatives), Article 185 TFEU, Contractual Public-Private Partnerships (cPPPs), Knowledge & Innovation Communities of the European Institute of Innovation & Technology (EIT-KICs), ERA-NETs, European Joint Programmes, Joint Programming Initiatives.

The impact assessment of Horizon Europe identifies therefore the need to **rationalise the EU R&I funding landscape**, in particular with respect to partnerships, as well as to **re-orient partnerships towards more impact** and delivery on EU priorities. To address these concerns and to realise the higher ambition for European investments, Horizon Europe puts forward a **major simplification and reform for the Commission’s policy on R&I partnerships**¹³. Reflecting its pronounced systemic nature aimed at contributing to EU-wide ‘transformations’ towards the sustainability objectives, Horizon Europe indeed intends to make a more effective use of these partnerships with a **more strategic, coherent and impact-driven approach**. Key related changes that apply to all forms of European Partnerships encapsulated in Horizon Regulation are summarised in the Box below.

Box 2 Key features of the revised policy approach to R&I partnerships under Horizon Europe based on its impact assessment

- ✓ **Simpler architecture & toolbox** by streamlining 8 partnership instruments into 3 implementation forms (Co-Funded, Co-Programmed, Institutionalised), under the umbrella ‘European Partnerships’
- ✓ **More systematic and transparent approach** to selecting, implementing, monitoring, evaluating and phasing out all forms of partnerships (**criteria** for European Partnerships):
 - The selection of Partnerships is embedded in the strategic planning of Horizon Europe, thereby ensuring coherence with the EU priorities. The selection criteria require that partnerships are established with stronger ex-ante commitment and higher ambition.
 - The implementation criteria stipulate that initiatives adopt a systemic approach in achieving impacts, including broad engagement of stakeholders in agenda-setting and synergies with other relevant initiatives to promote the take-up of R&I results.
 - A harmonised monitoring & evaluation system will be implemented, and ensures that progress is analysed in the wider context of achieving Horizon Europe objectives and EU priorities.
 - All partnerships need to develop an exit strategy from Framework Programme funding. This new approach is underpinned by principles of openness, coherence and EU added value.
- ✓ **Reinforced impact orientation:**
 - Partnerships are established only if there is evidence they support achieving EU policy objectives more effectively than other Horizon Europe actions, by demonstrating a clear vision and targets (**directionality**) and corresponding long-term commitments from partners (**additionality**).
 - European Partnerships are expected to provide mechanisms – based on a concrete roadmap - to join up R&I efforts between a broad range of actors towards the development and uptake of innovative solutions in line with EU priorities, serving the economy and society, as well as scientific progress.
 - They are expected to develop close synergies with national and regional initiatives, acting as dynamic change agents, strengthening linkages within their respective ecosystems and along the value chains, as well as pooling resources and efforts towards the common EU objectives.

Under Horizon Europe, a ‘European Partnership’¹⁴ is defined as *“an initiative where the Union, prepared with early involvement of Member States and/or Associated Countries, together with private and/or public partners (such as industry, universities, research organisations, bodies with a public service mission at local, regional, national or international level or civil society organisations including foundations and NGOs), commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”*

The Regulation further specifies that European Partnerships shall adhere to the *“principles of Union added value, transparency, openness, impact within and for Europe, strong leverage effect on sufficient scale, long-term commitments of all the involved parties, flexibility in implementation, coherence, coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions.”*

¹³ Impact assessment of Horizon Europe, Commission Staff Working Document, SWD(2018)307.

¹⁴ Article 8 and Annex III of the Horizon Europe Regulation (common understanding)

1.3. Why should the EU act

1.3.1. Legal basis

Proposals for Institutionalised European Partnerships are based on:

- 1) Article 185 TFEU which allows the Union to make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; or
- 2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes.¹⁵

1.3.2. Subsidiarity

The EU should act only in areas where there is demonstrable advantage that the action at EU level is more effective than action taken at national, regional or local level. Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the EU can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas. The candidate initiatives focus on areas where there is a demonstrable value added in acting at the EU level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national activities in the same area. Overall European Partnerships find their **rationale in addressing a set of systemic failures**¹⁶:

- Their primary function is to create a platform for a strengthened **collaboration** and knowledge exchange between various actors in the European R&I system and an enhanced **coordination** of strategic research agendas and/or R&I funding programmes. They aim to address **transformational failures** to better align agendas and policies of public and private funders, pool available resources, create critical mass, avoid unnecessary duplication of efforts, and leverage sufficiently large investments where needed but hardly achievable by single countries.
- The concentration of efforts and pooling of knowledge on common priorities to solve multi-faceted societal and economic challenges is at the core of these initiatives. Specifically, enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems are among the key objectives of these instruments. In the light of Horizon Europe, the aim is to **drive system transitions and transformations towards EU priorities**.
- Especially in fast-growing technologies and sectors such as ICT, there is a need to **react to emerging opportunities** and address systemic failures such as shortage in skills or critical mass or cross-sectoral cooperation along the value chains that would hamper attainment of future European leadership and/or strategic autonomy.
- They also aim to address **market failures** predominantly to enhancing industry investments thanks to the sharing of risks.

¹⁵ Both Articles are under Title XIX of the TFEU - Research and Technological Development and Space.

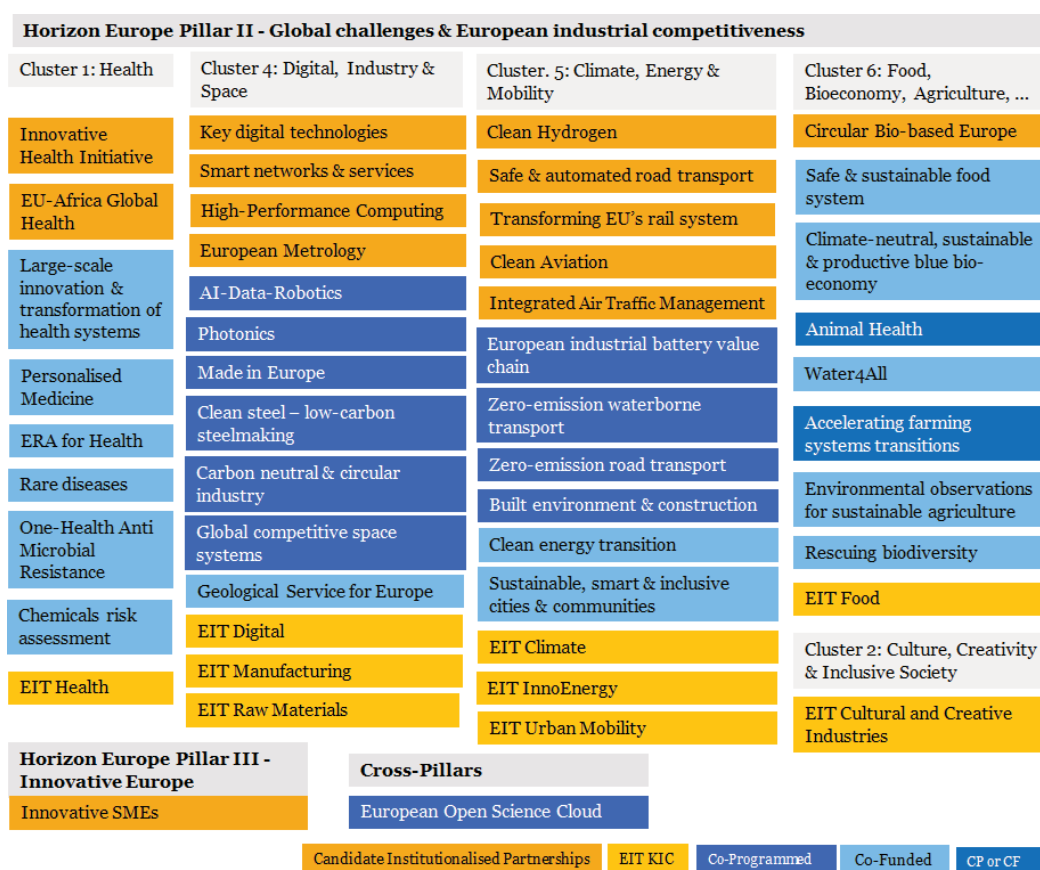

¹⁶ The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide qualitative and quantitative evidence on these points. Sections 1 and 2 of each impact assessment on candidate European Partnerships include more detail on the necessity to act at EU level in specific thematic areas.

2. THE CANDIDATE EUROPEAN PARTNERSHIPS – WHAT NEEDS TO BE DECIDED

2.1. Portfolio of candidates for Institutionalised European Partnerships

The new approach for more objective-driven and impactful European Partnerships is reflected in the way candidate Partnerships have been identified. It involved a co-design exercise aiming to better align these initiatives with societal needs and policy priorities, while broadening the range of actors involved. Taking into account the 8 areas for Institutionalised European Partnerships set out in the Horizon Europe Regulation¹⁷, a co-design exercise as part of the Strategic Planning process of Horizon Europe lead to the identification of **49 candidates for Co-funded, Co-programmed or Institutionalised European Partnerships**¹⁸. Out of these, **13 were identified as suitable candidate Institutionalised Partnerships because of their objectives and scope**¹⁹. Whilst the Co-Funded and Co-Programmed Partnerships are linked to the comitology procedure (including the adoption of the Strategic Plan and the Horizon Europe Work Programmes), Institutionalised Partnerships require the adoption of legislation and are subject to an impact assessment. The Figure below gives an overview of all candidate European Partnerships according to their primary relevance to Commission priorities for 2019-2024.

Figure 1 - Overview of the candidates for Co-Funded, Co-Programmed and Institutionalised European Partnerships according to Horizon Europe structure

Source: Technopolis group (2020)

¹⁷ Horizon Europe Regulation (common understanding), Annex Va.

¹⁸ Shadow configuration of Strategic Programme Committee for Horizon Europe. The list of candidate European Partnerships is described in “Orientations towards the Strategic Plan of Horizon Europe” - Annex 7

¹⁹ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47)

There are only three partnerships for which implementation as an Institutionalised Partnership under Article 185 is an option, i.e. European Metrology, the EU-Africa Global Health partnership, and Innovative SMEs. Ten partnerships are candidates for Institutionalised Partnerships under Article 187. Overall the initiatives can be categorised into ‘horizontal’ partnerships and ‘vertical’ partnerships.

The ‘horizontal’ partnerships have a central position in the overall portfolio, as they are expected to develop methodologies and technologies for application in the other priority areas, ultimately supporting European strategic autonomy in these areas as well as technological sovereignty. These ‘horizontal’ partnerships are typically proposed as Institutionalised or Co-programmed Partnerships, in addition to a number of EIT KICs, they cover mainly the digital field in addition to space, creative industries and manufacturing, but also the initiative related to Innovative SMEs. ‘Vertical’ partnerships are focused on the needs and development of specific application areas, and are primarily expected to support enhanced environmental sustainability thereby addressing Green Deal related objectives. They also deliver on policies for more people centred economy, through improved wellbeing of EU citizen and the economy, like health related candidate European Partnerships.

2.2. Assessing the necessity of a European Partnership and possible options for implementation

Horizon Europe Regulation Article 8 stipulates that Institutionalised European Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

For all candidate Institutionalised European Partnerships the options considered in this impact assessment are the same, i.e.:

- Option 0 – Baseline option – Traditional calls under the Framework Programme
- Option 1 – Co-programmed European Partnership
- Option 2 – Co-funded European Partnership
- Option 3 – Institutionalised Partnership
 - Sub-option 3a Institutionalised Partnerships based on Art 185 TFEU
 - Sub-option 3b Institutionalised Partnerships based on Art 187 TFEU

2.2.1. Option 0 - Baseline option – Traditional calls

Under this option, strategic programming for R&I in the priority area will be done through the mainstream channels of Horizon Europe. The related priorities will be implemented through **traditional calls** of Horizon Europe covering a range of actions, mainly R&I and/or innovation actions but also coordination and support actions, prizes or procurement. Most actions involve consortia of public and/or private actors in ad hoc combinations, while some actions are single actor (mono-beneficiary). There will be no dedicated implementation structure and no support other than what is foreseen in the related Horizon Europe Work Programme. This means that discontinuation costs/benefits of predecessor initiatives should be factored in for capturing the baseline situation when relevant.

Under this option, strategic planning mechanisms in the Framework Programme will allow for a high level of flexibility in the ability of traditional calls to respond to particular needs over time, building upon additional input in co-creation from stakeholders and programme committees involving Member States. The Union contribution to addressing the priority covers the full duration of the initiative, during the lifetime of Horizon Europe. Without a formal EU partnership mechanism, it is less likely that the stakeholders will develop a joint Strategic Research Agenda and commit to its implementation or agree on mutual commitments and contributions outside their participation in funded projects.

2.2.2. European Partnerships

Under this set of options, three different forms of implementation are assessed: Co-funded, Co-Programmed, Institutionalised European Partnerships. These have **commonalities that cannot serve as a distinguishing factor in the impact assessment process**. They are all based on agreed objectives and expected impacts and underpinned by Strategic Research and Innovation Agendas / roadmaps that are shared and committed to by all partners in the partnership. They all have to follow the same set of criteria along their lifecycle, as defined in the Horizon Europe Regulation (Annex III), including ex ante commitment from partners to mobilise and contribute resources and investments. The Union contribution is defined for the full duration of the initiative for all European Partnerships. The Horizon Europe legal act introduces few additional requirements for Institutionalised Partnerships, e.g. the need for long-term perspective, strong integration of R&I agendas, and financial contributions.

Figure 2 - Key differences in preparation and implementation of European Partnerships

Type	Legal form	Implementation
Co-Programmed	Contractual arrangement / MoU	Division of labour , whereby Union contribution is implemented through Framework programme and partners' contributions under their responsibility.
Co-Funded	Grant Agreement	Union provides co-funding for an integrated programme with distributed implementation by entities managing and/or funding national research and innovation programmes
Institutionalised based on Article 185/187 TFEU	Basic act (Council regulation, Decision by European Parliament and Council)	Integrated programme with centralised implementation

The main differences between the different forms of European Partnerships are in their preparation and in the way they function, as well as in the overall impact they can trigger. The Co-Programmed form is assessed as the simplest, and the Institutionalised the most complex to prepare and implement. The functionalities of the different form of Partnerships – compared to the baseline option – are presented in Figure 3. They relate to the types of actors Partnerships can involve and their degree of openness, the types of activities they can perform and their degree of flexibility, the degree of commitment of partners and the priority setting system, and their ability to work with their external environment (coherence), etc. These key distinguishing factors will be at the basis of the comparison of each option to determine their overall capacity to deliver what is needed at a minimised cost.

Figure 3 Overview of the functionalities provided by each form of European Partnerships, compared to the traditional calls of Horizon Europe (baseline)

Baseline: Horizon Europe calls	Option 1: Co-Programmed	Option 2: Co-Funded	Option 3a: Institutionalised Art 185	Option 3b: Institutionalised Art 187
Type and composition of actors (including openness and roles)				
<p><u>Partners:</u> N.A., no common set of actors that engage in planning and implementation</p> <p><u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules</p>	<p><u>Partners:</u> Suitable for all types: private and/or public partners, foundations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules</p>	<p><u>Partners:</u> core of national funding bodies or government-mental research organisations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> limited, according to national rules of partner countries</p>	<p><u>Partners:</u> National funding bodies or governmental research organisation</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations</p>	<p><u>Partners:</u> Suitable for all types: private and/or public partners, foundations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations</p>
Type and range of activities (including additionality and level of integration)				
<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions</p> <p><u>Additionality:</u> no additional activities and investments outside the funded projects</p> <p><u>Limitations:</u> No systemic approach beyond individual actions</p>	<p><u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake</p> <p><u>Additionality:</u> Activities/investments of partners, National funding</p> <p><u>Limitations:</u> Limited systemic approach beyond individual actions</p>	<p><u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake</p> <p><u>Additionality:</u> National funding</p> <p><u>Limitations:</u> Scale & scope depend on participating programmes, often smaller in scale</p>	<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach</p> <p><u>Additionality:</u> National funding</p>	<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds).</p> <p><u>Additionality:</u> Activities/investments of partners/ national funding</p>
Priority-setting process and directionality				
<p><u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years.</p> <p><u>Limitations:</u> Fully taking into account existing or to be developed SRIA/ roadmap</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Input to FP annual work programme drafted by partners, finalised by EC (comitology)</p> <p>Objectives & commitments set in contractual arrangement</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by EC</p> <p>Objectives & commitments set in Grant Agreement</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by EC</p> <p>Objectives & commitments set in legal act</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by EC (veto-right in governance)</p> <p>Objectives & commitments set in legal act</p>
Coherence: internal (Horizon Europe) & external (other Union programmes, national programmes, industrial strategies)				
<p><u>Internal:</u> Coherence between different parts of the FP Annual Work programme can be ensured by EC</p> <p><u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Limited synergies with other Union programmes & industrial strategies. If MS participate, with national/ regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Synergies with national/ regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Synergies with national/ regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Synergies with other Union programmes and industrial strategies</p> <p>If MS participate, with national/ regional programmes & activities</p>

2.2.2.1. Option 1 - Co-programmed European Partnership

This form of European Partnership is **based upon a Memorandum of Understanding or a Contractual Arrangement** signed by the Commission and the private and/or public partners. Private partners are represented by industry associations, which also support the daily management of the partnership. This type of partnership would allow for a large degree of flexibility for the activities, partners and priorities to continuously evolve. The commitments of partners are political efforts described in the contractual arrangement and the contributions from partners are provided in kind more than financially. The priorities for the calls, proposed by the Partnership's members for integration in the Horizon Europe's Work Programmes, are subject to further input from Member States (comitology) and Commission services. The Union contribution is implemented within the executive agency managing Horizon Europe calls for research and innovation projects proposals. The full array of Horizon Europe instruments can be used, ranging from research and innovation (RIA) types of actions to coordination and support actions (CSA) and including grants, prizes, and procurement.

2.2.2.2. Option 2 – Co-funded European Partnership

The Co-funded European Partnership is **based on a Grant Agreement** between the Commission and a consortium of partners, resulting from a specific call in the Horizon Europe Work Programme. This form of implementation only allows to address public partners at its core. Typically these provide co-funding to a common programme of activities established and/or implemented by entities managing and/or funding national R&I programmes. The recipients of the EU co-funding implement the initiative under their responsibility, with national funding/resources pooled to implement the programme with co-funding from the Union. The expectation is that these entities would cover most if not all EU Member States. Calls and evaluations would be organised centrally, beneficiaries in selected projects would be funded at national level, following national funding rules.

2.2.2.3. Option 3 – Institutionalised European Partnership

This type of Partnership is the most complex and high-effort arrangement, and requires meeting additional requirements. Institutionalised European Partnership are **based on a Council Regulation (Article 187 TFEU or a Decision by the European Parliament and Council (Article 185 TFEU))** and are implemented by dedicated structures created for that purpose. These regulatory needs limit the flexibility for a change in the core objectives, partners, and/or commitments as these would require amending legislation. The basic rationale for this type of partnership is the need for a strong integration of R&I agendas in the private and/or public sectors in the EU in order to address a strategic challenge. It is therefore necessary to demonstrate that other forms of implementation would not achieve the objectives or would not generate the necessary expected impacts, and that a long-term perspective and high degree of integration is needed. For both Article 187 and 185 initiatives, contributions from partners can be in the form of financial and in-kind contributions. Eligibility for participation and funding follows by default the rules of Horizon Europe, unless a derogation is introduced in the basic act.

Option 3a - Institutionalised Partnerships based on Article 185 TFEU

Article 185 of the TFEU allows the Union to participate in programmes jointly undertaken by Member States and limits therefore the scope to **public partners** which are Member States and Associated Third Countries. This type of Institutionalised Partnership aims therefore at reaching the greatest possible impact through the integration of national and EU funding,

aligning national strategies in order to optimise the use of public resources and overcome fragmentation of the public research effort. It brings together R&I governance bodies of most if not all EU Member States (legal requirement: at least 40% of Member States) as well as Associated Third Countries that designate a legal entity (Dedicated Implementation Structure) of their choice for the implementation. By default, participation of non-associated Third Countries is not foreseen. Such participation is possible only if it is foreseen in the basic act and subject to conclusion of an international agreement.

Option 3b - Institutionalised Partnerships based on Article 187 TFEU

Article 187 of the TFEU allows the Union to set up joint undertakings or any other structure necessary for the efficient execution of EU research, technological development and demonstration programmes. This type of Institutionalised Partnership brings together a stable set of **public and private partners** with a strong commitment to taking a more integrated approach and requires the set-up of a dedicated legal entity (Union body, Joint Undertaking (JU)) that carries full responsibility for the management of the Partnership and implementation of the calls. Different configurations are possible:

- Partnerships focused on creating strategic industrial partnerships where, most often, the partner organisations are represented by one or more industry associations, or in some cases individual private partners;
- Partnerships coordinating national ministries, public funding agencies, and governmental research organisations in the Member States and Associated Countries;
- Or a combination of the two: the so-called tripartite model.

Participation of non-associated Third Countries is only possible if foreseen in the basic act and subject to conclusion of an international agreement.

2.3. Overview of the methodology adopted for the impact assessment

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines²⁰ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This also integrates **key selection criteria for European Partnerships**.

Box 2 Summary of European Partnerships selection criteria²¹

- **Effectiveness** in achieving the related objectives and impacts of the Programme;
- **Coherence** and synergies of the European Partnership within the EU R&I landscape;
- **Transparency & openness** as regards the identification of priorities and objectives and the involvement of partners & stakeholders from the entire value chain, backgrounds & disciplines;
- Ex-ante demonstration of **additionality** and **directionality**;
- Ex-ante demonstration of the partners' **long term commitment**.

2.3.1. Overview of the methodologies employed

In terms of **methods and evidence used**, the impact assessments draw on an external study covering all candidate Institutionalised European Partnerships in parallel to ensure a high level of coherence and comparability of analysis, in addition to an horizontal analysis.²² For all initiatives, the understanding of the overall context of the candidate institutionalised

²⁰ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

²¹ For a comprehensive overview of the selection criteria for European Partnerships, see Annex 6.

²² Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Study for the European Commission, DG Research & Innovation

European Partnerships relied on desk research, including among others the lessons learned from previous partnerships. This was complemented by the analysis of a range of quantitative and qualitative evidence, including evaluations of past and ongoing initiatives; foresight studies; statistical analyses of Framework Programmes application and participation data, and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options, as described below. Public consultations (both open and targeted) supported the comparative assessment of the policy options. For each initiative, up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition, the analysis was informed by the results of the Open Public Consultation run between September and November 2019, the consultation of Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of initiatives.

A more detailed description of the methodology and evidence base that were mobilised, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

2.3.2. *Method for identifying the preferred option*

The first step of the assessments consisted in scoping the problems that the initiatives are expected to solve given the overall economic, technological, scientific and social context, including the lessons to be learned from past and ongoing partnerships on what worked well and less well. This supported the identification of the objectives of the initiative in the medium and long term with the underlying intervention logic – showing how to get there.

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has then been adapted to introduce “**key functionalities needed**” - making the transition between the definition of the objectives and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1). In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options while allowing at the same time a structured comparison of the options not only as regards their effectiveness, efficiency and coherence, but also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)²³.

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made compared to the baseline. Therefore, for each of these

²³ The criterion on the ex-ante demonstration of partners' long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

aspects the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. This includes the discontinuation costs/benefits of existing implementation structures when relevant. The policy options are then scored compared to the baseline with a + and – system with a two-point scale, to show a slightly or highly additional/lower performance compared to the baseline. A scoring of 0 of a policy option means that it would deliver as much as the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options²⁴.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach²⁵ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account²⁶. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs of each candidate initiative.²⁷ The table shows the overall administrative, operational and

²⁴ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

²⁵ For further details, see Better Regulation Toolbox # 57.

²⁶ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

²⁷ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership the costs of preparation and implementation increase only marginally compared to the baseline (<1%), but lead to an additional R&I investment of at least the same amount than the Union contribution²⁸ (efficiency of 98% for the overall investment).
- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2,3 times the Union contribution²⁹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution³⁰. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution³¹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0				↑↑
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0				↑↑
Ex-ante Impact Assessment for partnership		0			↑↑↑
Preparation of EC proposal and negotiation		0			↑↑↑
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0				↑
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				

²⁸ Minimum contributions from partners equal to the Union contribution

²⁹ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

³⁰ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

³¹ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC	0				↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**)³². In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

For the **identification of the preferred option**, the scorecard analysis builds a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

As a last step, the alignment of the preferred option with key criteria for the selection of European Partnerships is described, reflecting the outcomes of the ‘**necessity test**’.³³ The monitoring and evaluation arrangements are concluding the assessment, with an identification of the key indicators to track progress towards the objectives over time.

2.4. Horizontal perspective on candidate Institutionalised European Partnerships

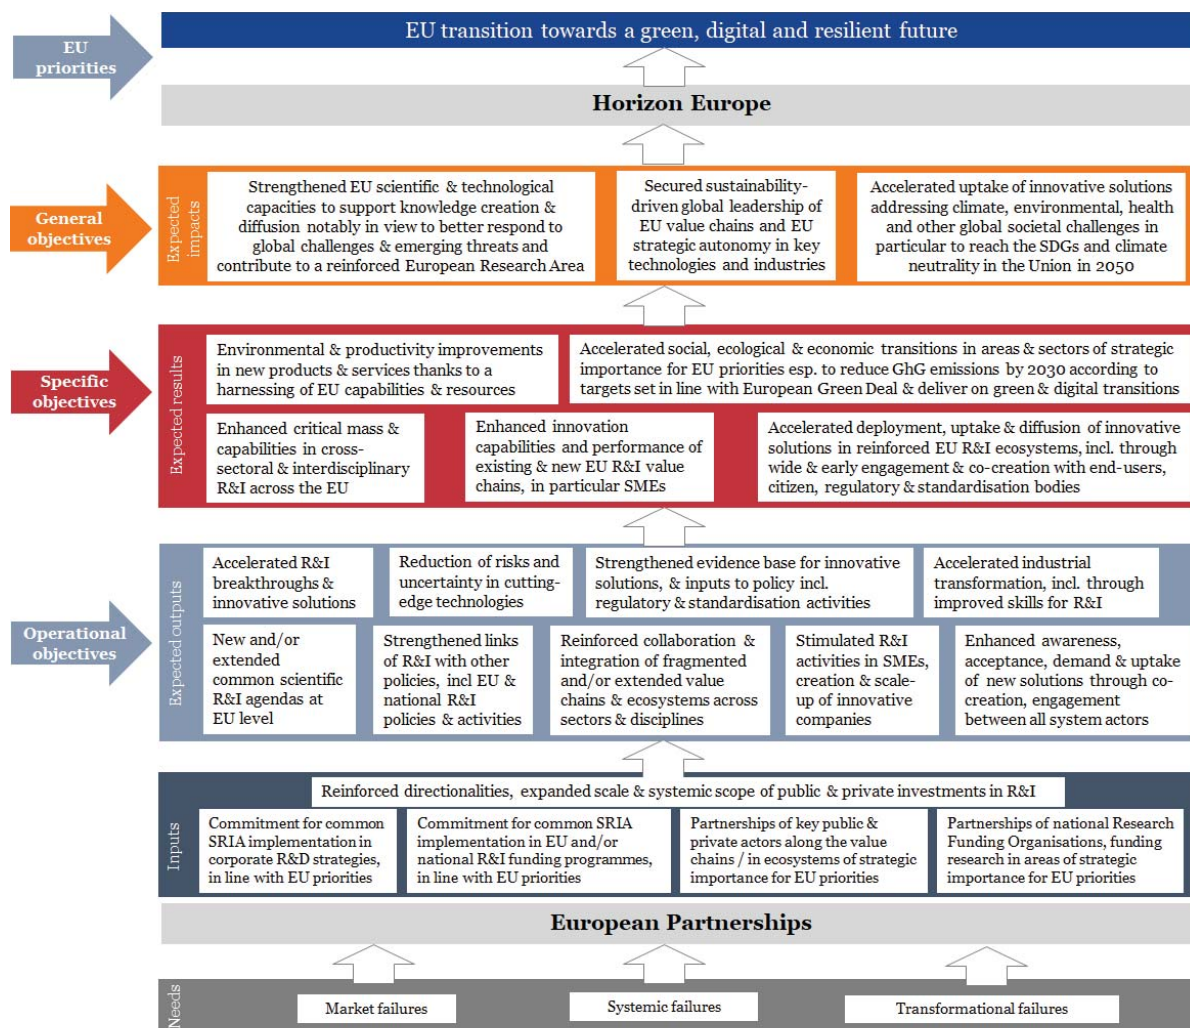

2.4.1. Overall impact orientation, coherence and efficiency needs

The consolidated **intervention logic** for the set of candidate Institutionalised European Partnerships in the Figure below builds upon the objectives as reported in the individual impact assessments.

³² More details on the methodology can be found in Annex 4.

³³ Certain aspects of the selection criteria will be further addressed/ developed at later stages, notably in the context of preparing basic acts (e.g. Openness and Transparency; Coherence and Synergies), in the Strategic Research and Innovation Agendas (e.g. Directionality and Additionality), and by collecting formal commitments (Ex-ante demonstration of partners’ long-term commitment).

Figure 5 – Overall intervention logic of the European Partnerships under Horizon Europe

Source: European Commission, DG Research & Innovation, Unit A2 Programme Analysis and Regulatory Reform, adapted from Technopolis Group (2020)

When analysed as a package the 12 candidate Institutionalised European Partnerships are expected to support the achievement of the European policy priorities targeted by Horizon Europe by pursuing the following joint general objectives:

- Strengthening and integrating EU scientific and technological capacities to support knowledge creation and diffusion notably in view to better respond to global challenges and emerging threats and contribute to a reinforced European Research Area;
- Securing sustainability-driven global leadership of EU value chains and EU strategic autonomy in key technologies and industries; and
- Accelerate the uptake of innovative solutions addressing climate, environmental, health and other global societal challenges contributing to Union strategic priorities, in particular to reach the Sustainable Development Goals and climate neutrality in the Union in 2050.

In terms of specific objectives, they jointly aim to:

- Enhance the critical mass and scientific capabilities in cross-sectoral and interdisciplinary research and innovation across the Union;
- Accelerate the social, ecological and economic transitions in areas and sectors of strategic importance for Union priorities, in particular to reduce greenhouse gas

emissions by 2030 according to the targets set in line with the European Green Deal, and deliver on the green and digital transition;

- c) Enhance the innovation capabilities and performance of existing and new European research and innovation value chains, in particular SMEs;
- d) Accelerate the deployment, uptake and diffusion of innovative solutions in reinforced European R&I ecosystems, including through wide and early engagement and co-creation with end-users, citizen and regulatory and standardisation bodies;
- e) Deliver environmental and productivity improvements in new products and services thanks to a harnessing of EU capabilities and resources.

In terms of their operations, taking an horizontal perspective on all initiatives allows for the identification of further possible collective efficiency and coherence gains for more impact:

- **Coherence for impact:** The extent and speed by which the expected results and impacts will be reached, will depend on the scale of the R&I efforts triggered, the profile of the partners involved, the strength of their commitments, and the scope of the R&I activities funded. To be fully effective it comes out clearly that future partnerships need to operate over their whole life cycle in full coherence with their environment, including potential end users, regulators and standardisation bodies. This relates also to the alignment with relevant EU, national or regional policies and synergies with R&I programmes. This needs to be factored in as of the design stage to ensure a wide take-up and/or deployment of the solutions developed, including their interoperability.
- **Collaboration for impact:** Effectiveness could also be improved collectively through enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems. An adequate governance structure appears in particular necessary to ensure cross-fertilisation between all European Partnerships. This applies not only to initiatives where similar R&I topics are covered and/or the same stakeholders involved or targeted, but also to the interconnections needed between the ‘thematic’ and the ‘vertical’ Partnerships, as these are expected to develop methodologies and technologies for application in EU priority areas. Already at very early stages of preparing new initiatives, Strategic Research and Innovation Agendas and roadmaps need to be aligned, particularly for partnerships that develop enabling technologies that are needed in other Partnerships. The goal should be to achieve greater impacts jointly in light of common challenges.
- **Efficiency for impact:** Potential efficiency gains could also be achieved by joining up the operational functions of Joint Undertakings that do not have a strong context dependency and providing them through a common back-office³⁴. A number of operational activities of the Joint Undertakings are of a technical or administrative nature (e.g. financial management of contracts), or procured from external service providers (e.g. IT, communication activities, recruitment services, auditing) by each Joint Undertaking separately. If better streamlined this could create a win-win situation for all partners leading to better harmonization, economies of scales, and less complexity in supervision and support by the Commission services.

³⁴ See Annex 6 for an overview of key functions/roles that could be provided by a common back office.

2.4.2. *Analysis of coherence of the overall portfolio of candidate initiatives at the thematic level*

Looking at the coherence of the set of initiatives at the thematic level, the “**digital centric**” initiatives have a strong focus on supporting the digital competitiveness of the EU ecosystem. Their activities are expected to improve alignment and coordination with Member States and industry for the development of world-competitive EU strategic digital technology value chains and associated expertise. Addressing the Key Digital Technologies, the 5G and 6G connectivity needs as part of a Smart Networks and Services initiative and the underlying supercomputing capacities through a European High Performance Computing initiative present potential for synergies that can be addressed through cooperative actions (e.g. joint calls, coordinated support activities, etc.). They may as well profit from and contribute to Partnerships envisaged for Photonics, AI, data, robotics, Global competitive space system and Made in Europe, together with the EIT Digital. Synergies between these initiatives and several programmes (Digital Europe and Connecting Europe as well as cohesion programmes) are needed in areas where EU industry has to develop leadership and competitiveness in the global digital economy. They are expected to impact critical value chains including on sectors where digital is a strong enabler of transformation (health, industrial manufacturing, mobility/transport, etc.).

The **transport** sector have to respond to systemic changes linked to decarbonisation and digitalisation. Large scale R&I actions are needed to prepare the transition of these complex sectors to provide clean, safer, digital and economically viable services for citizens and businesses. Past decades have shown that developing and implementing change is difficult in transport due to its systemic nature, many stakeholders involved, long planning cycles and large investments needed. A systemic modernisation of the air traffic management infrastructure through an Integrated Air Traffic Management initiative should ensure safety and sustainability of air transport, while a Clean Aviation initiative should focus on the competitiveness of tomorrow’s clean aircrafts made in Europe. The initiative for Transforming Europe’s rail system would comprehensively address the rail sector to make it a cornerstone in tomorrow’s clean and efficient door-to-door transport services, affordable for every citizen as well as the most climate-friendly mode of transport for freight. Connected and Automated Mobility is the future of road transport, but Europe is threatened to fall behind other global regions with strong players and large harmonised markets. The initiative Safe and Automated Road Transport would bring stakeholders together, creating joint momentum in digitalising road transport and developing new user-based services. Stronger links and joint actions will be established between initiatives to enable common progress wherever possible. The Clean Hydrogen initiative would be fundamental to that regard. Synergies would also be sought with partnerships driving the digital technological developments.

To deliver a deep decarbonisation of highly emitting industrial sectors such as the steel, transport and chemical industries would require the production, distribution and storage of **hydrogen** at scale. The candidate hydrogen initiative would have a central positioning in terms of providing solutions to the challenges for sustainable mobility and energy, but also is expected to operate in synergies with other industry related initiatives. The initiative would interact in particular with initiatives on the zero emission road and water transport, transforming Europe’s railway system, clean aviation, batteries, circular industry, clean steel and built environment partnerships. There are many opportunities for collaboration for the delivery and end-use of hydrogen. However, the Clean Hydrogen initiative would be the only partnership focused on addressing hydrogen production technologies.

Metrology, the science of measurement, is an enabler across all domains of R&I. It supports the monitoring of the Emissions Trading System, smart grids and pollution, but also

contributes to meeting demands for measurement techniques from emerging digital technologies and applications. More generally, emerging technologies across a wide range of fields from biotechnologies, new materials, health diagnostics or low carbon technologies are giving rise to demands requiring a world-leading EU metrology system.

The initiative for a **Circular Bio-based Europe** is intended to solve a shortage of industry investments in the development of bio-based products whose markets do not have yet certain long-term prospects. The **Innovative Health Initiative** and **EU-Africa Global Health** address the lack of investments in the development of solutions to specific health challenges. The initiative on **Innovative SMEs** supports innovation-driven SMEs in participating in international, collaborative R&I projects with other innovative firms and research-intensive partners. As a horizontal initiative it is expected to help innovative SMEs to grow and to be successfully embedded in global value chains by developing methodologies and technologies for potential application in the other partnership areas or further development by the instruments of the European Innovation Council.

The description of the interconnections between all initiatives for each Horizon Europe cluster is provided in the policy context of each impact assessment and further assessed in the coherence assessment for each option.

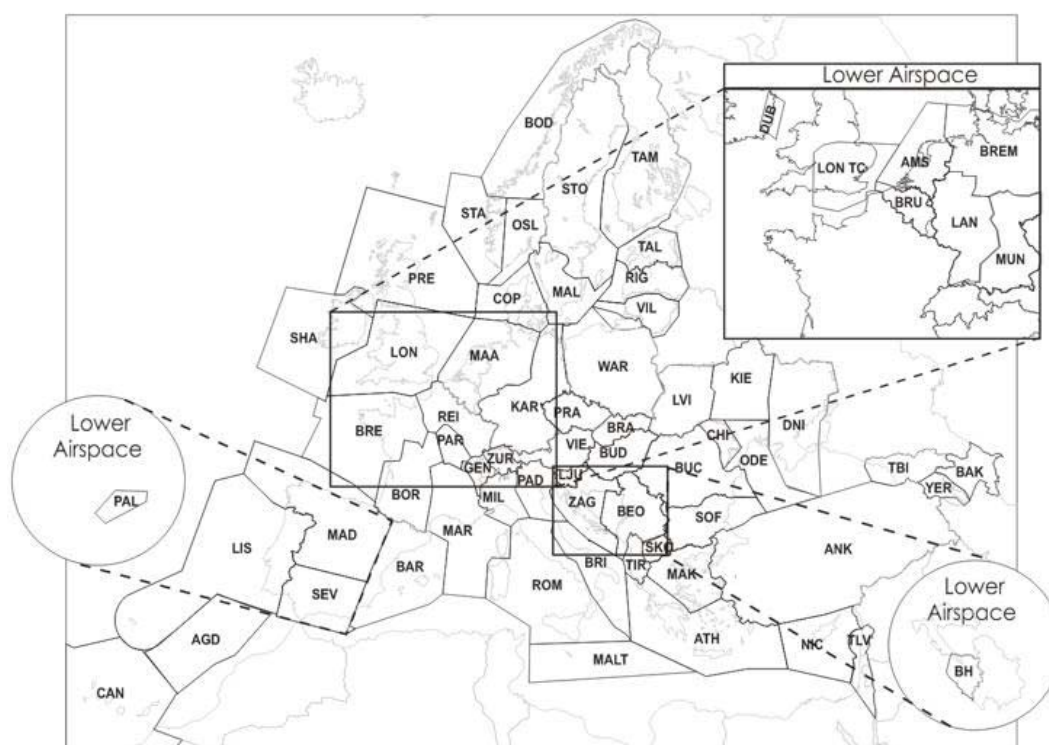

PART 2 - THE CANDIDATE EUROPEAN PARTNERSHIP FOR INTEGRATED AIR TRAFFIC MANAGEMENT

1. INTRODUCTION: POLITICAL AND LEGAL CONTEXT

Free movement of people and goods within the internal market is one of the cornerstones of the European Union's society and economy. The EU transport policy ultimately aims to serve the interests of European citizens and businesses by providing ever greater connectivity³⁵, the highest level of safety and security and barrier-free markets.

Air Traffic Management (ATM³⁶) is an activity for air transport encompassing ground and airborne systems that assist all types of manned and unmanned aircraft to safely depart from an aerodrome, transit airspace, and land at a destination aerodrome. Typically, before a flight takes place, any aircraft files a Flight Plan and sends it to a central European repository. However, for safety reasons, Air Traffic Controllers (ATCOs) can handle only a limited number of aircraft at one time. Computers used for flow management across the European network calculate the intended trajectory where an aircraft will be at any given moment and check that the ATCOs in that airspace can safely cope with the flight. If they cannot, the aircraft has to wait on the ground until it is safe to take off.

Figure 6 – A map of the European airspace

During the flight (en route) ATM ensures that aircraft are safely separated and safeguarded from adverse weather in the airspace and at the airports where they land and take off. Control

³⁵ Connectivity is also key in ensuring the economic, social and territorial cohesion of Member States enshrined in the Lisbon Treaty as a fundamental objective of the Union

³⁶ Regulation (EC) No 549/2004, Article 2(10): 'air traffic management (ATM)' means the aggregation of the airborne and ground-based functions (air traffic services, airspace management and air traffic flow management) required to ensure the safe and efficient movement of aircraft during all phases of operations'

towers at airports are a concept familiar to the public, but aircraft are also separated en-route by various “invisible” Air Traffic Control Centres (ACCs) as illustrated in the map above³⁷.

The current areas of responsibility of ACCs are designed mainly based on national boundaries. There are some examples of ACCs involving cross-border management of airspace. Each ACC works with sub-divided portions of airspace called sectors which may be grouped together or operated individually depending on level of traffic.

These subdivisions are clearly suboptimal and were addressed by the Single European Sky initiative of the Union's in 2004 seeking to reform the European air traffic management system through a series of actions carried out in four different levels (institutional, operational, technological and control and supervision) with the aim of improving the performance of the European airspace in terms of capacity, safety, efficiency and environmental impact.

In this context, the Single European Sky ATM Research (SESAR) project constitutes the fundamental “technological pillar” of the Single European Sky initiative, driving the ATM innovation cycle that brings new concepts through inter-related definition, development and deployment activities into operations, as illustrated below:

Figure 7 –SESAR and the ATM innovation cycle

R&I is the core of the SESAR project, driven by the European ATM Master Plan³⁸. The Master Plan is periodically updated to reflect new technology breakthroughs, evolving aviation expectations, and evolutions in EU policy and economy adjusting to emerging challenges within ATM.

The latest version of the Master Plan, adopted in December 2019 and supported by the entire aviation community and the EU Member States, identifies the vision for achieving a Digital European Sky³⁹ by 2040. This is a vision of a digital aviation infrastructure which is resilient, flexible and able to handle the future growth and diversity of air traffic safely and efficiently,

³⁷ Eurocontrol/Network Manager, 2018

³⁸ <https://www.sesarju.eu/masterplan>

³⁹ Blueprint for a Digital European Sky, Publication Office of the European Union, ISBN 978-92-9216-129-3

while minimising the environmental impact. The Master Plan defines what the current R&I programme is expected to deliver by 2035⁴⁰ and describes what the future programme still has to develop to implement the vision.

The Master Plan is therefore a clearly established and agreed roadmap for the future of ATM industrial and academic research, beyond the current or the potential upcoming partnership.

Building on the ATM Master Plan, parties interested to invest in the upcoming partnership have already prepared a detailed Strategic Research and Innovation Agenda laying down nine roadmaps for the technologies that need to be developed and demonstrated during the next Union long-term budget cycle.

It is to be noted that the brand ‘SESAR’ comprises development AND deployment (for more detail see Box 3 below). For the latter distinct financing and a distinct governance (outside the R&I domain) are in place.

This document focuses on assessing the most effective, efficient and coherent way of implementing an initiative under Horizon Europe that would focus on joint European research and innovation activities for modernising and integrating Air Traffic Management systems in Europe.

1.1. Emerging challenges in the field

Achieving the ambitious goal of climate neutrality by 2050 calls for the EU to ensure a deep decarbonisation of the air transport sector. The aviation industry has committed in the long-run to bring into service a new generation of aircraft that will be cleaner and quieter (based on alternative propulsion systems, new airframes and energy sources). However, this ambitious target cannot be achieved if ATM does not allow aircraft and airspace users to fully exploit their potential and thus to reduce emissions to a maximum.

Therefore, ATM must evolve at a faster pace than today to bring environmental benefits in the shorter term. Indeed, despite the ATM modernisation efforts undertaken in the past years, 5 to 10% of CO₂ emissions⁴¹ generated by flights are still thought to be avoidable and caused by a fragmented ATM infrastructure that does not fully exploit the advantages of digitalisation and automation. The avoidable emissions can be explained by unnecessarily long trajectories, congestion in the air and at airports, and thus higher CO₂ emissions, delays and higher costs for the provision of air navigation services.

Furthermore, while the economic outlook resulting from the COVID 19 pandemic is too early to predict, it is clear that due to its nature, air transport has been among the hardest hit sectors. IATA, the aviation industry’s trade body, has warned that some 25 million jobs in both the aerospace and aviation sectors are at risk if governments do not step in with lifelines⁴². These are not normal times and the pressure on the ATM infrastructure to embrace a more digital future to become more cost efficient, resilient and scalable to fluctuations (up or down) in demand for air transport has never been higher. Moreover, experiences from previous crises situations have shown that traffic will pick-up and increase beyond the pre-crises levels.

⁴⁰ Date at which it is deemed possible to secure full entry into operations of the technology and processes developed by the existing Programme

⁴¹ European ATM Master Plan Edition 2020

⁴² IATA Press Release No 28 07 April 2020

Innovation in ATM has progressed over the past decade thanks to the SESAR programme. However, there are still a number of remaining challenges, including the very sub-divided ATM systems as explained above, which will require a more rapid digitalisation of the ATM infrastructure to further focussing efforts and acceleration of the development, industrialisation and market uptake of innovations that would increase the level of collaboration and automation in ATM through a data rich and cyber-secured connected ATM ecosystem. Such an evolution also poses a number of regulatory challenges as the sovereignty of Member States in relation to their airspace needs to be respected and a higher degree of digitalisation and automation would make service delegation agreements between States less important.

The sector is still at the early stages of decarbonisation and digitalisation, and massive investments across the entire air transport value chain are necessary to shorten the innovation life cycles (from approximately 30 years today to 5-10 years). In order to achieve this acceleration, ATM must tackle risks such as market failure for first movers, fragmentation among players and lack of critical mass. The ATM industry supports a wide range of applications in transport (passengers and cargo, new emerging forms of mobility such as urban air mobility), defence & security (military, law enforcement), the digital economy (such as drones for the collection of data or to bring Internet connectivity to rural and remote communities).

Addressing these multiple challenges in a rapidly evolving and demanding context requires a significant collective effort in boosting cooperation and investment on breakthrough innovations that cannot be addressed by any single stakeholder or Member State alone as, by essence, aviation is international and requires common and coordinated action.

1.2. EU relative positioning in the field

Air transport is a key driver for European integration and economic prosperity. The aviation sector employs close to 2 million people and overall supports between 4.8 million and 5.5 million jobs in Europe⁴³, directly and indirectly. Altogether, this generates EUR 110 Billion in GDP in the EU, while the overall impact, including tourism, is as large as EUR 510 billion⁴⁴. Europe's citizens and businesses are connected today thanks to the 30 000 daily flights carrying about 1.1 billion passengers per year.

The European air traffic management (ATM⁴⁵) system supports mobility by providing the infrastructure to ensure the safe and secure separation of aircraft and the efficient flow of air traffic. It is a safety critical infrastructure, which is significantly regulated to ensure the highest possible performance standards. Put in other words, there can be no aircraft in the air without ATM which is currently provided in Europe at a cost to airspace users of about 10 billion EUR per year⁴⁶.

Europe hosts the world leaders in ATM technology and manufacturing industry^{47, 48}. Considering the shared and complex nature of this infrastructure, no single company or state can realise that digital transformation alone.

⁴³ Aviation Strategy for Europe: Maintaining and promoting high social standards, COM(2019) 120 final

⁴⁴ Source: European Commission, an Aviation Strategy for Europe, COM/2015/0598 final

⁴⁵ Regulation (EC) No 549/2004, Article 2(10): 'air traffic management (ATM)' means the aggregation of the airborne and ground-based functions (air traffic services, airspace management and air traffic flow management) required to ensure the safe and efficient movement of aircraft during all phases of operations'

⁴⁶ Source Eurocontrol, Central Route Charge Office, 2018 Report on the Operation of the Route Charges System

⁴⁷ Frost & Sullivan, Global Commercial Air Traffic Management Market, Forecast to 2025

Considering the cross-border and safety critical nature of air transport, developing the infrastructure and the underlying technology to support the realisation of the Single European Sky cannot be done by individual stakeholders or Member States.

The race for setting the next generation of standards requires more intensive global coordination in the context along the International Civil Aviation Organisation (ICAO). Europe's current leading position, through major players in ATM technology, SESAR and data platform providers, cannot be taken for granted. Competition is raising. New aviation nations like China are putting European leadership to the test, as is the renewed strengthening of protectionism worldwide. If the Union wants the European technology to continue to be backbone of global aviation infrastructure, the EU should continue its support for the European ATM innovation cycle⁴⁹. This cycle is a unique model of integration of different phases of innovation process involving a wide range of public and private partners governed by a dedicated EU-wide legal framework and incentive mechanisms linking technological innovation with policy and performance objectives. The political and economic weight of the initiative involving all EU Member States allows the Union to enjoy an influential position in global for a.

The safety of air traffic is and will continue to be the central focus of the partnership. This means that safety and cyber security are embedded in the design of every single solution coming out of SESAR and are regularly screened throughout validation and demonstration exercises under the close regulatory supervision of EASA, who should play an even bigger role in the upcoming partnership.

Box 3 Support for the field in the previous Framework Programmes – key strengths & weaknesses identified

What has been/is being done with EU research and innovation funding until now

European ATM Research & Innovation (R&I) is currently coordinated by the SESAR Joint Undertaking (SESAR JU)⁵⁰. Created in 2007⁵¹ under FP7 and extended in 2014⁵² under Horizon 2020, the SESAR JU currently manages the SESAR 2020 R&I programme (SESAR development phase) and will end its activities by 31 December 2024.

The objective of the SESAR JU is⁵³ “*to ensure the modernisation of the European air traffic management system by coordinating and concentrating all relevant research and development efforts in the Community*”.

What has or is being achieved so far

The current partnership has laid down a solid foundation that will enable a rapid start of activities under the new partnership/configuration. More specifically, the Master Plan (co-owned by industrial stakeholders, the Member States, the Commission and Eurocontrol)

⁴⁸ AeroSpace and Defence Industries Association of Europe (ASD) 2019 facts & figures report

⁴⁹ AeroSpace and Defence Industries Association of Europe (ASD) High-Level Position on Aeronautics in the next Framework Programme (FP9)

⁵⁰ an Institutionalised Partnership established under Article 187 of the Treaty on the Functioning of the European Union (TFEU)

⁵¹ See Council Regulation (EC) n°219/2007 of 27 February 2007

⁵² See Council Regulation (EU) No 721/2014 of 16 June 2014

⁵³ As defined by Council Regulation (EC) No 219/2007 of 27 February 2007 on the establishment of a Joint Undertaking to develop the new generation European air traffic management system (SESAR), as amended.

provides both, the vision of where the European ATM system should be by at the end of the next Union long-term budget (2035) and the common roadmap to achieve it. The two generations of the partnership preceding the upcoming initiative have solidified a close cooperation model sustained by clear governance arrangements and a multitude of working arrangements used by various specialists to cooperate at technical level.

To date, **the SESAR JU has delivered close to 100 ATM Solutions⁵⁴ that are being deployed and are delivering benefits at over 300 locations across Europe^{55,56}**, under the coordination of the SESAR Deployment Manager.

Whether implemented individually or in combination, the SESAR solutions can bring benefits in key performance areas, such as cost and operational efficiency, capacity, safety, security and the environment.

The SESAR JU has also changed the mind-set of the industry, who has become more cooperative and dedicated to achieving the common Union policy priorities in ATM.

There is also a close and well-tested cooperation with the industrialisation and deployment processes in the sector.

The main intervention areas for the upcoming partnership have already been central to the work of the current partnership. Some key achievements include:

- *Digitalisation*: the partnership was able to significantly advance the maturity of technologies enabling the virtualisation of ATM (Virtual & Augmented Reality applications, Remote Tower operations, Virtual Centres) some of which are already in implementation across Europe (Remote Towers).

- *Environment*: the partnership was able to advance the maturity of technologies promising to enable the reduction of CO₂ emissions per flight by up to 4% some of which are already in implementation across Europe such as Free Route operations (to fly more direct trajectories)

- *Drones*: in 2017, the European Commission mandated the SESAR JU to coordinate all R&I activities related to the safe integration of drone integration into airspace. As a result, 19 project were launched covering exploratory research and large-scale demonstration projects that addressed all aspects of drone operations, as well as the enabling technologies and required services. The results of these projects helped shape the first regulatory proposal to establish an initial harmonised framework for drone operations in Europe (EASA regulation on U-space).

How the new partnership will integrate the findings of previous evaluations

The partnership approach has proven to work in the context of ATM. It contributes to focusing and rationalising Research & Innovation efforts and investments in Europe on agreed priorities driven by the Union's policy objectives. The upcoming partnership will not only continue to engage all current types of stakeholders but it will expand its membership to new emerging actors in the sector, including drones manufacturers or drones services providers, as well as actors from the space and communications sectors.

As identified by the evaluation report, the administrative procedures and IT systems have caused concerns for the beneficiaries. The Commission has simplified the rules for

⁵⁴ <https://www.sesarju.eu/newsroom/brochures-publications/sesar-solutions-catalogue>

⁵⁵ Guidance Material for SESAR Deployment Programme Implementation Monitoring View 2019, SDM, September 2019

⁵⁶ Interactive map available at: <https://www.sesardeploymentmanager.eu/single-european-sky-deployment/>.

participation with the Proposal for the Horizon Europe Programme and has constantly been working to address IT concerns faced by the JUs and their members.

The work does not stop at the end of the research phase. To make a difference, the results of the partnership (SESAR solutions) have to be easy to standardise, certify and industrialise into products that can deliver tangible improvements into the real world operational environment.

To this end, the new Joint Undertaking will have a stronger role in coordinating and facilitating the industrialisation process for the SESAR solutions.

With the upcoming partnership, we also hope to break the traditional approach in aviation where innovation is often delayed by potential and non-documented safety concerns. The future partnership will develop & demonstrate the application of digital solutions (relying on higher levels of automation, AI, etc.) which will ultimately lead to smaller margins for human & system errors and improved safety.

What are the key areas for improvement & unmet challenges?

A number of systemic challenges already identified in the interim evaluation of SESAR JU⁵⁷ risk derailing the progress already achieved and will have to be better addressed in a new ATM research initiative. These challenges include:

- i) Defining and maintaining stable long-term objectives
- ii) Reinforcing the accountability of the SESAR JU and prioritising EU support to R&D solutions that promote defragmentation and a competitive environment⁵⁸.
- iii) Shortening the long research and industrialisation cycles, to secure a faster deployment and entry into operations of SESAR solutions;
- iv) Addressing funding concentration, and the need to ensure that there is enough transparency and openness to new participants, especially to entities from countries where participation was so far low;
- v) Improving knowledge management and transfer, links to academia and research institutes to improve the scientific base on ATM in the EU.

1.3. EU policy context beyond 2021

A new momentum to improve ATM is given by the "European Green Deal"⁵⁹, which identifies aviation as a key sector that needs a rapid change in paradigm to achieve the ambitious goal of climate neutrality by 2050. The European Green Deal refers explicitly to reducing aviation emissions.

The ATM infrastructure should be modernised at a more rapid pace to bring environmental benefits in the shorter term by improving the efficiency of ATM services in the European airspace. Digitalisation will radically transform Europe's ATM infrastructure contributing to a smarter, more sustainable, connected and accessible to all air transport.

⁵⁷ Commission Staff Working Document - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, SWD (2017) 339 final

⁵⁸ European Court of Auditors Special Report No 18/2017

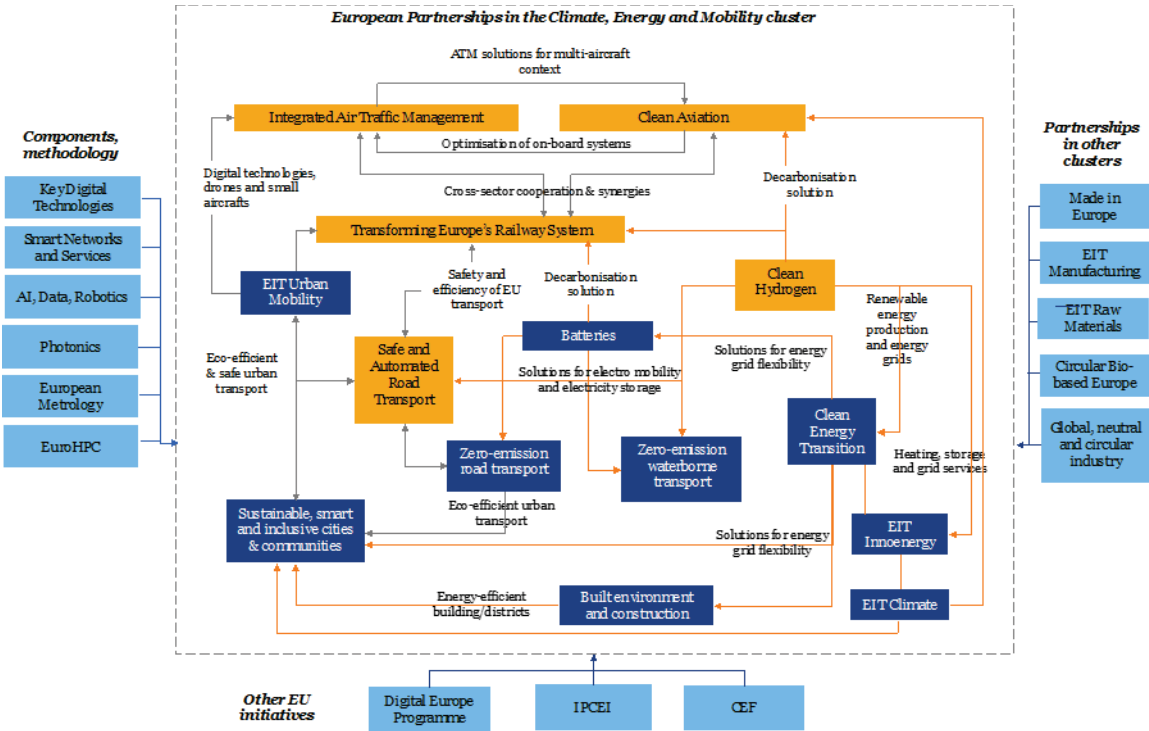

⁵⁹ European Commission (2019), COMMUNICATION FROM THE COMMISSION TO THE EUROPEAN PARLIAMENT, THE EUROPEAN COUNCIL, THE COUNCIL, THE EUROPEAN ECONOMIC AND SOCIAL COMMITTEE AND THE COMMITTEE OF THE REGIONS, The European Green Deal, COM(2019) 640 final

Under the proposed Horizon Europe programme, the R&I activities funded under the **Pillar II Cluster Climate, Energy and Mobility** aim at contributing to the attainment of three of the six main ambitions for Europe: ‘A European Green Deal’, ‘a people-centred economy’ and ‘A Digital Europe’. Pillar II supports several of the Sustainable Development Goals, particularly Climate Actions (SDG13), Sustainable Cities and Communities (SDG11) and Industry Innovation and Infrastructure (SDG9)⁶⁰.

The Integrated Air Traffic Management partnership is one of the European institutionalised Partnership candidates proposed to be established and funded under this cluster. It seeks to bring together a broad range of stakeholders in the sector (technology providers, innovators, start-ups, academia, airspace users, service providers and the military) to support the digital transformation of ATM infrastructure and services. It also falls under the new Commission’s vision of a digital European sky⁶¹ that by 2040 would eliminate any environmental waste caused by the aviation infrastructure.

Building upon the experience of the current SESAR Joint Undertaking, it is one of the envisaged European Partnerships to “accelerate competitiveness, safety and environmental performance of EU air traffic, aviation and rail”. There is a relatively high number of candidate partnerships in the mobility sub-cluster in different mobility application areas (i.e. air, rail and road transport). Fig. 1 shows the potential synergies between the candidate partnerships and the potential synergies with the energy and digital sub-clusters.

Figure 8: Potential interconnections between partnership initiatives in the Climate, Energy and Mobility cluster of Horizon Europe

Source: Technopolis Group (2020)

According to the European ATM Master Plan, the next generation of ATM systems underlying the digital European Sky shall be more automated and take greater advantage of

⁶⁰ Information on ATM contribution to SDGs is presented in Annex 6
⁶¹ Blueprint for a digital European Sky, EU Publication Office, December 2019

digital technologies such as big data and artificial intelligence (AI). Future ATM R&I therefore needs to be connected with wider R&I on:

- *Air Transport* (e.g. link with the candidate partnership on Clean Aviation). Traffic data from Eurocontrol shows that CO₂ emissions from aviation have grown by a higher percentage than the traffic growth⁶². Improvements in the environmental efficiency of aircraft may thus be negatively balanced by a fragmented ATM infrastructure. Therefore, the R&I roadmaps for ATM and Clean Aviation must be coordinated to maximise benefits, in particular on the environment.
- *Multi-modal transport*: ATM systems should be synchronised and exchange data with other transport modes (e.g. rail) to increase predictability and to enable through-ticketing or luggage reconciliation.
- *Digital technologies* (e.g. link with Key Digital Technologies, Smart Networks and Services, AI, Data and Robotics) and climate science including the latest information on climate change and its impacts⁶³. In particular ATM needs to be aware of and adapt to the evolution of technologies for data manipulation and distribution, cyber security, legal aspects (e.g. on data ownership, responsibility and liability issues), advanced decision making, including big data and artificial intelligence as well as scientific understanding of climatic impacts.

2. PROBLEM DEFINITION

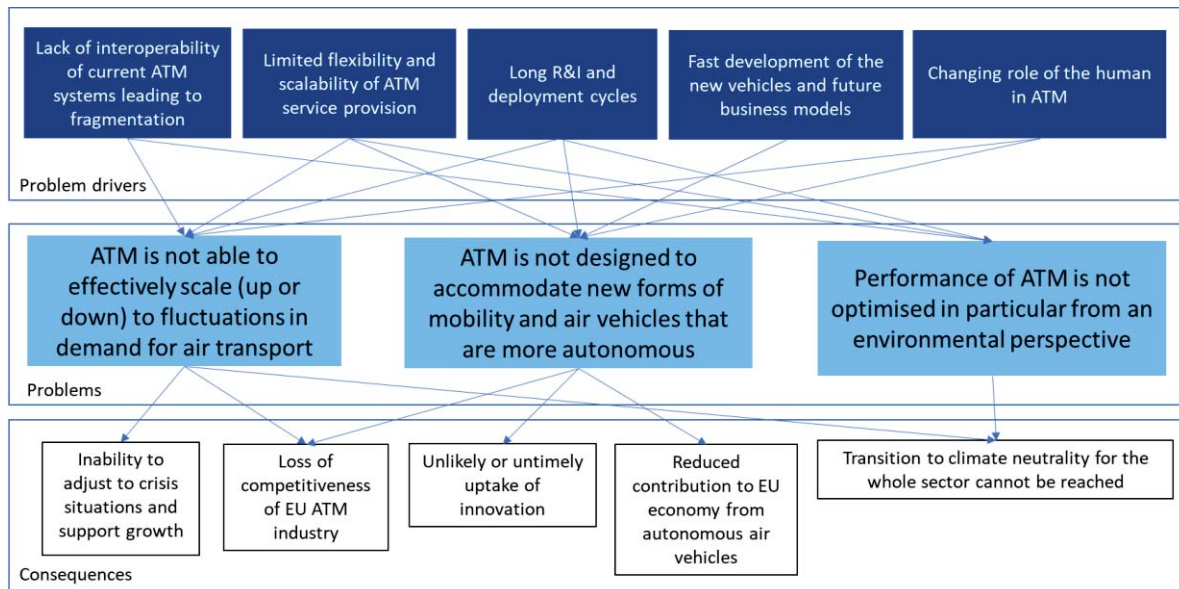

2.1. What are the problems?

Given the scale of the challenges identified in Section 1.1, the current scientific, technological and economic positioning of Europe in the field and the overarching Single European Sky policy context, three problems, all linked to limited scientific capacity and fragmentation of R&I efforts have been identified where coordinated EU research and innovation has an essential role to play:

- **Technological**: The current ATM systems and technologies in the EU are not digitalised and are therefore not able to effectively adapt to the fluctuations in demand for ATM services.
- **Economic**: The European ATM system and technologies are not designed to accommodate an increasing number of new forms of mobility and air vehicles that are more autonomous and use digital means of communication and navigation. Moreover, current technologies effectively prevent cross-border service provision in the internal market.
- **Environmental**: The performance of ATM is not optimised in particular from an environmental perspective resulting in unnecessary greenhouse gas emission of up to 10%.

Figure 9: Problem tree linked to the limited scientific capacity and fragmentation for the initiative on integrated Air Traffic Management

⁶² Comparison of January – October 2019 traffic vs January-October traffic 2017, for all Eurocontrol States departing flights: A 4.5% traffic increase generated a 7.5% increase in CO₂ emissions. Source: Eurocontrol, Network Manager.

2.1.1. The current ATM system has not been digitalised and is therefore not able to effectively scale (up or down) in line with fluctuations in demand for ATM services

Digitalisation has transformed a wide range of industries (with banking, media, retail, travel & tourism, and automotive as front runners) driven by data exchange, connectivity and automation. Transformation of the aviation industry and its supporting ATM infrastructure has already started, but in a post COVID 19 world, much deeper disruptions are expected to impact this traditional, vertically integrated, industry, characterised by slow development cycles and asset intensity.

These disruptions will come from increased and renewed demand to access the sky, new entrants reinventing mobility, new services enabled by data, faster innovation cycles, or customer expectations based on standards set by digital businesses.

They will come at a time of a very challenging outlook for the aviation industry that has been hit extremely hard by the COVID-19 crisis—even harder, perhaps, than by the events of 9/11 and the 2008 global financial crisis put together. However, this challenge will also come along with value migration within the value chain and between incumbents and new players – coming both from the digital industry and from regions such as Asia which may be in a position to benefit from the ongoing rebalancing of economic power.

The need to modernise the existing system through the development and application of emerging technologies such as digitalisation, automation and big data was a recurrent theme amongst the interviewed and throughout all the stakeholder categories⁶³.

Despite the successful deployment of some technologies developed under the SESAR project, Europe’s ATM infrastructure is still fragmented⁶⁴ and operates with a low level of automation support⁶⁵ and data exchange intensity (the primary communication technology in ATM today is high frequency radio through which decisions are exchanged by voice between air traffic controllers and pilots). This is the result of years of bespoke operations by national air navigation service providers that have until recently not sufficiently embraced digitalisation

⁶³ For an overview of the consultation activities that were carried out, and the views of the stakeholders, see Annex 2.

⁶⁴ Single European Sky: a changed culture but not a single sky, Special Report 18/2017, European Court of Auditors.

⁶⁵ European ATM Master Plan, Edition 2020, Figure 4

and underlines the importance of acting on a this joint effort at European level. As such, the current systems are monolithic, rigid, not scalable (i.e. providing the service where it is needed, in the amounts needed) and unable to exploit emerging digital technologies.

As a result, the periodic (e.g. weekdays vs weekends schedule) or occasional capacity shortage (leading to congestion) caused by unexpected traffic developments cannot be adequately addressed, and the new challenges, mainly the emergence of new airspace users (e.g. delivery drones), risk worsening the situation unless a new impetus is given to ATM modernisation through innovation. Many of the innovations needed are not “business as usual” or incremental but breakthrough solutions that combine digital and physical infrastructure capabilities that needs to be deployed in the entire ecosystem by air navigation service providers, airlines or airports.

Bringing these innovations to scale in the market is challenging considering the high degree of technological, regulatory or market risk the aviation industry faces, which so far has deterred or delayed private investment in its infrastructure⁶⁶. Addressing the multiple ATM challenges requires significant R&I investment in boosting cooperation and investment on innovations that cannot be addressed by any single stakeholder or Member State alone as the ATM infrastructure is shared and needs to rely on homogeneous standards⁶⁷, fit for the digital age, to foster innovation.

As seen prior to SESAR, national R&I programmes aimed at solving local problems, rather than addressing the network perspective at European level. This resulted in duplication of efforts on similar topics⁶⁸, leading to the adoption of different solutions generating even more fragmentation and inefficiencies. Finally, substantial R&I effort and coordination is still needed to improve the manufacturability of tomorrows digital ATM platforms and time to market to reduce innovation cycle from about 30 years to about 5-10 years.

This is due to the complexity of facilitating interactions between innovators, early movers and regulators to help develop regulatory frameworks that allow the benefits of digital technologies to be fully realised in a safety critical sector of our economy.

The majority of stakeholders, across all stakeholder groups, indicated that deployment needs to be accelerated by paying more attention: to implementation challenges, change management for deployment, and gaps between R&I and industrialisation.

2.1.2. The European ATM system is not designed to accommodate new forms of mobility and air vehicles that are more autonomous

Over 23,000 daily flights carrying one billion passengers per year (in 2018) connect Europe’s citizens, businesses, communities and cultures.

Hence, under normal circumstances with a saturated aviation infrastructure, air traffic in Europe is hitting its limits both in the air and on the ground, resulting in growing delays and unnecessary emissions. In addition, a multitude of new types of air vehicles, such as delivery drones and air taxis, will soon be seeking access to the airspace. The need for continued and more focussed coordinated R&I and validation of commonly agreed concepts is clear and urgent, in particular to support a robust economic recovery of Europe after the COVID 19 crisis.

⁶⁶ Blueprint for a Digital European Sky, Publication Office of the European Union, ISBN 978-92-9216-129-3

⁶⁷ The role of standards is discussed further in Annex 6.

⁶⁸ R&I prior to SESAR is described in Annex 6

The current European ATM infrastructure is reaching its limit in terms of ability to manage an ever increasing volume of air traffic⁶⁹ which means that the problem will resume as the COVID 19 crisis is over (at the time of writing this report the estimated time to recovery for airlines is estimated at 3 to 18 months⁷⁰). In 2018, air traffic delay attributable to the ATM short-comings doubled⁷¹. With sustained long-term traffic growth forecasted for the next 17 years resulting in a total traffic increase of 50%⁷² there is a risk that the level of delays could be 15 times higher if the capacity of current systems is not increased⁷³.

Figure 9 shows the predicted levels of delay and congestion in 2035 if more flexible, scalable and interoperable ATM solutions are not developed and implemented.

Figure 10: The predicted levels of delays by 2035

Source: A proposal for the future architecture of the European airspace, SJU, 2019.

When the airspace management capacity limit is reached, in order to maintain safety, additional constraints are imposed on flights (e.g. delaying or re-routing flights to avoid the saturated zone), resulting in delayed and longer flights, which impact negatively on the environmental and performance goals⁷⁴ of ATM⁷⁵.

Aircrafts flying in European skies are also becoming more autonomous, more connected, more intelligent, and more diverse⁷⁶. This means that there will be an emergence of a multitude of new types of air vehicles where there is no pilot to talk to: drones flying at low altitude, military medium altitude long endurance unmanned aircraft systems, automated air taxis, super-high altitude operating aircraft.

The markets for these “new entrants” are hindered by the lack of an integrated and harmonised traffic management concept and infrastructure that will allow the safe introduction of services and functionalities to support these operations in both new (e.g. urban) and traditional airspace. Without such systems to ensure safe operations, rules tend to be more restrictive and divers between EU Member States⁷⁷.

⁶⁹ Annex 6 provides further details of the limitations of the current ATM system.

⁷⁰ The Post-COVID-19 Flight Plan for Airlines, The Boston Consulting Group, March 31 2020

⁷¹ Eurocontrol Performance Review Report 2018: ATFM delay in 2018 was 1.74 minutes per flight; in 2017 it was 0.82 minutes per flight.

⁷² European Aviation in 2040 Challenges of Growth, Annex1 Flight Forecast to 2040, EUROCONTROL, 2018

⁷³ A proposal for the future architecture of the European airspace, SJU, 2019

⁷⁴ ATM performance requirements are regulated under Commission Implementing Regulation (EU) 2019/317 of 11 February 2019 laying down a performance and charging scheme in the single European sky

⁷⁵ In 2019, horizontal flight efficiency increased from 2.83% to 2.95%

(<https://www.eurocontrol.int/prudata/dashboard/vis/2019/>) as a result of measures to reduce delay by diverting traffic from congested areas (<https://www.eurocontrol.int/news/seven-measures-counteract-severe-delays>).

⁷⁶ Blueprint for a Digital European Sky, Publication Office of the European Union, ISBN 978-92-9216-129-3

⁷⁷ See for example: <https://dronerules.eu/en/professional>

Interviews: A majority of stakeholders agree that one of the needs of R&I in ATM is the inclusion of the key emerging challenges such as drones, U-space and other aerospace vehicles into the current system. Airspace users, SMEs, staff and supplier stakeholder groups did not directly cite the inclusion of drones, but did endorse the European ATM Master Plan as a good strategic agenda (which includes these emerging challenges).

2.1.3. The performance of ATM is not optimised in particular from an environmental perspective resulting in unnecessary greenhouse gas emission

There is growing pressure on the aviation sector to reduce its environmental footprint. Citizens in general and air passengers in particular increasingly expect eco-friendly, smart and personalised mobility options that allow them to travel seamlessly and efficiently. They want quick and reliable data to inform their travel choices, not only on schedules, prices and real-time punctuality, but increasingly also on environmental impacts. To deliver this new era in aviation, leveraging technology is key, as in the upcoming future new aircraft and infrastructure capabilities combined with regulatory changes hold the greatest promise to address climate changes in a post-pandemic aviation sector.

Indeed, while an energy transition (e.g. sustainable aviation fuels) is the only way in the long term (2050) to ensure carbon neutral air transport in the future, the ATM infrastructure in particular can be modernised at a more rapid pace and bring significant environmental benefits in the shorter term⁷⁸.

Today 5-10% of air transport's CO₂ emissions could be avoided due to inefficiencies in the ATM infrastructure⁷⁹ as aircraft trajectories are not sufficiently optimised from gate-to-gate perspective to reduce the environmental footprint of each flight (see figure 10 below). This is not negligible and would save 28 million tonnes of CO₂ per year, which is roughly equivalent to the CO₂ produced by 3.2 million people or the population in the metropolitan area of a city like Madrid⁸⁰.

To further understand the problem it is important to stress that the contribution of ATM infrastructure in reducing the climate change impacts of aviation can best be achieved by enabling aircraft to fly on their optimum (where applicable cross-border) 4D trajectory on the ground, in the climb, on-route and descent phases of flight - the optimum horizontal path from departure to destination flown at the most fuel efficient altitude. This is not the case today as illustrated by Figure 11 below. There are several factors that may influence whether such an optimum trajectory may be flown. One factor is data sharing, as all actors (e.g. airline, airports at departure and arrival, network manager and often multiple national air navigation and data service providers) involved in the execution of a given flight will have to plan and execute their services based on a shared and agreed 4D trajectory⁸¹. This call for a very broad engagement of stakeholders in the future partnership as later described in section 4.

Figure 11: Breakdown of gate-to-gate excess CO₂ emissions for an average flight in Europe

⁷⁸ IATA, Aircraft Technology Roadmap to 2050 which provides an overview and assessment of technology opportunities for future aircraft, including improved engine efficiency, aerodynamics, lightweight materials and structures as well as radical new configurations and propulsion systems

⁷⁹ European ATM Master Plan, Edition 2020, Figure 10

⁸⁰ European ATM Master Plan Companion Document on the Performance Ambitions and Business View

⁸¹ ICAO Environmental Report 2019

Source: European Aviation Environmental Report 2019, EASA, EEA and Eurocontrol.

Significant R&I effort is still needed to develop ATM technology enabling “perfect flights by design” (including for the next generation aircraft that will be cleaner and quieter) from an emission perspective eliminating all possible ATM infrastructure constraints that would result into a degradation of the optimum and thus generating extra emissions.

2.2. What are the problem drivers?

2.2.1. Lack of interoperability and fragmentation of current ATM systems

ATM infrastructure and services are provided by the Member States’ air navigation service providers, over their territories⁸². The current infrastructure is the result of historical operational and technical evolutions, primarily conducted at the national level, which have led to today’s fragmented system.

The cost of fragmentation of European ATM and communication and navigation services carries a high cost - around EUR 900m - EUR 1 400m annually, approximately 20-30% of the annual costs of air navigation service provision⁸³.

Initiatives such as SES and SESAR have led to improved interoperability and harmonisation but have not yet overcome this underlying fragmentation to enable truly seamless airspace operations⁸⁴.

To date however, as evidenced by the interim evaluation of the SESAR JU, the initiative has focussed on maturing solutions that optimise specific elements of ATM but has made slow progress on key enablers where there is limited industry consensus (for example, next generation datalinks and flight data processing) highlighting the need for greater emphasis on transformational technologies⁸⁵.

Stakeholder views: Interoperability was highlighted by many interviewees from ANSP, ATM institution, Member States, SESAR Joint Undertaking executives, staff, suppliers and U-space community stakeholder groups, as one of the key R&I needs and current problems of ATM. The responses show they believe that defragmentation is required in

⁸² This is the set-up for all the States members of ICAO. ICAO, Convention on International Civil Aviation, and its Annexes.

⁸⁵ Interim evaluation of the SESAR Joint Undertaking (2014-2016) operating under Horizon 2020. Expert Group Report, European Commission (2017).

order to achieve interoperability, amongst others.

2.2.2. *Limited flexibility and scalability of ATM service provision*

Scalability is the capability to provide air traffic services at the right time and in the right place (in line with demand fluctuations – up or down). Although the situation has improved, each air navigation service provider optimises its resources and capacity locally (through airspace organisation and staff availability), with little coordination at European level. This is a crucial issue because the majority of flights in the EU airspace are cross-border. Today, this process takes a significant amount of time and results in limited flexibility for routing, flexibility for allocation of controllers, and leads ATM services to be either over or under-dimensioned at any given point in time.

As air traffic grows or is subject to severe fluctuations in demand (such as the ones observed during the COVID-19 crisis), it becomes more important to be able to take a network (or pan-European) view. Prior to the crisis some portions of the EU ATM network were running close to their structural capacity limit. In that case, any unplanned perturbation at local or network level results in significant disruptions and consequent delays and greater impact on the environment. “The analysis showed that the European core area where traffic density is highest remains the problem area”⁸⁶.

2.2.3. *Long R&I and deployment cycles*

The ATM infrastructure is safety critical and shared across all Member States. Changes to this infrastructure therefore require working together across the whole aviation value chain (aircraft manufacturing, aircraft operations and infrastructure) and synchronising actions, even if some may have a negative business case on a given investment that needs to be addressed and overcome by creating confidence not only on technical feasibility but also in terms of on market uptake potential by a critical mass of early movers. That is why the ATM innovation cycles are long, as it often takes more than ten years from concept definition to deployment and entry in operations⁸⁷. The efforts of the SESAR JU have allowed reducing the R&I from about 10 to an average of 6 years, but a similar effort remains to be carried out for the industrialisation phase that ensures the transition of solutions from development to deployment.

ATM is heavily regulated: the safety and security-critical nature of the infrastructure is one of the reasons behind slow uptake, as each innovative solution needs to be proven not to decrease safety, or security and that it complies with national, regional and world-wide standards.

This in turn requires constant assessment of solutions as they are developed and matured across the TRL⁸⁸s. This can be a lengthy and often expensive process of collecting safety evidence, since no ATM procedure or tool can be implemented if it is not approved by either a local or European regulatory body.

⁸⁶ Performance Review Report: “An Assessment of Air Traffic Management in Europe during the Calendar Year 2018”, Performance Review Commission, 2018.

⁸⁷ For example, it took 15 years for Time Based Separation, which is a procedure aimed at more efficient management of arrivals into busy airports. See: EUROCONTROL Specification for Time-Based Separation (TBS) support tool for Final Approach - Ed. 1.0.

⁸⁸ Technology Readiness Level, as defined in the General Annexes of the Horizon 2020 Work Programme 2014-2015, Commission Decision C(2014) 4995, https://ec.europa.eu/research/participants/data/ref/h2020/wp/2014_2015/annexes/h2020-wp1415-annex-g-trl_en.pdf

During those time periods the solution under development evolves, due to the changing environment (i.e. economy, price of fuel, travel demand)⁸⁹. Innovations that are “robust”, in the sense of being solutions that address the changing requirements have the best chance of reaching deployment.

The ultimate decision to implement a new technology would need to be accepted by all the involved organisations to ensure interoperability across Europe. Therefore, a high level of consensus from all the ATM stakeholders – airspace users (including new operators of drones), air navigation service providers, airports, regulatory and standardisation bodies - is required to finalise the R&I and transition towards industrialisation and deployment.

The need to accelerate innovation in ATM has been cited often in recent years⁹⁰.

The majority of stakeholders interviewed, across all stakeholder groups, indicated that deployment needs to be accelerated by paying more attention: to implementation challenges, change management for deployment, and gaps between R&I and industrialisation⁹¹.

2.2.4. *Fast development of the new air vehicles and future business models*

New forms of air vehicles are emerging at an unprecedented rate – in particular drones and air taxis for urban air transport. At the moment, the infrastructure that would allow for, and safely manage this type and magnitude of operations, does not exist. The USA, China and Europe are looking into the necessary concepts to develop an unmanned air vehicle traffic management (UTM) system⁹².

The fast evolution of drones – in terms of operational roles and platform capabilities creates new issues for the ATM system. The majority of drone operations (e.g. small drones that do not have the range to reach the altitudes in controlled airspace) are not expected to take place in traditional controlled airspace⁹³. Instead, they will take place in what is currently referred to as uncontrolled airspace which is populated by general aviation flying by visual flights rules, and urban airspace which is not traditionally flown over but for which drones require access – for example for aerial photography, crowd surveillance or domestic deliveries.

This leads to three different issues:

- a) How best to accommodate drones in controlled airspace, where they will be expected to operate in accordance with current rules and regulations, but where the varying levels of performance of the air vehicle can cause control/safety issues?

⁸⁹ Bolić, T., 2012. Innovation Adoption and Adaptation in Air Traffic Control – Interaction of Organizations. Journal of Sociotechnology and Knowledge Development

⁹⁰ See for instance the Report of Wise Persons Group on the future of the Single European Sky, 2019

⁹¹ This statement from an R&D organisation stakeholder describes succinctly the issues around length of R&I and deployment cycles: “What often slows down the implementation is the development of standards and the regulatory approval. The direction and focus is really important to have – a good idea with a follow up plan (up to implementation) can bring about the innovation in ATM. Good idea without a follow up plan is not good, as is not good having a bad idea with the follow up plan. So, the screening of the ideas and results, and how they proceed through the research and development process is important.”

⁹² In the USA: <https://utm.arc.nasa.gov/index.shtml>, https://www.faa.gov/uas/research_development/traffic_management/; In China https://rpas-regulations.com/wp-content/uploads/2018/06/1.2-Day1_0910-1010_CAAC-SRI_Zhang-Jianping_UOMS-EN.pdf; In EU: <https://www.sesarju.eu/U-space>

⁹³ European ATM Master Plan: Roadmap for the safe integration of drones into all classes of airspace, SJU, 2018.

- b) How best to accommodate drones in uncontrolled airspace where they will need technological solutions to detect and avoid manned aircraft? Again, the size and performance of the drones is critical to design solutions.
- c) How best to integrate multiple drones into urban airspace in a safe manner acceptable to the local population?

Creating a European U-space infrastructure will require significant R&I⁹⁴ in various areas of technology (e.g. conflict detection and resolution between the drones, the communication between the drones, their operators and other involved actors), interfaces with air traffic management, security and cyber reliance, along with the availability of authorised & safe testing environments. As the size and performance of drones are constantly changing, these issues even harder to address – particularly for an industry that has seen only limited change in aircraft operating performance in the past several decades.

ATM institutions and the U-space community, that were interviewed, stated that new markets such as drones develop quicker than the ATM solutions. In this area, the lack of coordinated R&I included in the ATM programme, would leave Europe behind other regions, like China and USA, which are investing heavily in drones and UTM research and development.

2.2.5. *The changing role of the human in ATM*

ATM relies heavily on highly trained professionals able to solve complex situations on a regular basis. These professionals are able to handle a certain number of aircrafts and they represent about two thirds of the European ATM costs. On the other hand, the digital transformation of ATM triggers a radical increase in the dynamics of the system to secure its scalability (up - and also down, as the current crisis demonstrates) and resilience, ensuring that all air traffic is handled safely and efficiently, whatever the traffic scenario. In this context, the role of the human and of the interface between humans and the machines is a key driver for the success of the future system, as humans will continue to control the tools, use the support provided by machines to take decisions quickly and safely.

Digitalisation, automation virtualisation will generate a substantial change in the way ATM is organised and operated. No change of such magnitude can be successful without the implication and support of the staff concerned. R&I must have a strong connection with the operational staff and associate it to the development of the tools of the future, taking into full account the diversity of cultures, situations and labour laws within each State.

Change management, social dialogue, training and permanent staff involvement will be key requisites to the success of the European ATM modernisation and the achievement of the Digital European Sky.

2.3. **How will the problem(s) evolve?**

Unless the three problems linked to limited scientific capacity and fragmentation of R&I efforts are effectively addressed at EU level, it is likely that national programmes will re-

⁹⁴ Section 4.2.4 of European ATM Master Plan: Digitalising Europe's Aviation Infrastructure. SJU, 2019.

emerge on an ad-hoc basis, especially in a post-COVID 19 world, to solve specific local issues generating increased fragmentation⁹⁵.

In these circumstances, the technological problem will lead to:

- **Inability to adjust to crisis situations and to support growth:** after the financial crisis in 2008 it took until 2016 for the number of flights in Europe to return to the levels seen in 2007. In the current situation, not only have we seen airlines either stop flying or operate at a “de minimis” level, but airports close for flights too. Restarting is going to be a significant activity and should not be underestimated. This crisis provides nothing more than some “breathing space” for an ATM infrastructure that had already reached its structural capacity limits. The pressure on the ATM infrastructure to embrace a more digital future to become more cost efficient, resilient and scalable to fluctuations (up or down) in demand for air transport has therefore never been higher.
- **Loss of competitiveness of European industry players:** the industry has been one of the hardest hit with the COVID 19 crisis, with contracts cancelled, production halted and pleas for big bailouts. Unlike many other sectors in the digital economy, Europe is currently the world leader in aerospace and aviation infrastructure technology. Unless this opportunity is taken it is likely that Europe will lose its leadership position and become more dependent on imports from third countries.
- **Unlikely or untimely uptake of innovation** (i.e. lack of a common vision and needed evidence for standardisation and regulatory approval) that would therefore be less likely to be deployed to overcome inefficiencies at EU level, thus making it more difficult, time consuming and expensive to make the ATM system fit for addressing future challenges.

The economic problem described above will lead to:

- **Reduced contribution to EU economy from autonomous air vehicles:** drones provide new capabilities for government and defence applications, as well as for commercial business opportunities. The spread and development of civil drones depends on their ability to operate in various areas of the airspace. This requires significant R&I on drone traffic management⁹⁶ that, if not addressed, would reduce the estimated value of European drone market by EUR 10 billion annually by 2035 and over EUR 15 billion annually by 2050⁹⁷.

From an environmental perspective:

- **Transition to climate neutrality for the whole sector cannot be reached:** the aviation industry has committed in the long-run to bring into service a new generation of aircraft that will be cleaner and quieter (based on alternative propulsion systems, new airframes and energy sources) but this ambitious target cannot be achieved if ATM does not allow them to fly full exploiting their potential. ATM must evolve at a faster pace to bring environmental benefits in the shorter term.
- **Aircraft will fly inefficient routes, increasing environmental impact:** airspace congestion would impose inefficient routes on flights, increasing environmental

⁹⁵ See Annex X for further details on ATM R&I prior to SESAR.

⁹⁶ Including technological solutions for conflict avoidance and better communications between the drones and other actors, security & cyber reliance, along with the availability of authorised & safe testing environments.

⁹⁷ European Drones Outlook Study – Unlocking the value for Europe, SJU, 2016.

impact (additional 30 to 60 million tonnes of CO₂ over the period 2019-2035⁹⁸), and costs to airlines and passengers.

3. WHY SHOULD THE EU ACT?

3.1. Subsidiarity: Necessity of EU action

All identified problems described in Chapter 2 are currently being addressed at EU level:

- The Single European Sky defines the policy context;
- R&I is coordinated by the SESAR Joint Undertaking and
- Synchronised deployment is ensured through Common Projects.

Recent European Court of Auditors reports^{99,100} found that the current policy, R&I and deployment initiatives have generated a change process, but that more efforts are needed in order to realise the full benefits of ATM modernisation: *“It is therefore necessary to accelerate and better focus efforts on transforming the European ATM system into a digital, scalable and resilient network, through an approach coordinated at EU level”*.

This can only be achieved by transforming the current patchwork of national systems into a modern collaborative and distributed platform¹⁰¹, evolving from bespoke, product-based systems to a service, collaborative and adaptable network approach. Achieving an interoperable infrastructure is a prerequisite to unbundling the physical infrastructure from service provision and a fluid and secure access to ATM data. In this way air navigation services will be able to be provided irrespective of their physical location, at any moment and to any part of airspace. This requires significant R&I funding to develop and validate transformative technologies with a high degree of consensus from both Member States and the industry¹⁰².

Most stakeholders interviewed indicated that action from the EU was required to provide coordination and harmonisation across the ATM value chain. EU leadership will ensure that the European network benefits from a broad, synchronised implementation of the latest technology. Industrial stakeholders (suppliers and ANSPs) noted the need for long term benefits justify investment and overcome their individual interests. They support developing solutions based on a common architecture rather than developing their own products in isolation.

3.2. Subsidiarity: Added value of EU action

A modern, digital and efficient ATM system will support sustainable aviation growth in line with EU policies, namely the European Green Deal¹⁰³ and achieving a Europe fit for the digital age.

It is estimated that by 2050, a harmonised European ATM system could generate over EUR 1,800bn in benefits for Europe¹⁰⁴ that will boost EU competitiveness, innovation capacity and

⁹⁸ G.3.2 of A proposal for the future architecture of the European airspace, SJU, 2019.

⁹⁹ Single European Sky: a changed culture but not a single sky, Special Report 18/2018, ECA.

¹⁰⁰ The EU’s regulation for the modernisation of air traffic management has added value – but the funding was largely unnecessary, Special Report 11/2019, ECA.

¹⁰¹ A proposal for the future architecture of the European airspace, SJU, 2019.

¹⁰² Further details on the necessary transformational technologies are provided Annex 6.

¹⁰³ COM(2019) 640 final

¹⁰⁴ See Table 38 in Annex 6 for a detailed breakdown.

the position of its industry in the global market. Realising the benefits will largely depend on the ability of the sector to create the conditions to shorten the innovation life cycle for infrastructure modernisation. If these conditions are not created, the transformation will likely take significantly longer with negative implications for the environment, jobs and growth in Europe.

Addressing this challenge in a rapidly evolving and demanding context requires a significant collective effort in boosting cooperation and investment on innovations that cannot be addressed by any single stakeholder or Member State alone as, by essence, aviation is international and requires common and coordinated action. This is particularly true for the European infrastructure supporting aviation due to the scale and cross-border nature of the problems and the wide range of stakeholders involved. Only action at EU level can improve results in such a fragmented sector.

All stakeholders interviewed indicated the need for EU funding on ATM research to provide directionality and coherence due to the cross border nature of operations and the need for interoperability.

4. OBJECTIVES: WHAT IS TO BE ACHIEVED?

4.1. General objectives of the initiative

Based on the identified problems, the overall objective of the proposed initiative is to develop and validate ATM technological solutions that support the achievement of the Digital European Sky making the European airspace the most efficient and environmentally friendly sky to fly in the world and support the competitiveness and recovery of the aviation sector in a post-COVID crisis Europe.

The work to be carried out by the initiative will enable a substantial transition from current ATM systems to the new Digital European Sky vision of the European ATM Master Plan and will produce noticeable, quantifiable contributions to growth and climate targets in 2030 and pave the way for climate neutrality by 2050.

There is a significant change in scope compared to the current SESAR JU, with more focus on breakthrough innovations, industrialisation and market uptake. The following general objectives have been identified:

- Strengthen and integrate the EU's research and innovation capacity in the ATM sector, helping bring the European ATM into the digital age to make it resilient, scalable to fluctuations in traffic while enabling the seamless operation of the next generation of aircraft, which will be cleaner, quieter and more autonomous,
- Strengthen through innovation the competitiveness of manned and unmanned EU air transport and of the ATM services market to support a robust economic growth and recovery in a post-COVID 19 world in the EU,
- Develop and accelerate market uptake of innovative solutions to establish the Single European Sky airspace as the most efficient and environmentally friendly sky to fly in the world

These objectives address the aviation value chain, which was severely affected by the COVID 19 crisis, from a broad perspective and are aligned with the objectives of the Horizon Europe framework. Their achievement will contribute to several Sustainable Development Goals with

the most impact on SDG 9 (Industry, Innovation and Infrastructure), SDG 13 (Climate Action) and SDG 8 (Decent work and economic growth).

4.2. Specific objectives of the initiative

The future partnership will only be successful if all partners will continue to remain committed to the objectives established by the European ATM Master Plan. Significantly more efforts and investment than in the past are needed from all stakeholders involved to ensure the delivery of technical solutions able to advance smoothly through standardisation and certification processes.

Therefore, in order to achieve the general objectives, six specific objectives are defined. They respond to each of the problem drivers discussed in Section 2.2.:

- Develop a R&I ecosystem covering the entire ATM and U-space value chains allowing to build the Digital European Sky¹⁰⁵ defined in the European ATM Master Plan, enabling the collaboration and coordination needed between air navigation services providers and with airspace users to ensure that a single harmonised EU ATM system for both manned and unmanned operations;
- Develop and validate breakthrough ATM solutions supporting high levels of automation;
- Develop and validate the technical architecture of the Digital European Sky;
- Support an accelerated modernisation of ATM infrastructure through a network of demonstrators and facilitate the development of standards for industrialisation.
- Maintain a consensus-led strategy for EU ATM modernisation

Meeting the afore-mentioned specific objectives should be measured against the capacity of the future partnership to execute the following core activities:

- Organise and coordinate the SESAR definition (maintenance of the European ATM Master Plan), development and industrialisation phases (further developed in the SRIA) to stimulate and reinforce the EU scientific, operational and industrial ecosystem for innovation in aviation infrastructure;
- Develop and validate breakthrough ATM solutions, supporting high levels of environmental performance, resilience and scalability. The objective by 2030 is to deliver the solutions identified in the European ATM Master Plan for Phase D (“Digital European Sky”) at TRL 6;
- Accelerate market uptake by establishing a European network of large-scale digital sky demonstrators to build confidence and bridge the gap between research and implementation. The demonstrators should be closely connected to the standardisation and regulatory frameworks to advance the maturity of the solutions smoothly through standardisation and certification processes. The objective by 2030 is to accelerate market uptake (up to TRL 8) for a critical mass of “early movers” representing minimum 20% of the targeted operating environment in Europe.
- Facilitate interactions between innovators, early movers and regulators to help develop regulatory frameworks that allow the benefits of digital technologies to be fully realised with due consideration for the human dimension.

¹⁰⁵ ‘Digital European Sky ’ refers to vision of the European ATM Master Plan, seeking to transform Europe's aviation infrastructure enabling it to handle the future growth and diversity of air traffic safely and efficiently, while minimising environmental impact.

- Support the Union in coordinating global interoperability efforts and promote European R&I results in relevant international fora.

It is important to note that issues related to the policy, regulatory and financial framework have to be addressed in parallel and/or factored in so that the initiative is able to achieve its objectives and effectively contribute to the relevant EU policies and targets from a broader perspective. This could be addressed by future developments of the regulatory framework and EU aviation relevant policies and strategies.

Many of the respondents to the Open Public Consultation took the opportunity to underline key messages regarding the initiative:

The initiative should bring together the key stakeholders of the value chain in order to agree on the key European issues whilst keeping it manageable. It is important, as commented by some stakeholders across all the categories, to cover the UTM value chain and include other actors such as business aviation, regulators, communication service providers and satellite communication service providers, and, as said by all, a strong involvement of EASA and standardisation bodies.

Air navigation service providers and manufacturers agree that European R&I ATM has a strong position worldwide due to having built over years a coordinated programme, which has allowed Europe to have a strong voice in ICAO and set trends parts of the world. Interviewees also noted that closer cooperation and involvement of EASA and EUROCAE would support narrowing of the gap between the R&I and industrialisation phases.

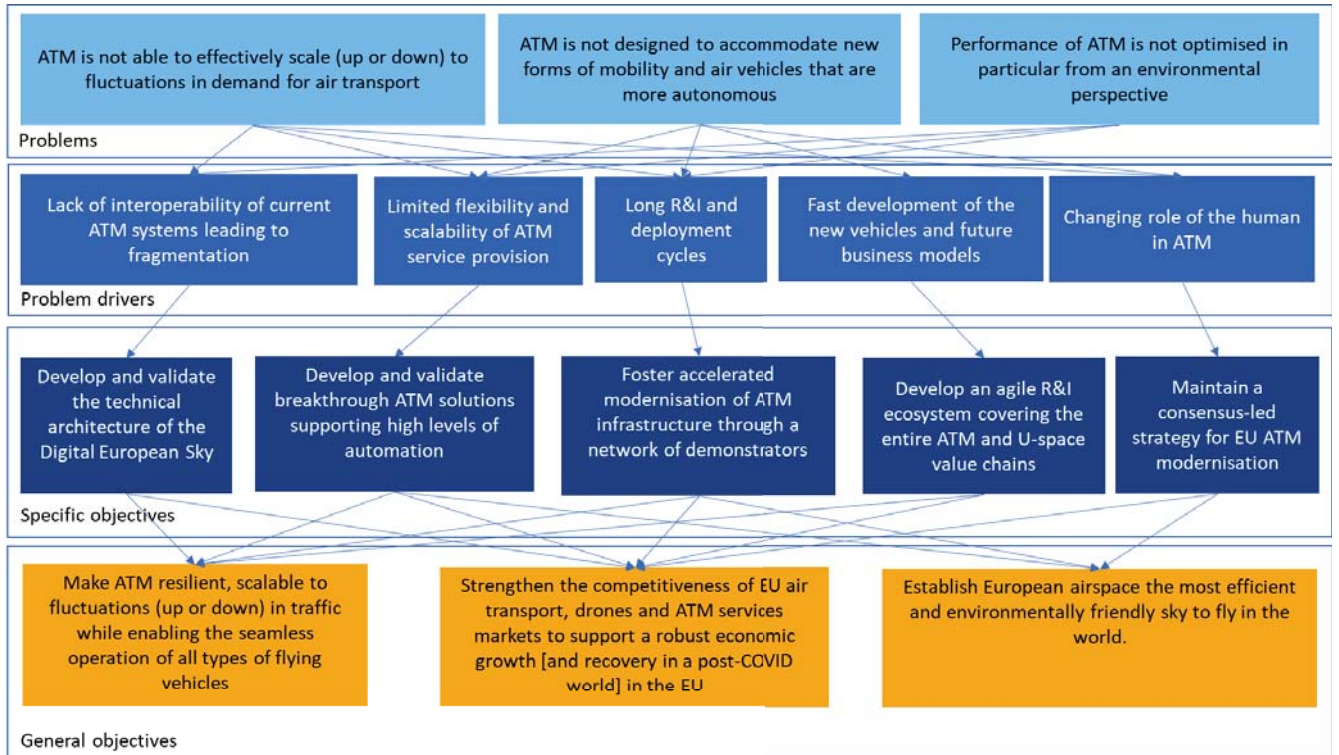

Stakeholders with long experience in ATM research recalled the period prior to the establishment of the SESAR JU and the adoption of the European ATM Master plan. They agree that in ATM, European network benefit is only achieved if efforts are coordinated and building on a commonly agreed Roadmap/Plan agreed between the industry, the Union and the Member States.

Stakeholders across all groups pointed out the need to close the industrialisation gap between R&I and deployment in order to support the pull through of breakthrough technologies.

4.3. Intervention logic

The relationship between the general and specific objectives of the initiative on integrated ATM R&I is shown in Figure 11.

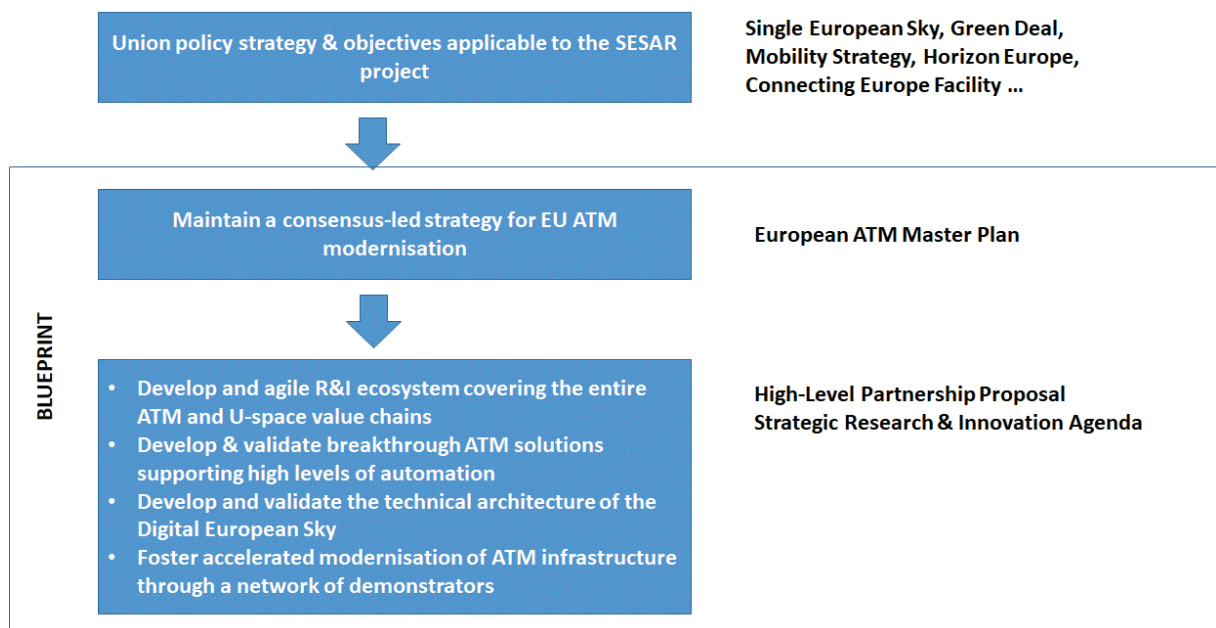

Figure 11: Intervention Logic for the initiative on integrated ATM

How the intervention logic fits in the broader policy context

As explained in Chapter 1, the investment into this initiative facilitates the development of technologies which support the success of the Single European Sky policy of the Union. Figure 12 below outlines how different planning instruments link with each other and relate to the policy.

Figure 12: Intervention Logic in the policy context

How would success look like?

Should the initiative deliver on its specific objectives, it is expected that it would result in the following impacts:

Scientific impacts

New scientific knowledge and reinforcement of EU scientific capabilities

If successful, the R&I ecosystem established and supported by this initiative would develop and validate new technological and operational ATM solutions that help develop new scientific knowledge and reinforcement of EU scientific capabilities. This impact should start being visible over the medium term and should continue even after the end of the R&I.

The development of ATM solutions would make use of new scientific methods, in particular digital technologies (e.g. big data, automation, AI, virtualisation). This would generate new data, use cases and applications that test and reinforce these technologies.

The planned R&I activities would require and involve a wide range of expertise from various scientific and engineering disciplines, such as aviation and infrastructure engineering, communications, operations research, computer science and thus helps build the cooperation and scientific exchanges between these branches.

Enhanced capacity among the next generation aviation professionals:

The benefits of bringing the ATM infrastructure into a digital age to users and businesses in the whole aviation value chain (i.e. including aircraft manufacturers and aircraft operators) and the economic growth that could come via their productivity contributions, are compelling¹⁰⁶. This will not only contribute to a more resilient and sustainable EU economy that creates jobs but also help expand the knowledge base and skill sets of academia and companies' staff.

In order to be able to develop the needed ATM solutions, and to facilitate the best performing ATM in the future, next generation ATM professionals would need to be aware of this science. Apart from performing research, the goal of academia, in general, is to promote knowledge transfer to the next generation of professionals through the involvement of Ph.D. students and post-doctoral students in the R&I research activities. This would enhance the capacity among the next generation of aviation professionals, which would likely have a strong impact on the education of the next generation of experts. This impact would start being evident at the medium term and continue throughout the lifetime of the initiative.

Economic/technological impacts

Overall, this initiative will facilitate the setup of an aviation infrastructure that supports the growth and recovery of Europe in a post-COVID world and that opens up digital opportunities for people and business while enhancing Europe's position as a world leader in the digital economy.

If successful, the initiative would allow for an accelerated delivery of innovative ATM solutions needed for all types of aircraft operations that help improve the flexibility of the European ATM network and systems. This would allow for the **handing of additional flights and thus facilitating growth in the air transport sector**.

¹⁰⁶ European ATM Master Plan Edition 2020

Safely and efficiently integrating drones and drones traffic management systems with the ATM systems would facilitate **the ramp up of drones-related economic activities**, opening up the market for new types of drones services operators and drones traffic management service providers.

A Europe-wide agreed ATM architecture relying on inter-operable ATM solutions standardised and certified at European level would give Europe a strong voice at international level, where European technologies can and should be the backbone of global ATM modernisation plans coordinated by ICAO. This would boost the EU industry globally by enabling international agreements and contracts.

The economic impacts have been evaluated as part of the recent European ATM Master Plan update campaign¹⁰⁷ and assume an effective roll-out of R&I results into operations are summarised in Table 1.

The figures represent an estimated direct gross domestic product (GDP) contribution generated by SESAR in the ATM value chain (ATM equipment manufacturers, aircraft manufacturers, military, airspace users, ANSPs, Network Manager and airports). All calculations are available in the supporting document to the European ATM Master Plan Edition 2020 (titled “Master Plan Companion Document on the Performance Ambitions and Business View”).

Table 1: Expected economic impacts

Expected impacts	Quantification Method	Value
Ability to handle additional flights enabling growth in air transport	Direct benefits of ATM value chain Cumulative Benefit up to 2050	€510b
Enable new economic activity based on drones	Direct benefits of the U-space value chain Cumulative Benefit up to 2050	€350b
Boost EU industry globally through international agreements and the setting of global standards	Grow market share to 70% of the global market of approximately €4b per annum Cumulative Benefit up to 2050	€84b

Source: Master Plan Companion Document on the Performance Ambitions and Business View. 1.0, SJU, 2019.

Aviation is a resilient industry which has been hit by a number of shocks in the past. Whereas COVID-19 is currently creating unprecedented low traffic levels, in the medium to long term, there is little doubt that aviation will return to growth. Moreover, the COVID-19 crisis does not change the need for the European ATM system to become more automated, more scalable and more resilient in its support of European aviation while reducing the environmental impact and improving cost efficiency.

Societal impacts (including environmental impacts)

The contribution of ATM to passenger experience and to the implementation of efficient multimodality, including urban air mobility, will be a major factor in how the society will view the aviation industry in the future. The passenger experience will be optimised by

¹⁰⁷ Master Plan Companion Document on the Performance Ambitions and Business View. 1.0, SESAR, 2019.

focusing on departure and arrival punctuality on the aviation legs of the multimodal journey, reducing time spent at airports. Optimisation will also be achieved through the effective sharing of multimodal connection data with other modes of transport, enabling an integrated approach to reducing door-to-door travel time.

A digital European sky will ensure that passengers do not lose time at airports or in the air in Europe. In doing so, it could save yearly up to 14.5 million hours that passengers will be able to spend instead with their family or at work.

If the initiative is successful, and the R&I results implemented, the expected societal impacts would be reduced travel times, improved predictability, reduced delays and lower costs. This would improve both the passenger experience and business opportunities.

Table 2: Societal Impacts

Expected impacts	Quantification Method	Value
Improve passenger experience by reducing travel time, delays and costs	Indirect benefits for passengers and EU citizens. Cumulative Benefit up to 2050	€760 Bn

Source: Master Plan Companion Document on the Performance Ambitions and Business View. 1.0, 2019.

The figure of EUR 760bn corresponds to a monetisation of the societal impacts of SESAR to EU citizens. It was calculated by independent experts who assessed the passengers benefits from the additional mobility (more flight options) and time saved (lower delays and shorter flights). It also assesses the benefit for the European society of having lower air pollution and lower climate change impact - driven by lower fuel burn - per flight. All calculations are available in the supporting document to the European ATM Master Plan Edition 2020 (titled “Master Plan Companion Document on the Performance Ambitions and Business View”¹⁰⁸, section 4.2.3.3. “Indirect benefits for passengers and European citizens”).

In more concrete terms, focus areas include emission-free taxiing and solutions to optimise airport and terminal airspace operations, such as exceptional holdings and more continuous climb and descent operations, while curved, steep and/or segmented approaches and noise-preferential routes are being considered for deployment to address noise reduction. Urban air mobility will depend on electric or hydrogen-powered vehicles that will be emission free, with R&I ensuring that noise levels are minimised for the general public.

Environmental impacts

A digital European sky could save 28 million CO₂ tonnes per year, which is roughly equivalent to CO₂ produced by 3.2 million people or the population in the metropolitan area of a city like Madrid.

The technological progress resulting from this initiative would ultimately lead to optimising flight trajectories and traffic flow, i.e. planes being able to fly the cheapest, shortest route possible while maintaining the required high safety levels. This would contribute to the long-term goal of reducing aviation noise and gas emissions (i.e. 5-10% less CO₂ emissions per flight by 2035) from an ATM-operational perspective.

¹⁰⁸ <https://www.atmmasterplan.eu/>

The EUR 12bn. estimated impact corresponds to the fuel savings (and reduced emissions) that could be realised by aircraft operators with the current fleet.

Table 3: Expected Environmental Impacts

Expected impacts	Quantification Method	Value
Reducing aviation noise and gas emissions	Reduction of 240 kg to 450 kg of CO ₂ on average per flight due to improved flight efficiency Cumulative Benefit in terms of fuel savings up to 2050	€12b

Source: A proposal for the future architecture of the European Airspace, SESAR, 2019.

Open public consultation: A majority of stakeholders, across all stakeholder groups, pointed out that the initiative can and should make a significant contribution to the EU efforts to achieve climate-related goals – 54% chose very relevant, and 29% relevant. The two identified campaigns stated that it was very relevant (59%), or relevant (40%).

Social impacts

In ATM as in all industries, the human capital is a critical and an integral element of the system. Changing demands on ATM require a radical increase in the dynamics of the system to secure its scalability (up and down) and resilience, ensuring that all air traffic is handled safely and efficiently, even under the highest traffic growth forecast or during stagnation or unexpected downturn.

The goal of automation is not to replace the human but to optimise the overall performance of the socio-technical ATM system and maximise human performance. This will require the development of the role of the human in parallel with ATM concepts and technological developments. New tools are needed to support continuous, system-wide monitoring of all critical processing, including during degraded modes of operation or, for example, cyberattacks. New tools must also enable humans to make effective decisions, including where collaborative, co-adaptive and joint intelligence modes of decision-making are used. A move from executive control to supervisory control will require a thorough understanding of the implications for the humans and their interaction with the systems. The human-to-technology balance is likely to vary between domains, where some problems might be solved by automation with little human intervention, while other areas might require a human, monitored by an automated safety capability to solve the problem. Research will need to address all the roles, responsibilities and tasks of the different actors (airborne and ground, ATM and U-space, operating and technical), training needs and change management for the evolving roles as per the recommendations provided by the Expert Group on the Human Dimension of the Single European Sky.

4.4. What is needed to achieve the objectives – Key functionalities needed

Given the focus of the impact assessment on comparing different forms of implementation, the identification of “key functionalities needed” allows making the transition between the definition of the objectives and what would be crucial to achieve them *in terms of implementation*. These functionalities relate to the type and composition of actors that have to be involved, the type of range of activities that should be performed, the degree of directionality needed and the linkages needed with the external environment.

4.4.1. Type and composition of the actors to be involved

The core objective of the proposed initiative is to support an ambitious modernisation of European ATM enabling collaborative service provision based on high levels of automation. It is important the ATM solutions proposed and matured by the R&I are supported by the full range of ATM stakeholders. The future R&I on integrated ATM should therefore be open to:

- a) Suppliers of “ATM solutions”, i.e. air and ground system manufacturers and ATM data service providers.
- b) New entrants particularly active on emerging autonomy and connectivity solutions (such as but not limited to urban air mobility, U-space, mobile network operators).
- c) Operators and users of the system namely air navigation service providers, airport operators and airspace users – including both civil and military organisations.
- d) The Meteorological community such as MET service providers
- e) EASA and national authorities to ensure smooth progress through certification and regulatory processes.
- f) EUROCAE and other standardisation bodies to deliver the next generation standards
- g) EUROCONTROL (an inter-governmental organisation) as a key actor in European ATM with a large R&I capability and specific operational roles in terms of managing the ATM network.
- h) The European Space Agency (ESA) and satellite communication providers as the sector may allow to develop highly innovative solutions for the benefit of aviation
- i) Research establishments that mainly perform applied research and are increasingly engaging in supporting the introduction of breakthrough innovation into the market
- j) The ATM R&I community of universities and specialist SMEs that currently support exploratory research.
- k) The professional staff associations to ensure the involvement of operational staff in the development of new concepts as well as R&D validation activities
- l) The wider R&I community that could support the adaptation of new technologies (e.g. digitalisation, earth observation, satellite navigation, climate science, et.) to the ATM context.

4.4.2. Type and range of activities needed

Flexibility in the selection of projects, implementation and membership will be crucial to ensure that the partnership is empowered enough to deliver. In practice, there is need for a balance between long term vision and stability of the programme and flexibility (e.g. evolution in partners, adjustments in investment levels to advance – or not – to higher TRL levels etc.) to ensure it remains relevant and responsive to new market, industry and technological developments.

In order to ensure flexibility of implementation so as to reach its intended objectives the initiative should conduct the following activities:

- (I) Seek synergies with R&I programmes of other sectors and initiatives. In particular, strong links are already identified (but not limited to) with the candidate European Partnerships on clean aviation

- (II) Coordinating R&I actions ranging from concept to demonstration activities for a critical mass of early movers (covering all Technology Readiness Levels), ensuring inclusion of new actors and integration of extended value chains
- (III) Organising and coordinating the European ATM Master Planning activities defining the SESAR vision and the related development and deployment priorities and plans securing due involvement of all Member States
- (IV) Coordinating industrialisation processes fostering and acceleration of market uptake and solutions able to advance smoothly through open standardisation and certification processes
- (V) Co-creating solutions with end-users, emphasising the importance of flexibility in addressing different target groups over time (potential down-stream and end-users, public authorities and broader stakeholder communities), including industrial end users beyond the transport sector
- (VI) Facilitating flexible and efficient interactions between breakthrough innovators, early movers and regulators to help develop regulatory frameworks that allow the benefits of digital technologies to be fully realised with due consideration for the human dimension
- (VII) Coordinate global interoperability efforts and promote European R&I results in relevant open international fora and
- (VIII) Ensuring the necessary funding for these activities in accordance with the ATM Master Plan and SRIA.

4.4.3. Priority setting and level of directionality required

Europe's common vision to replace the current fragmented national systems with a new collaborative platform at EU level is the Digital European Sky defined in the European ATM Master Plan. The Master Plan is the basis on which the strategic research and innovation agenda (SRIA) for the future R&I programme is built, as it has the support of the ATM stakeholder community and of the Member States. It is critical that stakeholders with strategic roles in the sector remain committed to the partnership. Industry should be ready to continue to improve the performance, cost and reliability of solutions. A partnership naturally encourages the cooperation between stakeholders who are otherwise competitors, working together on the basis of a jointly agreed multi-annual plan addressing common goals for the sector.

A first draft of the SRIA was developed with the full involvement of the members of the current SESAR JU, as well as with potential future partners of the new partnership. The process for finalising it will include a public survey to solicit input and comments from the wider ATM stakeholder community, including new entrants.

Less mature solutions should also continue to be supported. Political support from both the Member States and the Union is needed and often the technological solutions (e.g. for safety) are not necessarily economically viable.

To conclude, the level of directionality should be as high as possible for the initiative to reach its expected impacts. The strategic vision should be shared and implemented as much as possible by the key stakeholders along the whole value chain.

4.4.4. Coherence needed with the external environment

As the infrastructure is shared but still fragmented across all EU Member States, often used by a wide (and ever widening due the potential offered by drones) range of both civil and

military use cases, ATM modernisation should be addressed through close collaboration frameworks with other programmes and initiatives to create synergies and limit duplications. Regarding other initiatives such as (but not limited to) Clean Aviation, it is crucial to share views on the ways to integrate the next generation of aircraft that will be cleaner and quieter and ideally to share a common vision to define where to concentrate efforts. Joint or coordinated calls, including their funding and management, would be the next step to ensure full coherence with other initiative's agendas. Beyond air transport ATM R&I should also ensure that it remains coherent with wider R&I initiatives such as:

- Multi-modal transport (such as candidate partnerships related to road, waterborne and rail transport), as ATM systems need to be aware of performance requirements to support multi-modal transport. For example, to ensure inter modal connections can be made by passengers.
- Digital technologies and Climate Science, where ATM needs to be aware of and adapt to the ATM context the technologies for data manipulation and distribution, cyber security, advanced decision making including big data, artificial intelligence and findings and recommendations on climate change.
- Similar R&I programmes in other World regions, in particular the US or China to ensure the global convergence of technologies, standards and ultimately of the operational environment for the airspace users.
- Promote synergies with programmes at EU, national and regional level (e.g. Connected Europe Facility Programme, Digital Europe Programme) to ensure deployment.

Due to its interlinkage with other sectors and research initiatives, the initiative should be set up in close collaboration with other programmes and initiatives to create synergies and limit duplications. It is essential to ensure that the governance of the initiative appropriately addresses these collaborations to improve administrative procedures. An initiative able to provide support to potential project partners could also simplify the administration, in line with the recommendations of the Interim Evaluation for the initiative^[1].

Other key elements related to the framework conditions will play a role in the ability of the initiative to reach its objectives. This concerns in particular the next steps after R&I activities, namely the wider scale (beyond a critical mass of early mover) market uptake of R&I results across Europe (including e.g. standards evolution). To ensure supportive framework conditions, the initiative should ensure close collaboration and engagement with end users, citizen, policy makers and regulators as a central step in spurring the setting up of suitable regulatory frameworks and the establishment of market uptake conditions. Furthermore there is a need to link with other crucial funding and financing mechanisms (CEF in particular) to create synergies and realise the targeted impact for the partnership. Beyond CEF complementarity with other funds such as (but not limited) the European Green Deal Investment Plan (EGDIP) and the European Defence Fund (EDF) as well as risk capital players should be sought to finance scaling up activities to the market.

<https://ec.europa.eu/research/evaluations/pdf/sesar2020.pdf>

5. WHAT ARE THE AVAILABLE POLICY OPTIONS?

This section describes the specific functionalities that could be provided under the baseline scenario of traditional calls as well as the different options of different types of European partnerships

5.1. What is the baseline from which options are assessed?

The baseline scenario used in this impact assessment is a situation without a Partnership building on traditional calls of Horizon Europe. Given that there is an existing Partnership as well as other funding sources in the area, these will continue generating effects even if there is no new Partnership. In particular it is expected that these already existing initiatives will still have an impact in the coming years. This is taken into account in the effectiveness assessment.

In parallel, the baseline situation means that the current implementation structure of the Article 187 would be closed, which entails winding down and social discontinuation costs. There would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is taken into account in the efficiency assessment

Table 4: Key characteristics of the baseline situation, i.e. Horizon Europe calls

	Functionalities of the option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • The Commission would need to consult extensively with a wide range of stakeholders to translate the existing European ATM Master Plan (covering priorities for both R&I and implementation) into a more detailed R&I plan (a Strategic Research and Innovation Agenda (SRIA) and an annual work programme. • A well-defined process would be needed to ensure that the programme committees were properly informed about ATM R&I priorities, including the need for key demonstration programmes. • The specification of calls over the period of the Framework Programme will reflect the need for an evolving profile of participation, with different consortia forming at different stages to take different types of activity forward.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • Implementation would be limited to running R&I projects relying on standard infrastructure underpinning the open calls procedure, drawing on resources of relevant executive agencies and Commission IT systems. • Without proper coordination there is a risk for delays in transitioning the R&I results into deployment. Moreover, due to the complexity, fragmentation and safety critical nature of ATM, this could be challenging also from a scientific perspective. • Administrative costs for the European Commission would be significantly reduced, but potential impacts, coverage and contribution to Union's policies are reduced as the full range of activities needed (see section 4.4.2.) could not be covered • Calls for proposals would be published in the work programmes of Horizon Europe. • Transparency and open publication of results would ensure their broad availability to all interested parties. • Dissemination of knowledge among participants would only possibly take place within the consortia answering the calls. • The individual consortia may have limited incentive to initiate and maintain the coordination activities with standardisation bodies.

Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • Organising and coordinating at strategic level the European ATM Master Planning activities to ensure alignment between the R&I agenda and results into changes to the ATM infrastructure will be very difficult and may lead to reduced market uptake and a further lengthening of the innovation cycles in ATM. • Annual Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from representatives of all relevant stakeholders. • Specification of calls for activity at higher TRLs, particularly demonstration programmes, would need substantial input from industry. • Selection of high TRL projects would require provision of external and independent expert advice to the Commission. • Commission input into specification of calls would help to ensure alignment with overarching policy objectives.
Securing leveraging effects (additionality)	<ul style="list-style-type: none"> • Progress of R&I effort would depend largely on EU funding, with no expectation of (significant) commitment and contribution from the side of the industry. • Demonstration programmes would require significant in-kind support and collaboration from industry, but there is no certainty that critical mass could be reached.
Key differences compared to the current situation	<ul style="list-style-type: none"> • The long-term commitment to a common vision by a wide range of stakeholders would be lost at a time when the sector has been severely affected by the COVID-19 crisis. • The position of Europe as a world leader in technology supporting aviation infrastructure may be lost to emerging challenges from e.g. China • The leverage effect achieved today by the Union’s intervention would be lost • No additional synchronised investments by the industry • The system would revert to a more national approach, undermining the achievements at EU level over the last 12 years. • Integration into the SESAR innovation cycle and links with industrialisation and deployment would be weakened

5.2. Description of the policy options

Table 5: Key characteristics of Option 1 – Co-Programmed European Partnership

	Implications of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • The option would enable participation of key private stakeholders committed to support the development and implementation of the programme of research and innovation activities (based on a joint strategic R&I agenda). • The direct participation of inter-governmental organisations and agencies who have already expressed interest to participate (Eurocontrol, European Space Agency) will be more difficult to secure compared to option 2. • It would need to consult with a wide range of stakeholders to ensure that the R&I agenda, and ultimately the work programme, is aligned with the broader industry and market needs. • Usually run by one or several associations or consortia, it is very flexible for new partners to join over time (e.g. to support new areas of activity in response to emerging results and changing priorities)
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • Implementation of EU funding would rely on standard administrative infrastructure underpinning the open calls procedure, drawing on resources of relevant executive agencies and Commission IT systems. The full range of activities planned could be implemented. • Integrating and transferring the outcomes of R&I results into day-to-day operations while keeping a focus on accelerating market uptake and shortening innovation cycles as defined in the European ATM Master Plan will require to put in place complex inter-institutional arrangements at EU level as well as with inter-governmental organisations such as EUROCONTROL and the wider industry to leverage and recognise the results delivered by the coordinating association/consortium. • Calls for proposals would be published in the work programmes of Horizon Europe. • Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from the various partners to achieve an appropriate balance of activities. • Partners implement their additional activities separately. A coordinating association/consortium would provide back-office that provides support to facilitate the coordination of activities (e.g. organising meetings, events, drafting inputs, papers, etc.)

	<ul style="list-style-type: none"> • By using the HE standard implementation, calls are more transparent and accessible for applicants.
Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • The partnership would be responsible for ensuring that priorities for calls were specified in line with R&I priorities across all TRL levels. • R&I activity would be likely to focus on the medium-term needs of the industry. • The partnership would be responsible for ensuring that priorities for calls were specified in line with RD&I priorities, including demonstration projects • Programme Committee has an important role in ensuring alignment with overarching policy objectives and coordination with related programmes. • Coordination of global interoperability efforts and the promotion of European R&I results in relevant international fora (such as ICAO) will be difficult to achieve
Securing leveraging effects (additionality)	<ul style="list-style-type: none"> • Aspirations for partner contributions would be clearly defined in the MoU. • Commitments from the industry are expected to match the Union contribution (most likely only in-kind contributions). • Expected in-kind contributions from the private sector would be identified in the work programme. • The commitment of Eurocontrol to allocate financial resources to the initiative, matching the Union's contribution in value is at risk.
Key differences compared to the current situation	<ul style="list-style-type: none"> • No Union body to coordinate all ATM research & innovation in Europe and to provide policy and technical assistance to the Commission. • Fewer mechanisms to project the Union's policy priorities versus the industry's individual goals. • Limited/reduced participation from Eurocontrol. • Limited ability to boost the European industry globally through international agreements and the setting of global standards. • Limited ability to coordinate and reinforce the Union's scientific capabilities

Table 6: Key characteristics of Option 2 – Institutionalised European Partnership (Article 187 TFEU)

	Implications of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • This option would enable participation of major key stakeholders (see section 4.4.1) through a clearly defined membership structure, including the participation of Eurocontrol or the European Space Agency. • It will be more difficult for smaller players, like SMEs and academia to be able to join as full members. • It would provide a platform for consulting stakeholders on R&I priorities and the work programme, ensuring that they were aligned with ATM in particular and aviation in general. • Participation would be less flexible than under other options, but it might nevertheless be possible to change the profile of participation over time, with new partners joining to support new areas of activity in response emerging results and changing priorities.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • A dedicated administrative structure would be established to coordinate the full range of activities defined in section 4.4.2, to manage implementation and report on the results (with administrative expenditure limited to up to 5% of the budget). • Calls for proposals would be published broadly in the Funding & Tenders Portal by the administrative structure. • Dissemination of knowledge and share of practices would happen among the stakeholders of the community, with potential diffusion activities managed by the partnership structure. • As an EU body, upon a mandate from the Commission, this type of partnership can represent the EU at international bodies such as ICAO and with international governments – supporting the coherence and interoperability of ATM systems world-wide.
Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • Based on a joint Agenda, this form of partnership allows the development of a work programme fully in line with the R&I priorities identified by the industry to fulfil the European policy needs, combining activities across low and high TRLs and in different areas. • The work programme would build a synergy between the Union's policy objectives and the

	<p>technical capabilities of the industry.</p> <ul style="list-style-type: none"> • Commission participation in the partnership governance arrangements and approval of the work programme would help to ensure alignment with overarching policy objectives and enable integration with other programmes.
Securing leveraging effects (additionality)	<ul style="list-style-type: none"> • Funding requirements would be clearly defined at the outset, with the private sector and inter-governmental organisation partners (EUROCONTROL) more leverage than a simple matching of Union funding.
Key differences compared to the current situation	<ul style="list-style-type: none"> • This option would continue and build on the achievements of the current partnership, preserving the good practices and improving any remaining weak points. • Continued engagement of all stakeholders in the sector ensures that the sector maintains its status and competitiveness as world innovation leader. • The synchronised investments by the industry will be maintained. • Links with the industrialisation and deployment phase of the SESAR project will be strengthened, by reinforcing the JU's role as facilitator for the progress of SESAR solutions through standardisation and certification processes, all the way to supporting market uptake for a critical mass of early movers. • Stronger participation of EASA, the standardisation bodies, the Member States and new entrants in the governance

5.3. Options discarded at an early stage

The Co-funded Partnership and an Institutionalised Partnership created under Article 185 of the TFEU are not considered beneficial for the integrated Air Traffic Management initiative.

In the public-public partnership options (co-funded or Art. 185), the partners do not include private sector companies or private research organisations and instead include only public authorities who fund research (or governmental research organisations) and other public authorities at the core of the consortium. These types of partnerships rely on pooling and/or coordinating national programmes and policies with Union policies and investments, to help overcome fragmentation. Due to the limited existence of national R&I programmes in the area of ATM and the lack of relevant public bodies, there is little interest for Member States and their agencies to be involved in such partnerships.

Nevertheless, Member States are keen to be active in ATM R&I but through the national ATM service providers (funded by the airspace users) rather than the public purse.

Furthermore, the ATM R&I programme requires strong consensus to ensure that the results are directly deployable within the emerging architecture and are acceptable to the professionals that operate the system. This is best achieved by air navigation service providers working closely with the manufacturers and building on inputs received from the broad range of stakeholders in the ATM community.

The options dedicated to public-public partnerships are therefore not considered viable and not considered further.

6. HOW DO THE DIFFERENT POLICY OPTIONS COMPARE?

Based on the objectives pursued by the initiative and the key functionalities identified to be able to achieve them, each option for implementation is assessed in terms of effectiveness, efficiency and coherence compared to the baseline scenario of traditional calls. The analysis is primarily based on the degree to which the different options would cater for the key needed

functionalities. All options are compared to the baseline situation of traditional calls, which is thus consistently scored at 0 to serve as reference point.

6.1. Effectiveness

To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like, differentiating between scientific, economic/technological, and societal (including environmental) impacts. This section considers to which extent the different policy options would allow delivering these expected impacts – confronting what is needed (functionalities) with what each form of implementation can provide in practice. The assessments in this section set the basis for the comprehensive comparative assessment of all retained options against all dimensions in Section 6.4, based on a scoring system¹⁰⁹.

Scientific impacts

A) Strengthening the EU’s scientific capabilities and improving the scientific knowledge in ATM can be achieved by continuing to support and reinforce an ATM R&I ecosystem that is capable of rapidly developing and validating modern technologies that build on the upcoming digital transformation elements, such as automation, AI, big data and cyber-security. Due to the specific challenges related to ATM infrastructure modernisation (safety critical, significantly regulated), without a long-term focus and commitment from both the research and the industry communities across multiple research disciplines, Europe’s ATM sector will not be able to adapt quickly enough to help the aviation sector to grow out of the COVID-19 crisis more sustainable and smart.

The baseline option (open calls) is flexible to adapt to the changing needs of the sector, in particular concerning rapidly emerging technologies, such as drones. This option could manage fundamental/exploratory R&I activities well enough (and could be complementary to partnerships) if there was a centralised research agenda. However, this option does not provide an effective EU (and global) coordination platform for science transfer to advance the application of exploratory research results with industry to find common solutions to specific questions of a concrete nature.

Option 1 could deliver more impact than the baseline option, in particular concerning industrial research at higher TRL levels, where large players investing in a partnership could lead to a strong push for breakthrough technologies. SMEs and academia, as smaller stakeholders who find it harder to join the partnership may have a reduced role. The option scores **good** compared to the baseline (+).

Option 2 would ensure long-term coordination of the R&I programme to guarantee that the necessary scientific breakthroughs are prioritised to support long term evolution of ATM including adaptation of advanced digital solutions to enable automation. Whilst, the core membership may naturally prioritise short-term solutions that do not fully embrace the innovation agenda, the long term aim of an Institutionalised Partnership will ensure a balance between developing advanced solutions and maturing deployment-ready solutions¹¹⁰. Its score would therefore be **high** compared to the baseline (++)).

¹⁰⁹ A more in depth and detailed analysis of each policy option is provided in Technopolis Group Study (2020)

¹¹⁰ As stated in interviews with stakeholders from both research and industry institutions available at <https://www.sesarju.eu/interviews> and notably the interviews titled “The new face of aviation research” as well as “Nothing ‘elementary’ about air traffic management research, says SESAR researcher”

B) Enhance capacity among next generation aviation professionals. The modernisation of ATM will have a fundamental effect on the professionals employed by the aviation community, including traffic controllers and engineers. It is thus essential to involve universities who train the next generations of experts in the R&I programme **to secure a steady flow of competent professionals to the sector.**

The baseline option provides for a dissemination platform allowing knowledge and ideas sharing, mostly in academic settings (e.g. conferences). The results are loosely linked with the industry. As work and coordination of various topics is linked to the duration of grants, it is unlikely that research results would be followed into high level education programmes, having thus a limited effect on upskilling for both researchers and aviation professionals.

Option 1: As long as the members of the partnership see the added value for strong sharing and knowledge transfers, there is potential to build strong relationships with academia and innovative SMEs or with other ATM R&I programmes beyond Europe. This option scores **good** compared to the baseline. A more stable structure improves the focus and continuity of links with educational programmes.

Similar to Option 1, an institutionalised body (**Option 2**) implementing all Union research activities in the sector can facilitate a steady flow of exchanges and cooperation activities with educational actors. The current JU has a good tradition of organising targeted events¹¹¹ that facilitate knowledge dissemination and transfer. This is a good practice that has proven valuable in the past. This option also scores **good** compared to the baseline (+).

Stakeholders view an institutional partnership for ATM as the best option to address the fragmented and conservative industry, which, without coordination will engage in stand alone research projects and lack of research continuity that will not help address the challenging tasks of R&I and deployment.

ATM has specific challenges that require research coordination, expertise and resources from the whole value chain including key actors. Solutions that are still under development and future challenges are best address by a dedicated institutional ATM partnership.

To ensure better transition through the R&I pipeline and acceleration of development processes. Exploratory research is essential to feed the SESAR innovation pipeline and must be reinforced whilst accepting uncertainty to allow innovation.

Stakeholders stated that in their view the initiative for integrated ATM is very relevant (44% of respondents) or relevant (24%) to deliver the impact on the education of the next generation of aviation professionals and encouragement of diversity and inclusion.

Economic/Technological impacts

C) An accelerated delivery of innovative ATM solutions needed for aircraft operations that help improve the flexibility of the European ATM network and systems allows for the **handling of additional flights and thus facilitating economic recovery and growth in the air transport sector.** It also increases the efficiency of the network, thereby reducing the environmental impact of aviation.

¹¹¹ E.g. SESAR Innovation days, Young Scientist Awards or Hackatons. See examples including stakeholder interviews at: <https://www.sesarju.eu/news/young-talent-celebrated-2019-sesar-innovation-days> as well as an article covering the Hackathon through the eyes of the winners <https://www.sesarju.eu/news/innovation-aviation-digital-sky-challenge-through-eyes-winners>

The baseline option has the potential to support the development of innovative concepts, without a coordinated approach of the industry there is little potential for industrialisation and deployment to make significant impacts on the real operations.

Option 1 would bring together a broader community of private stakeholders than the baseline, who coordinate their work to deliver R&I according to Union priorities. The limited role of the Union in managing interdependencies within the partnership could hamper the overall success if the industry's business models and priorities take precedence on what is delivered. This option scores **good** compared to the baseline (+).

Supported by long-term commitment from the industry, **Option 2** would build on the experience of the current JU who has built a successful Large Scale Demonstrations platform and accelerated the innovation pipeline, reducing the duration needed for a technical solution to reach the market¹¹². As a Union body coordinating the ATM research programme, the institutional partnership would be able to take an independent position towards diverse and diverging industry interests, pushing for Union priorities in the interest of European citizens and businesses¹¹³. This option scores **high** compared to the baseline (++).

D) Safely and efficiently integrating drones and drones traffic management systems with the ATM systems facilitates **the ramp up of drones-related economic activities**, opening up the market for new types of drones services operators and drones traffic management service providers¹¹⁴.

The **baseline option** can support the innovation required to integrate drones into ATM systems, enabling new entrants to be involved without the overhead of fully committing to a partnership. However, the complex nature of the European airspace requires new solutions that are interoperable with an ever-changing ATM system and architecture. Without a strong coordination at EU level, open calls are unlikely to generate the momentum that would secure the interoperability needed to ramp up drones activities in the coming years¹¹⁵.

Option 1 would see an improvement compared to the baseline, as a coordinated industry approach where drones manufacturers and drones service providers play an active role would generate the appropriate levels of investments and technological progress to put in place a European drones' traffic management system that would in turn facilitate the ramp up of drones economic activities in the next decade. This option scores **high** compared to the baseline (++).

¹¹² As affirmed comprehensively in interviews with stakeholders from both research and industry institutions available at <https://www.sesarju.eu/interviews>

¹¹³ See Annex 2 Synopsis report on the stakeholder consultation

¹¹⁴ According to the European Drones Outlook Study (SESAR Joint Undertaking 2016) by 2050, it is estimated that there will be some 7 million consumer leisure drones in operation across Europe, including a fleet of 400 000 drones offering important services across the agricultural, energy, e-commerce, transport as well as public sectors. With an estimated value of EUR 15 billion annually, this market represents a huge potential for Europe and its global competitiveness. The full report is available at: <https://www.sesarju.eu/index.php/newsroom/all-news/europe-needs-prepare-drone-market-boom-says-new-study>

¹¹⁵ According to the European Drones Outlook Study (SESAR Joint Undertaking 2016) building a designated 'home' for the drone traffic management R&D at European level has extended benefits related to the creation of a single market.

Similar to Option 1, **Option 2** would be in a much better position than the baseline to put in place the framework necessary to ramp up the drones-related activities in the EU. The advantage of Option 2 is that it would build on the experience of the current JU who has already 4 years of experience with these activities, having already developed a European blueprint for U-space drones' traffic management systems¹¹⁶ and having carried out already multiple drones services demonstration projects, under Horizon 2020, CEF and EP Pilot Projects funding¹¹⁷. The option scores **high** compared to the baseline (++).

E) A Europe-wide agreed ATM architecture relying on inter-operable ATM solutions standardised and certified at European level will give Europe a strong voice at international level, where European technologies should remain the backbone of global ATM modernisation plans coordinated by ICAO. This should boost the **EU industry globally by enabling international agreements and contracts**.

The **baseline option** could provide for call provisions requiring beneficiaries to participate and support standardisation activities. This option would lack the access to global level fora and would have limited capacity to promote European technologies and standards internationally.

Option 1 would be in a better position than the baseline to support the market uptake of technical solutions. However, as an industry body (as opposed to a Union body), the partnership would have no access to decision making bodies at ICAO level and would wield less influence overseas with ATM organisations which tend to have government status. This option scores **good** compared to the baseline. (+)

Option 2 brings the added value of having a Union body responsible for coordinating activities and representing the Union (upon a mandate received from the Commission, as it is currently the case with the SESAR JU) and stakeholders involved in international negotiations and ATM standard setting activities. This option scores **high** compared to the baseline (++)

Stakeholders' opinion (based on the Open public consultation)

Baseline scenario of open calls is not an alternative to increase efficiency and speed up development or implementation of the Single European Sky of which EU economy and travelling public are the beneficiaries.

An institutional partnership for ATM is required due to the fragmented and conservative industry that without coordination will lead to stand alone research projects and lack of research continuity that will not help address the challenging tasks of R&I and deployment.

Take a holistic approach that includes an adapted regulatory framework, operational aspects and development and maturation of the critical enabling technologies. Standardisation, and implementation are crucial to develop an interoperable, scalable and harmonised EU ATM system that safe, efficient, sustainable, connected, airspace and air transport.

¹¹⁶ Drafted by the SESAR Joint Undertaking, the U-space blueprint sets out the vision for the U-space, which aims to enable complex drone operations with a high degree of automation to happen in all types of operational environments, particularly in an urban context. When fully deployed, a wide range of drone missions that are currently being restricted will be possible thanks to a sustainable and robust European ecosystem that is globally interoperable. More information at: <https://www.sesarju.eu/u-space-blueprint>

¹¹⁷ SESAR U-space projects results published at <https://www.sesarju.eu/news/sesar-u-space-projects-results-published>

ATM Modernisation is a global issue and the partnership should keep a global mindset pushing towards harmonisation without leaving behind the R&I European focus. It should encourage networking and cooperation to promote EU standards at a global level in order to implement solutions that can be leveraged in terms of global industry. Solutions should be in line with ICAO recommendations and EASA regulations, especially for drones.

Diverging interests from the industry and service providers should not influence the research and development priorities but it should be kept customer and result driven. The focus should be on operational performance benefits for the whole network and society (including passengers).

The momentum, context and success of the SESAR Joint Undertaking should be followed up. The participation stability, resilience and experience acquired in the last 10 years by SESAR's systematic approach are required in order to follow the learning curve that will allow to address the future challenges.

Member States indicate strong agreement with the proposed objectives at short, medium and long term (82%) and the expected scientific, economic and societal impacts at European level (82%), with the remaining ones remaining neutral. 71% of countries consider the impacts very or somewhat relevant in the national context.

Societal impacts (including environment)

F) The technological progress resulting from this initiative would make the European airspace significantly more efficient and environmentally than today where 5-10% of air transport's CO₂ emissions could be avoided due to inefficiencies in the ATM infrastructure¹¹⁸.

With the European Green Deal driving the policy priorities, the **baseline option** would see significant funding allocated to open calls aimed at addressing the environmental challenges. However, without a coordinated approach across the whole industry, locally developed solutions would have limited impact on supporting end-to-end optimisation of flight paths.

Option 1 would improve the focus of R&I activities along the current Commission priorities. However, investment in climate research is expensive. However, conflicts of interest between industry interests may be difficult to effectively handle where there is no tangible direct benefits to the industry, leading to a risk of reduced innovation and delays in the delivery of sustainable solutions. This options scores **good** compared to the baseline (+).

Under **Option 2**, a Union Body would steer a common approach by all stakeholders in ATM and would be able to focus on the necessary ATM modernisation to enable environmental goals that can best be achieved by enabling aircraft to fly on their optimum 4D trajectory in the climb, on-route and descent phases of flight - the optimum horizontal path from departure to destination flown at the most fuel efficient flight level. This can only be achieved by compressive and wide coordination with all stakeholders that have been deeply impacted by the COVID 19 crisis (including intergovernmental organisations such as EUROCONTROL that have significant expertise in the domain) as defined in section 4.4.1. The Union body would ensure that the environmental priority is maintained as the R&I results require performance trade-offs (i.e. environment versus cost-efficiency - a trajectory with low environmental footprint is enabled by sufficient ATM capacity, which increases the ATM provision costs).

¹¹⁸ European ATM Mater Plan, Edition 2020, Figure 10

In addition, as previously done with the SESAR JU, the Union body would be tasked by the Commission to develop technical support for EU Regulations in the sector, monitor the coherence between the results of R&I and the EU ATM Master Plan and the Single European Sky policy.

This is the Option that would best support ATM modernisation with the necessary coordination and acceleration leading to the timely environmental optimisation of ATM, hence this option scores **high** compared to the baseline (++).

G) The expected societal impacts are reduced **travel times, improved predictability, reduced delays and lower costs**. This improves both the passenger experience¹¹⁹ and business opportunities.

The **baseline option** would facilitate the involvement of innovative SMEs. However, similar to the environmental impact, the lack of a mechanism to manage interdependencies between emerging solutions has a potential negative impact on the overall coherence of the R&I programme and may not lead to solutions needed for the emerging ATM architecture¹²⁰.

Option 1 would use a coordinated approach to deliver solutions that improve the performance of the system. However, without a strong Union steering in the governance a partnership lead by air navigation service providers and airlines would prioritise solutions benefitting their economic activities, rather than the passenger experience or the interest of the citizen in general. The option scores **good** compared to the baseline (+).

Option 2 provides for a strong role for a Union steering in the governance of the partnership that would ensure that the priorities and activities take into consideration the interests of all stakeholders, including citizens¹²¹. This option scores **high** compared to the baseline (++).

Stakeholders's opinion (based on the Open public consultation)

The need to modernise the existing system through the application of emerging technologies such as digitalisation, automation and big data was a recurrent theme amongst the interviewed and throughout all the categories. Generally, and more specifically airspace users, see as the main challenge addressing environmental sustainability.

Links with Clean Aviation: while distinct partnerships are needed (as stakeholders and processes are different), there should be mechanisms for synergies and cross-fertilization in place as they share objectives - notably lowering emissions - and solutions need to be developed in a consistent way.

Fundamental Rights impacts

None of the above options is expected to impact fundamental rights in the EU or abroad.

Directionality and additionality required

¹¹⁹ ACI Europe publication “SESAR and the digital transformation of Europe’s airports” available at <https://www.sesarju.eu/sites/default/files/documents/reports/SESAR%20and%20the%20digital%20transformation%20of%20europe%20airports.pdf>

¹²⁰ Results from the open calls under previous framework show that a partnership approach was required to support exploitation of the results.

¹²¹ As affirmed comprehensively in interviews with stakeholders from both research and industry institutions available at <https://www.sesarju.eu/interviews>

As regards the level of directionality and additionality required, **the baseline option** would not be able to facilitate the synchronised actions necessary to support policy objectives. Even if this option could ensure partial alignment with EU strategies, it would not be effective enough to significantly contribute to achieving them.

With the ability to prepare and implement a medium term plan, **Option 1** could ensure compliance with the Union and Member States strategies. However, in the absence of a strong EU involvement in the partnership, it would be more difficult to steer the industry-led partnership towards achieving the Union’s policy priorities linked to the digital transformation of ATM or the ambitious environmental targets of 2030 and 2050.

A long-term vision and strategy for ATM is essential for successfully transforming the sector. By involving research organisations, all relevant types of economic actors and the public sector, **Option 2** is considered as the most appropriate since it ensures a long-term commitment. Integrating the Strategic R&I Agenda into a broader spectrum is also essential. Option 2 will ensure a coherent approach across the whole ATM innovation cycle, from R&I to market uptake, addressing in particular the “valley of death” challenge of industrialisation.

Table 7 summarises the scores assigned for each policy option, based upon the assessments above, as well as taking into account the support expressed by the different stakeholders.

Table 7: Overview of the options’ effectiveness compared to the baseline

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Institutionalised Article 187 TFEU
Scientific impact			
New scientific knowledge and reinforcement of EU scientific capabilities	0	+	++
Enhanced capacity among the next generation aviation professionals	0	+	+
Economic/technological impact			
Ability to handle additional flights enabling growth in air transport	0	+	++
Enable new economic activity based on drones	0	++	++
Boost EU industry globally through international agreements and the setting of global standards	0	+	++
Societal impact			
Reducing aviation noise and gas emissions	0	+	++
Improve customer experience and business opportunities by reducing travel time, improving predictability	0	+	++

Notes: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.2. Efficiency

In order to compare the policy options consistently in terms of their efficiency, a standard cost model was developed for the external study supporting the impact assessment for the set of candidate Institutionalised Partnerships. The model and the underlying assumptions and analyses are set out in the Common Part of this impact assessment, Section 2.3.2 and in the Methodology Annex 4. A dedicated Annex 3 also provides more information on who is affected and how by this specific initiative in line with the Better Regulation framework. The scores related to the costs set out in this context allow for a “value for money” analysis (cost-effectiveness) in the final scorecard analysis in Section 6.4.

In addition, for this specific initiative under the baseline scenario of traditional calls, there would be winding down (estimated at EUR 500K) and social discontinuation costs for the existing implementation structure of the current Article 187 initiative. There would also be longer term financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. These can be estimated at EUR 4 million per year of operation (including Commission supervision costs saved). Overall it is estimated that the overall longer term cost savings from using traditional calls instead of an existing Article 187 initiative would thus considerably exceed the costs incurred for winding down operations. This overall situation is set as the starting point for the comparison of options. The score of this baseline scenario (traditional Horizon Europe calls) is set to 0 to be used as a reference point.

On this basis, the scores for the costs of the different options range from a value of 0, in case an option does not entail any additional costs compared to the baseline, to a score of (-) when an option introduces limited additional costs when compared to the baseline and a score of (-)(-) when substantial additional costs are expected in comparison with the baseline. In case the scores are lower than for the baseline scenario, (+) and (+)(+) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. Indeed, in terms of cost-efficiency, the Co-Programmed Partnership (Option 1) is 2 percentage points more efficient than the baseline; and an Article 187 Partnership is 2 percentage points less cost-efficient than the baseline. A score of + is therefore assigned for **cost-efficiency** to the Co-Programmed options and a score of (-) for the Institutionalised Partnership policy option, as illustrated in Table 8 below¹²².

More specifically for the ATM partnership, building on the assumptions outlined in Figure 4 of Annex 4 and the known real costs, e.g. from the current SESAR JU implementation, the additional costs compared to the baseline are about 6-7% of the Union's contribution. When considering the fact that over 60% of these administrative costs are covered by private and inter-governmental partners (i.e. Eurocontrol), re-establishing the JU is roughly similarly efficient to the baseline scenario (96%-97%), and only one percentage point behind in efficiency to the co-programmed partnership. Considering the fact that the Art 187 initiative has the highest ability to deliver the highest expected impacts, it delivers the best value for the Union budget investment.

Additional assumptions regarding these costs:

- The potential for the crowding-in effects for the industry have been taken into account when assessing the effectiveness of the policy options, above.
- For the overall administrative, operational and coordination costs, in the case of a partnership the industry (including EUROCONTROL for Art 187 only and other industry partners) would contribute to the running costs of the partnership, which significantly reduces the costs to the Union for this partnership. Based on experience to-date with the JU it is assumed that the industry partners other than the EU could

¹²² The baseline (traditional calls) is scored 0, as explained above.

together contribute to approximately 60% of the running costs, thus minimising the additional cost of an Article 187 option for the EU.

- The above considerations on cost-efficiency do not take account of the additional leverage created by the full involvement of EUROCONTROL in the ATM partnership: indeed, in the case of SESAR and an Article 187 option only, EUROCONTROL and the industry would each match funding for the EU budget, leading to a gross leveraging ratio of up to 1:2,5, as shown in Annex 4. This additional leverage could not be guaranteed for the Baseline option and would only be partial (not including EUROCONTROL who would be a beneficiary) for the Co-programmed option.
- This analysis is based on costs only but should also consider a number of positive qualitative elements for the Union:
 - The Union has a higher level of control on the use of funds through the application of the Commission’s internal control framework, through regular oversight by the Commission and through the direct discharge procedure by the European Parliament;
 - the added value in steering the overall activities and setting direction. The costs of setting up a Strategic Research and Innovation agenda are lower when using the currently established partnership as a platform to coordinate the preparation with the industry.

Based on the elements above, once leverage, sharing of running costs and level of control are taken into account, the overall costs are adjusted as follows:

Table 8: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Administrative, operational and coordination costs	0	0	-
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	+	0

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline.

6.3. Coherence

6.3.1. Internal coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with other actions, programmes and initiatives under Horizon Europe, in particular European Partnerships (internal coherence).

Baseline: Horizon Europe calls

Under this option, coherence between activities in the area of ATM R&I with activities under Cluster 5 of Horizon Europe and the other initiatives presented in Figure 1 is ensured by the European Commission. However, exploitation of synergies with other initiatives, including exchanges of knowledge and experience between project teams and stakeholders, would require an additional level of coordination beyond Programme Committees. The Baseline option could easily manage individual R&I activities. However, this option would lack the ability to build the long term strategic collaboration between stakeholders needed to advance rapidly the research results through industrialisation and deployment.

Option 1: Co-Programmed European Partnership

Under the Co-Programmed option, synergies could be exploited more easily than under the baseline option. The European Commission could ensure coordination at the level of research agendas, while the partnership would bring together projects and stakeholders from various initiatives to work together on common problems or tackle common challenges. However, considering the specificities of ATM R&I (outlined previously in sections 1, 2 and 4 in particular), the Co-programmed option does not promote a sufficiently broad community engagement framework outside of project consortia, limiting its ability to establish an effective long-term framework and vision, nor increase cross-sector collaboration. Option 1 could better manage all types of R&I activities thanks to a better agenda setting. However, Option 1 is not considered optimum to address the complex structure of the ATM sector and the broad range of actors. Its score would therefore be **good** compared to the baseline with +.

Option 2: Institutionalised European Partnership under Article 187 TFEU

The Institutionalised Article 187 partnership structure provides clear roles for the European Commission and for the industrial partners and is built on a central coordination layer which can increase the effectiveness of its efforts. Since its management body organises the funding and implementation of projects, the integrated ATM partnership could (together with other institutionalised partnerships) set concrete objectives and lay out a roadmap of activities and projects that can be implemented.

A dedicated body responsible for the development of a long-term strategy and supporting work programmes for ATM R&I makes it easier to ensure that these are fully aligned with relevant strategies and programmes developed by other partnerships and initiatives within the EU research and innovation landscape. Option 2 would manage all TRLs related activities, from fundamental R&D up to market-readiness. Good knowledge management is also an asset under this option - to allow the initiative to adequately assess projects in the selection process, to provide technical assistance where needed and even to challenge the industries in order to increase the speed of development. This would translate into a **high** score compared to the baseline set at ++.

A big majority of stakeholders interviewed highlighted the need to build the link with other initiatives, such as Clean Aviation in order to avoid duplication, to improve coordination and synergies on the topics of automation and environment in aviation.

6.3.2. External coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with their external environment, including EU-level programmes and initiatives beyond the Framework Programme and/or national and international programmes and initiatives, as well as with overarching framework conditions such as Regulations, standardisation, etc.

To achieve the ATM objectives, the proposed partnership needs to create close links with the SESAR deployment mechanism and international initiatives, particularly within ICAO and with other ATM modernisation programmes in USA, Japan and China.

Baseline: Horizon Europe calls

Under this option, some coordination with other Union initiatives is possible at the level of priorities, but coordination at the level of implementation is very limited or even not possible.

This option typically remains focused on EU27 and does not allow the pursuit of an international coherent cooperation strategy, nor does it allow for the involvement of the Member States.

Option 1: Co-Programmed European Partnership

Under this option, the European Commission can contribute to some extent to the coordination with Union non-research initiatives at the level of the strategy. The industry-led partnership would have limited access to international decision making bodies at ICAO level and thus limited influence amongst overseas organisations responsible for ATM, which tend to have government status.

The possible participation of Member States provides the opportunity for coordination with the national programmes and initiatives and the regional clusters. Member States could coordinate with the national and industry efforts to ensure alignment with their own R&D agendas. Score would therefore be good compared to the baseline with +.

Option 2: Institutionalised European Partnership under Article 187 TFEU

This option would establish a strong implementing body for research that closely cooperates with industrial, institutional, national, standardisation & certification actors active at different steps of the SESAR innovation cycle and in particular supporting the SESAR deployment phase, mandated by Commission Regulation¹²³ and supported financially by the Connecting Europe Facility Programme. This option offers the best opportunity to involve Member States to discuss priorities and synergies, which is critical to the success of the initiative.

This option also provides the European ATM research sector with the best mechanisms to cooperate at international level, e.g. setting up a Union body capable of representing the Union (upon a mandate from the Commission) in international fora where global ATM standards and regulations are discussed, such as ICAO. This option would allow the continuation of already existing cooperation agreements on ATM research as the one between SESAR JU and the FAA’s NextGen in the USA who have worked for the last decade on ensuring the interoperability between the European and American systems. This would translate into a high score compared to the baseline with ++.

Throughout all the categories, stakeholders made the strong point that there is a need to build up a partnership which has a body that can steer the R&I coordinating key stakeholders from the whole value chain continuously, to achieve the common EU-wide long-term ATM vision. Thus, they do not consider open calls to be a feasible option.

In interviews, stakeholders with direct participation in the current JU have emphasised that continuing to have strong Union coordinated programme and a partnership/body that is able to take part in ICAO negotiations has given the EU a strong leadership position in ATM globally. This should continue.

Table 9 below, lists the scores assigned for each of the policy options, based upon the assessments above, as well as taking into account the views expressed by the different stakeholders.

Table 9: Overview of the options’ potential for ensuring and maximizing coherence

	Option 0: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
--	--------------------------------	-------------------------	--

¹²³ Commission Implementing Regulation (EU) No 409/2013 on the definition of common projects, the establishment of governance and the identification of incentives supporting the implementation of the European Air Traffic Management Master Plan

	Option 0: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Internal coherence	0	+	++
External coherence	0	+	++

Notes: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.4. Tabular comparison of options and identification of preferred option

Building upon the outcomes of the analysis, this section presents a comparison of the options' 'performance' against the dimensions of effectiveness, efficiency and coherence.

Table 10: Overall scorecard of the policy options for all criteria

	Criteria	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 3: Institutionalised Art. 187
Effectiveness	Scientific impacts			
	New scientific knowledge and reinforcement of EU scientific capabilities	0	+	++
	Enhanced capacity among the next generation aviation professionals	0	+	+
	Economic/technological impacts			
	Ability to handle additional flights enabling growth in air transport	0	+	++
	Enable new economic activity based on drones	0	++	++
	Boosted EU industry globally through international agreements and the setting of global standards	0	+	++
	Societal impacts			
	Reducing aviation noise and gas emissions	0	+	++
Improve customer experience and business opportunities by reducing travel time, improving predictability	0	+	++	
Coherence	Internal coherence	0	+	++
	External coherence	0	+	++
Efficiency	Overall cost	0	0	-
	Adjusted Cost-scoring	0	+	0

Notes: Scores for effectiveness and coherence: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline. Scores for efficiency: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline

Overall the implementation of the **integrated ATM initiative through an institutionalised partnership established under Article 187 of TFEU is the preferred option** as it would best ensure that private and public sectors remain fully engaged in the development and implementation of a long-term strategy for ATM R&I.

When compared to the baseline and Option 1, an institutionalised partnership has the following advantages:

- Maximises the impact of Union funding and the leverage, as EUROCONTROL and industry would each provide matching funding to the EU budget, leading to a gross leveraging ratio of up to 300%.
- Accelerates R&I by harnessing the momentum and knowledge of the current partnership.
- Facilitates the active participation of all relevant ATM stakeholders
- Builds synergies with other partnerships and initiatives within and outside the Climate, Energy and Mobility cluster, with an emphasis of international cooperation on ATM research.
- Overall the marginally increased costs are considered acceptable for the greater likelihood of achieving the significant environmental and economic benefits of timely ATM modernisation.

Box 2 Comparison between the preferred option & the current partnership existing in the area taking into account lessons from past evaluations

What continues	What is different
<ul style="list-style-type: none"> • Art 187 Union Body, with EC and Eurocontrol as founding members. • Blending of funds: Horizon, CEF • Strong link with the single European sky policy & strategic planning at EU level through the European ATM Master Plan. • Members contributing to running costs of the JU • Active role of operational stakeholders in the partnership • High leverage (beyond 200%) 	<ul style="list-style-type: none"> • Focus on breakthrough innovation • Open innovation policy, open calls as basic principle • More coherent life-cycle approach and higher impact of investments due to closer links with industrialisation/ market uptake • Simplified architecture & toolbox • Closer engagement of Member States in the Governance • Better synergies with other Horizon and national initiatives

7. THE PREFERRED OPTION - HOW WILL ACTUAL IMPACTS BE MONITORED AND EVALUATED?

7.1. The preferred option

In Table 12, below, the alignment of the preferred option of Institutionalised European Partnership under Article 187 TFEU with the selection criteria for European Partnerships defined in Annex III of the Horizon Europe Regulation is depicted. Seeing that the design process of the candidate Institutionalised Partnerships is not yet concluded and several of the related topics are still under discussion, the criteria of additionality/directionality and long-term commitment are covered in terms of *expectations* rather than *ex-ante* demonstration.

Table 11: Alignment with the selection criteria for European Partnerships

Criterion	Alignment of the preferred option
-----------	-----------------------------------

Higher level of effectiveness	The Institutionalised Partnership is specifically designed to support pan-EU harmonisation of ATM leading to significant environmental, economic and social benefits. The stronger link to the SES policy is critical to reduce risk with transferring solutions from R&I to deployment and hence increase industry commitment.
Coherence and synergies	The Institutionalised Partnership will support synergies with related R&I in advanced digital solutions reducing the likelihood of the industry developing ATM specific solutions where these are not needed. The Institutionalised Partnership is able to build direct links with the deployment programme, supporting an accelerated handover of results leading to a faster accrual of benefits. The Institutionalised Partnership is also advantageous in its ability to represent the EU at ICAO and other international meetings ensuring that European solutions are embedded in future global plans and standards.
Transparency and openness	Through a drive to promote standards for developed solutions the Institutionalised Partnership will support transparency of results leading to increased exploitation both within the EU and globally. The membership process and types of activity including open calls need to ensure a wider participation than the core membership (particularly of academia and SMEs).
Additionality and directionality	The EU role in the governance of the Institutionalised Partnership is advantageous in ensuring that the modernisation of ATM is driven by policy needs and not slowed down by sometimes diverging national and industrial interests. An institutionalised partnership would be able to set up the appropriate approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level.
Long term commitment	The financial contribution of industry is anticipated to be 66% (33% from EUROCONTROL and 33% from the industry) of the aggregated European Partnership budgetary commitments. These commitments are in line with previous commitments to the existing programme over the last decade.

Feedback on the inception impact assessments:¹²⁴ A big majority of stakeholders (70%) expressed support for establishing an Institutionalized partnership under Art 187.

7.2. Objectives and corresponding monitoring indicators

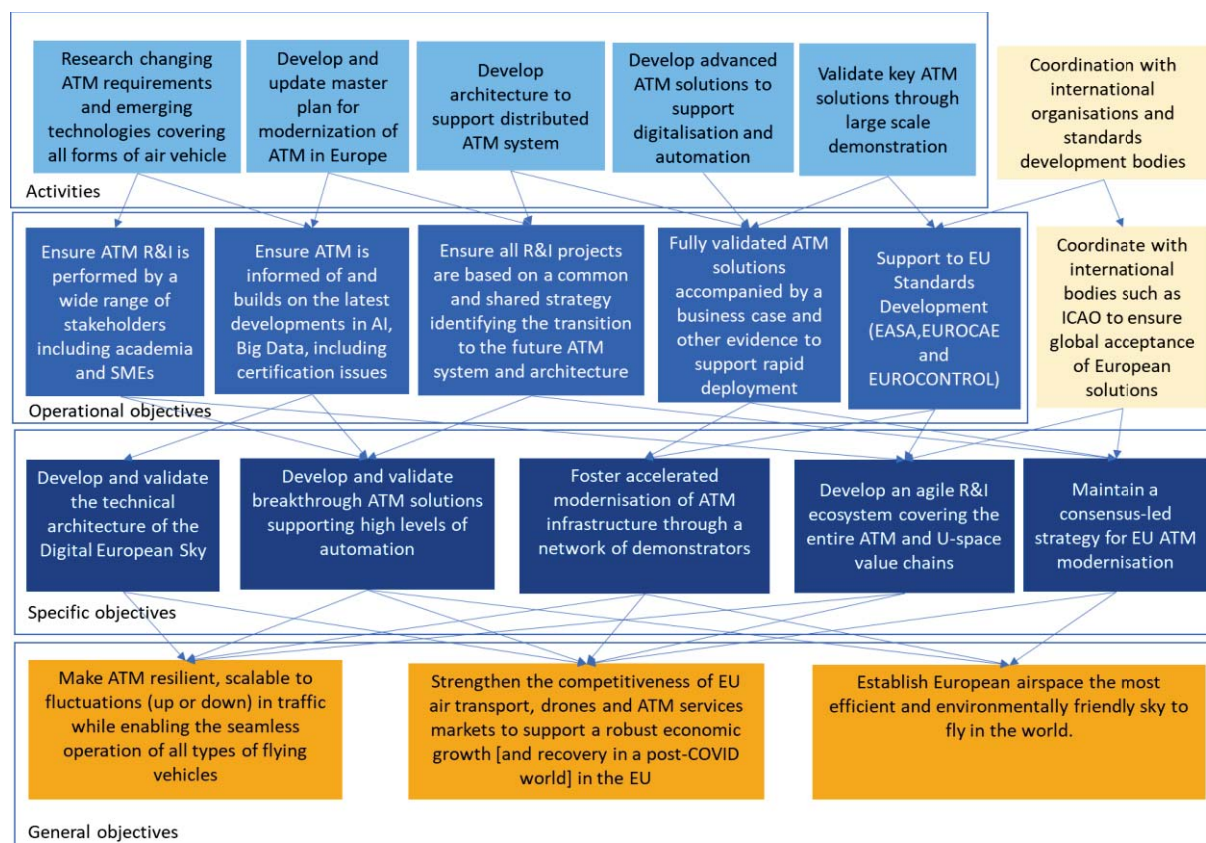

7.2.1. Operational objectives

Several operational objectives have been identified which would enable the partnership to achieve its specific objectives, as shown in Figure 11 below.

The figure also lists a range of actions and activities, going beyond R&I that can be implemented under Horizon Europe (which are highlighted in yellow). This reflects the definition of European Partnerships in the Horizon Europe Regulation as initiatives whereby the Union and its partners “commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”

¹²⁴ The European Commission received 28 responses to the inception impact assessment for integrated ATM. The responses are aligned with the stakeholder responses to the open public consultation and the interviews performed for this report. Therefore, we did not refer to this feedback in the report.

Figure 13: Operational objectives of the initiative

7.2.1. Monitoring indicators

In addition to Key Impact Pathways indicators set centrally in the Regulation of Horizon Europe, additional monitoring indicators have been identified to enable the tracking of progress of the partnership towards meeting its objectives. These are shown in Table 12.

The societal impact and performance of ATM in Europe is currently measured by the Performance Review Body established by the European Commission. This body could be used to monitor the success of the R&I programme in terms of actual operational performance of solutions. Current metrics are limited and could be improved:

- For environmental impact, the current metric could be extended to include the full trajectory (the current metric only measures horizontal efficiency in the cruise phase)¹²⁵.
- The current performance metrics cover safety, capacity (through measurement of delay) and cost-efficiency. This could be extended to include passenger centric measures that better reflect the value of improvements to EU citizens¹²⁶.

Table 12: Monitoring indicators in addition to the Horizon Europe key impact pathway indicators

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
Scientific impact			

¹²⁵ See for example: <https://www.nats.aero/environment/3di/>

¹²⁶ Passenger-Oriented Enhanced Metrics, A. Cook, G. Tanner, S. Cristóbal and M. Zanin, SESAR Innovation Days 2012.

New scientific knowledge and reinforcement of EU scientific capabilities	Number of ATM solutions reaching TRL2	Number of ATM solutions reaching TRL4	Number of ATM solutions reaching TRL6
Enhanced capacity among the next generation aviation professionals fostering diversity and inclusion	Number of researchers involved in upskilling (training, mentoring/coaching, mobility and access to R&I infrastructures)	Number and share of upskilled FP researchers with increased individual impact in ATM	Number and share of upskilled FP researchers with improved working conditions, including researchers' salaries
Technological / economic impact			
Accelerated delivery of innovative solutions into operations	Number of innovative ATM solutions developed	Number of innovative ATM solutions demonstrated	Creation, growth & market shares of companies having developed FP innovations
Enable new economic activity based on drones	Number of innovative U-space solutions developed	Number of innovative U-space solutions demonstrated	Creation, growth & market shares of companies having developed FP innovations
Enable European industry competitiveness based on international agreements and EU/global standards	Number of standards identified as being required	Number of standards initiated	Number of standards published
Societal impact			
Reducing aviation noise and gas emissions	Planned capability of ATM solutions to reduce CO ₂ emissions per flight	Validated capability of delivered solutions to reduce CO ₂ emissions per flight	Measured reduction in CO ₂ emissions per flight during operations
Improve customer experience and business opportunities by reducing travel time, improving predictability	Planned capability of ATM solutions to improve ATM performance	Validated capability of delivered solutions to improve ATM performance	Measured performance improvement

7.2.1. Evaluation framework

The evaluation of the Partnership will be done in full accordance with the provisions laid out in Horizon Europe Regulation Article 47 and Annex III, with external interim and ex-post evaluations feeding into the overall Horizon Europe evaluations. As set in the criteria for European Partnerships, the evaluations will include an assessment of the most effective policy intervention mode for any future action; and the positioning of any possible renewal of the Partnership in the overall European Partnerships landscape and its policy priorities. In the absence of renewal, appropriate measures will be developed to ensure phasing-out of Framework Programme funding according to conditions and timeline agreed with the legally committed partners ex-ante.

1. LEAD DG, DECIDE PLANNING REFERENCES

Co-Lead DG: Directorate-General for Mobility and Transport (MOVE); Directorate General Research and Innovation (RTD)

Decide number: PLAN/2019/5393

2. ORGANISATION AND TIMING

Institutionalised partnerships are foreseen in Articles 185 and 187 of the Treaty on the Functioning of the European Union (TFEU). The preliminary agreement on Horizon Europe contained a list of possible areas for institutionalised partnerships based on Article 185 and 187. For each of these areas the Commission considered 12 potential institutionalised partnerships. Their set up involves new EU legislation and the establishment of dedicated implementing structures and therefore an impact assessment for each of these initiatives.

Following political validation in June 2019, the impact assessment process started with the publication of inception impact assessments for each initiative in August 2019.

An inter-service steering group (ISSG) on research and innovation partnerships under Horizon Europe was set up in May 2019 and held 4 meetings before submission of the Staff Working Document to the Regulatory Scrutiny Board (7 May 2019, 19 June 2019, 5 December 2019, 20 January 2020). The ISSG consisted of representatives of the Secretariat-General, Directorate-General for Budget, Directorate-General for Research and Innovation Directorate-General for Communications Networks, Content and Technology, Directorate-General for Mobility and Transport, Directorate-General for Internal Market, Industry, Entrepreneurship and SMEs, Directorate-General for Energy, Directorate-General for Environment, Directorate-General for Climate Action, and the Legal Service.

An online public stakeholder consultation was launched between September and November 2019, gathering 1635 replies for all 12 initiatives.

3. CONSULTATION OF THE RSB

Two upstream meetings with the Regulatory Scrutiny Board of were held on 10 July 2019 and 30 September 2019.

In accordance with the feedback received from the Regulatory Scrutiny Board on 12.06.2020 the Staff Working Document has been revised as presented in Figure 1. The impact assessment was endorsed by the Inter Service Steering Group on 20.01.2020.

4. EVIDENCE, SOURCES AND QUALITY

To ensure a high level of coherence and comparability of analysis for all candidate initiatives, an external study was procured to feed into the impact assessments of the 12 candidate

institutionalised partnerships ¹ (Technopolis Group, 2020). It consisted of an horizontal analysis and individual thematic analyses for each of the initiatives under review.

For all initiatives, the evidence used includes desk research partly covering the main impacts and lessons learned from previous partnerships. A range of quantitative and qualitative data sources complement the evidence base, including evaluations; foresight studies; statistical analyses of Framework Programmes application and participation data and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options. Public consultations (open and targeted) supported the comparative assessment of the policy options. For each initiative up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition the analysis was informed by the results of the Open Public Consultation (Sep – Nov 2019), the consultation of the Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of candidate Institutionalised European Partnerships.

A more detailed description of the methodology and evidence base used, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

Figure 1 Modifications to the draft Staff Working Document based on comments received from the Regulatory Scrutiny Board

Comments from the Regulatory Scrutiny Board	Actions taken for the Staff Working Document
(1) The report does not sufficiently explain what the current joint undertaking has achieved. The report should better integrate evaluation findings on the current joint undertaking and explain how the new partnership would address them. The report should be clearer about the differences between the current joint undertaking and the future partnership.	Section 1.3, Box 3 was revised to provide additional information about the achievements of the current SESAR Joint Undertaking, as well as to provide information about how the new partnership will address them. Section 5.2, Tables 5 and 6 updated to include an outline of key differences between the current situation and different implementation methods.
(2) The report should clarify how the partnership will address air safety issues and to what extent this aspect will be considered in the development of innovative ATM solutions. The report should also elaborate on how far the partnership could enhance	Section 1 have been revised to clarify how safety has preserved its central role in the development of new technologies. The case for enhanced interoperability and reduced fragmentation was strengthened.

¹ Technopolis Group, 2020, forthcoming.

interoperability and reduce fragmentation.	
(3) The report should better describe the wider context in which the new partnership would operate. It should clarify the link with the European Air Traffic Management Master Plan and the Digital European Sky blueprint. It should be more realistic on the baseline developments of European aviation and on what the partnership can achieve.	Section 1 and 4 have been revised to elaborate the link between the Master Plan and the blueprint and to set them in the context of the Single European Sky policy objectives.
(4) The report should further elaborate on the partnership's expected role in bringing together relevant stakeholders and Member States around a common research and alignment agenda of European ATM systems.	Section 1 and 4 were updated to provide additional information about how all relevant stakeholders will be European ATM Master Plan and the Strategic Research and Innovation Agenda (SRIA) for integrated ATM and about the involvement of stakeholders in preparing these documents.
(5) The report could explain better the links between problems and objectives, and between objectives, targeted impacts and functionalities.	Section 4.3 was updated to better describe the impacts in relation to specific objectives and to describe the link between the intervention logic and the policy, as well as the planning tools, i.e. the European ATM Master Plan and the SRIA.
(6) The report should integrate the latest realistic expectations on the effects of the Covid-19 crisis on air traffic. It could consider these in the analysis of the problems, baseline and impacts.	Section 4, Economic and societal impacts were updated to reflect the current forecasts regarding the evolution of the aviation sector in the coming years. Overall, the impacts do not change significantly, as the initiative has a medium to long-term perspective. The Covid-19 crisis does not change the need for the European ATM system to become more resilient, scalable and sustainable.

Annex 2 Stakeholder Consultation

1. OVERVIEW FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1.1. Introduction

In line with the Better Regulation Guidelines,² the stakeholders were widely consulted as part of the impact assessment process of the 12 candidates for institutionalised partnerships, including national authorities, the EU research community, industry, EU institutions and bodies, and others. These inputs were collected through different channels:

- A feedback phase on the inception impact assessments of the candidate initiatives in August 2019, gathering 350 replies for all 12 initiatives on the “Have your say” web portal during a period of 3 weeks;
- A structured consultation of Member States performed by the EC services over 2019 through the Shadow Strategic Configuration of the Programme Committee of Horizon Europe (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.
- An online public stakeholder consultation administered by the EC, based on a structured questionnaire, open between September and November 2019, gathering 1635 replies for all 12 initiatives;
- A targeted consultation run by the external study contractors with a total of 608 interviews performed as part of the thematic studies by the different study teams between August 2019 and January 2020.

1.2. Horizontal results of the Open Public Consultation

The consultation was open to everyone via the EU Survey online system.³ The survey contained two main parts to collect views on general issues related to European partnerships (in Part 1) and specific responses related to one or more of the 12 candidate initiatives (as selected by a participant). The survey was open from 11 September till 12 November 2019. The consultation was available in English, German and French and advertised widely through the European Commission’s online channels as well as via various stakeholder organisations.

1.2.1. Profile of respondents

In total, 1635 respondents filled in the questionnaire of the open public consultation. Among them, 272 respondents (16.64%) were identified to have responded to the consultation as part of a campaign (coordinated responses). Based on the Better Regulation Guidelines, the groups of respondents where at least 10 respondents provided coordinated answers were labelled as ‘*campaigns*’, segregated and analysed separately and from other responses. In total 11

² https://ec.europa.eu/info/files/better-regulation-guidelines-stakeholder-consultation_en

³ <https://ec.europa.eu/eusurvey/runner/ConsultationPartnershipsHorizonEurope>

campaigns were identified, the largest of them includes 57 respondents⁴⁴. In addition, 162 respondents in the consultation also display similarities in responses but in groups smaller than 10 respondents. Hence, these respondents were not labelled as campaigns and therefore were not excluded from the general analysis.

Table 1: Country of origin of respondents (N=1635)

Country	Number of respondents	Percentage of respondents
Germany	254	15.54%
Italy	221	13.52%
France	175	10.70%
Spain	173	10.58%
Belgium	140	8.56%
The Netherlands	86	5.26%
Austria; United Kingdom	61	3.73%
Finland	49	3.00%
Sweden	48	2.94%
Poland	45	2.75%
Portugal	32	1.96%
Switzerland	28	1.71%
Czechia	24	1.47%
Greece	23	1.41%
Norway; Romania	22	1.35%
Denmark	20	1.22%
Turkey	19	1.16%
Hungary	14	0.86%
Ireland	12	0.73%
United States	11	0.67%
Estonia; Slovakia; Slovenia	10	0.61%
Bulgaria; Latvia	9	0.55%
Bosnia and Herzegovina	7	0.43%
Lithuania	4	0.24%
Canada; Croatia; Israel	3	0.18%
China; Ghana; Iceland; Japan; Luxembourg; Morocco	2	0.12%
Bhutan; Botswana; Cyprus; Iran; Malta; Mexico; Moldova; Mongolia; Palestine; Russia; Serbia; South Africa; Tunisia; Ukraine; Uruguay	1	0.06%

As shown in Figure 2, the three biggest **categories of respondents** are representatives of companies and business organisations (522 respondents or 31.9%), academic and research institutions (486 respondents or 29.7%) and EU citizens (283 respondents or 17.3%). Among the group of respondents that are part of campaigns, most respondents are provided by the same groups of stakeholders, namely company and business organisations (121 respondents or 44.5%), academic and research institutions (54 respondents or 19.8%) and EU citizens (42 respondents or 15.4%).

⁴⁴ The candidate Institutionalised Partnership Clean Hydrogen has the highest number of campaigns, namely 5. A few initiatives, such as Innovative SMEs, Smart Networks and Systems, were not targeted by campaigns. Some campaign respondents decided to provide opinions about several partnerships.

Figure 2 Type of respondents (N=1635) - For all candidate initiatives

Among all consultation respondents, 1303 (79.69%) have been **involved in the on-going research and innovation framework programme** Horizon 2020 or the preceding Framework Programme 7, while 332 respondents (20.31%) were not. In the group of campaign respondents, the share of those who were involved in these programmes is higher (245 respondents out of 272 or 90.07%) than in the group of non-campaign respondents (1058 out of 1363 or 77.62%). When respondents that participated in the Horizon 2020 or in the preceding Framework Programme 7 were asked to indicate in which capacity they were involved in these programmes, the majority stated they were a beneficiary (1033 respondents) or applicant (852 respondents). The main stakeholder categories, e.g. companies/business organisation, academic/research institutions, etc., show a similar distribution across the capacities in which they ‘have been involved in Horizon 2020 or in the Framework Programme 7’ as the overall population of consultation respondents.

Among those who have been involved in Horizon 2020 or the preceding Framework Programme 7, 1035 respondents (79.43%) are/were **involved in a partnership**. The share of respondents from campaigns that are/were involved in a partnership is higher than for non-campaign respondents, 89.80% versus 77.03% respectively. The list of partnerships under Horizon 2020 or its predecessor Framework Programme 7 together with the numbers, percentages of participants is presented in Table 4 **Error! Reference source not found.**, the table also show the key stakeholder categories for each partnership. Most consultation respondents participated in the following partnerships: Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, Clean Sky 2 Joint Undertaking, European Metrology Programme for Innovation and Research (EMPIR) and in Bio-Based Industries Joint Undertaking. The comparison between the non-campaign and campaign groups of respondents shows that the overall distribution is quite similar. However, there are some differences. For the campaign group almost a half of respondents is/was involved in the Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, a higher share of campaign respondents is/was participating in Clean Sky 2 Joint Undertaking and in Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking.

When respondents were asked in which **role(s) they participate(d) in a partnership(s)**, over 40% indicated that they act(ed) as partner/member/beneficiary in a partnership. The second largest group of respondents stated that they applied for funding under a partnership. The roles selected by non-campaign and campaign respondents are similar.

Table 4: Partnerships in which consultation respondents participated (N=1035)

Name of the partnership	Number and % of respondents from both groups (n=1035)	Number and % of respondents from a non-campaign group (n=815)	Academic/research institutions	Business associations	Company/business organisations	Company/business organisations	EU citizens	NGOs	Public authority
Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking	354 (33.33%)	247 (30.31%)	97	9	37	43	41	8	5
Clean Sky 2 Joint Undertaking	195 (18.84%)	145 (17.79%)	57	2	10	27	37	1	7
European Metrology Programme for Innovation and Research (EMPIR)	150 (14.49%)	124 (15.21%)	64	0	13	9	14	2	19
Bio-Based Industries Joint Undertaking	142 (13.72%)	122 (14.97%)	39	8	20	27	14	1	6
Shift2Rail Joint Undertaking	124 (11.98%)	101 (12.40%)	31	7	5	31	14	3	7
Electronic Components and Systems for European Leadership (ECSEL) Joint Undertaking	111 (10.72%)	88 (10.80%)	42	2	7	20	12	0	5
Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking	66 (6.38%)	46 (5.64%)	10	3	3	20	3	2	3
5G (5G PPP)	53 (5.12%)	47 (5.77%)	20	1	6	14	5	0	1
Eurostars-2 (supporting research-performing small and medium-sized enterprises)	44 (4.25%)	40 (4.91%)	17	0	6	1	7	0	6
Innovative Medicines Initiative 2 (IMI2) Joint Undertaking	37 (3.57%)	35 (4.29%)	18	2	3	3	2	4	3
Partnership for Research and Innovation in the Mediterranean Area (PRIMA)	28 (2.71%)	26 (3.19%)	15	0	3	1	2	0	2
European and Developing Countries Clinical Trials Partnership	25 (2.42%)	24 (2.94%)	12	0	1	2	3	3	2
Ambient Assisted Living (AAL 2)	22 (2.13%)	21 (2.58%)	11	2	1	1	3	0	3
European High-Performance Computing Joint Undertaking (EuroHPC)	22 (2.13%)	18 (2.21%)	6	0	2	3	5	0	2

For the remaining of the consultation respondents could provide their views on each/several of the candidate initiatives. The majority of respondents (31.4%) provided their views on the Clean Hydrogen candidate partnership. More than 45% of respondents from the campaigns selected this partnership. Around 15% provided their views for European Metrology, Clean Aviation and Circular Bio-based Europe. The share of respondents in the campaign group that chose to provide views on the Clean Aviation candidate partnership is of 20%. The smallest number of respondents provided opinions on the candidate initiative ‘EU-Africa research partnership on health security to tackle infectious diseases – Global Health’.

Table 5: Candidate Institutionalised Partnerships for which consultation respondents provide responses (N=1613)

Name of the candidate Institutionalised European partnership	Number and % of respondents from both groups (n=1613)	Number and % of respondents from a non-campaign group (n=1341)
Clean Hydrogen	506 (31.37%)	382 (28.49%)
European Metrology	265 (16.43%)	225 (16.78%)
Clean Aviation	246 (15.25%)	191 (14.24%)
Circular bio-based Europe	242 (15%)	215 (16.03%)
Transforming Europe’s rail system	184 (11.41%)	151 (11.26%)
Key Digital Technologies	182 (11.28%)	162 (12.08%)
Innovative SMEs	111 (6.88%)	110 (8.20%)
Innovative Health Initiative	110 (6.82%)	108 (8.05%)
Smart Networks and Services	109 (6.76%)	107 (7.98%)
Safe and Automated Road Transport	108 (6.70%)	102 (7.61%)
Integrated Air Traffic Management	93 (5.77%)	66 (4.92%)
EU-Africa research partnership on health security to tackle infectious diseases – Global Health	49 (3.04%)	47 (3.50%)

1.2.2. Characteristics of future candidate European Partnerships

Respondents were asked to assess what areas, objectives, aspects need to be in the **focus of the future European Partnerships** under Horizon Europe and to what extent. According to Figure 6, a great number of respondents consider that a significant contribution by the future European Partnerships is ‘fully needed’ to achieve climate-related goals, to the development and effective deployment of technology and to EU global competitiveness in specific sectors/domains. Overall, respondents’ views reflect that many aspects require attention of the Partnerships. The least attention should be paid to responding towards priorities of national, regional R&D strategies, including smart specialisation strategies, according to respondents.

Overall, only minor differences can be found between the main stakeholder categories. Academic/research institutions value the responsiveness towards EU policy objectives and focus on development and effective deployment of technology a little less than other respondents. Business associations, however, find that the future European Partnerships under Horizon Europe should focus a little bit more on the development and effective deployment of technology than other respondents. Furthermore, business associations, large companies as well as SMEs value the role of the future European Partnerships for significant contributions

to EU global competitiveness in specific sectors domains a little higher than other respondents. Finally, both NGOs and Public authorities put a little more emphasis on the role of the future European Partnerships for significant contributions to achieving the UN SDGs. The views of citizens (249, or 18.3%) do not reflect significant differences with other types of respondents. However, respondents that are/were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7 assign a higher importance of the future European Partnerships to be more responsive towards EU policy objectives and to make a significant contribution to achieving the UN’s Sustainable Development Goals.

A qualitative analysis of the “other” answers highlights the importance of collaboration and integration of relevant stakeholders to tackle main societal challenges and to contribute to policy goals against which fragmentation of funding and research efforts across Europe should be avoided. Additionally, several respondents suggested that faster development and testing of technologies, acceleration of industrial innovation projects, science transfer and market uptake are needed. Next to that, many respondents provided answers related to the hydrogen and the energy transition, which corresponds to the high number of respondents that provided answers to the candidate initiative on this topic.

Figure 6: To what extent do you think that the future European Partnerships under Horizon Europe need to (N=1363) (non-campaign replies) For all candidate initiatives

1.2.3. Main advantages and disadvantages of Institutionalised European Partnerships

An open question asked to outline the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe (1551 respondents). The advantages mentioned focus on the development of technology, overall

collaboration between industry and research institutions, and the long-term commitment. Disadvantages mentioned are mainly administrative burdens. An overview is provided below.

Advantages mentioned: Long term commitment, stability, and visibility in financial, legal, and strategic terms; Participation of wide range of relevant stakeholders in an ecosystem (large/small business, academics, researchers, experts, etc.); Complementarity with other (policy) initiatives at all levels EU, national, regional; Efficient and effective coordination and management; High leverage of (public) funds; Some innovative field require high levels of international coordination/standardisation (at EU/global level); Ability to scale up technology (in terms of TRL) through collaboration; Networking between members; Direct communication with EU and national authorities

Disadvantages mentioned: Slow processes; System complexity; Continuous openness to new players should be better supported as new participants often bring in new ideas/technologies that are important for innovation; Lower funding percentage compared to regular Horizon Europe projects; Cash contributions; Administrative burdens; Potential for IPR constraints.

1.2.4. Relevance of EU level to address problems in Partnerships' areas

Respondents were asked to rate the **relevance of research and innovation efforts at EU level efforts to address specific problems in the area of partnerships**. Research and innovation related problems were rated as most relevant across all candidate initiatives, followed by structural and resources problems and problems in the uptake of innovations. Overall, all three areas were deemed (very) relevant across the partnerships, as more than 80% of respondents found these challenges (very) relevant. Only minor differences were found between stakeholder categories. Research and innovation problems were found slightly more relevant by academic/research institutions, yet slight less relevant by large companies and SMEs. Structural and resource problems were indicated as slightly more relevant by NGOs, but slightly less by academic/research institutions. While both NGOs and public authorities find slightly more relevant to address problems in uptake of innovation than other respondents. The views of citizens are not differing significantly. Respondents that are/were directly involved in a current/preceding partnership find, however, the need to address problems related to the uptake of innovations slightly more relevant than other respondents.

Figure 9: To what extent do you think this is relevant for research and innovation efforts at EU level to address the following problems in relation to the candidate partnership in question? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.5. Horizon Europe mode of intervention to address problems

Respondents were asked to indicate how these challenges could be addressed through **Horizon Europe intervention**. Just over 50% of all respondents indicated that institutionalised partnerships were the best fitting intervention, with relatively strong differences between stakeholder categories. The use of Institutionalised Partnership was indicated more by business associations and large companies, but less by academic/research

institutions and SMEs. While academic/research institutions valued traditional calls more often, this was not the case for business associations, large companies and public authorities. Public authorities indicated a co-programmed intervention more often than other respondents. Citizens indicated slightly less often that institutionalised partnerships were the best fitting intervention. Respondents that are/were directly involved in a current/preceding partnership, selected the institutionalised partnership intervention in far higher numbers (nearly 70%).

Figure 10: In your view, how should the specific challenges described above be addressed through Horizon Europe intervention? (non-campaign replies) For all candidate initiatives

When asked to reflect on their answers, respondents that pointed to the need for using institutionalised partnership mentioned the long-term commitment of collaboration, a common and ambitious R&I strategy as well as the overall collaboration between industry and research institutions. Others shared positive experiences with other modes of interventions:

- Traditional calls, because of their flexibility and integration of a wide range of actors, as long as the evaluation panels do not deviate from the policy focus. This was mentioned by 94 participants, including companies (25), academics (26) and EU citizens (25).
- Co-funded partnership, as a mechanism to ensure that all participants take the effort seriously, while allowing business partnerships to develop. This approach was deemed suitable based on previous experiences with ERANETs. This was raised by 84 participants, 36 of them academic respondents, 18 companies and 16 EU citizens.
- Co-programmed partnerships, to tackle the need to promote and engage more intensively with the private sector. This was mentioned by 97 participants, most of them companies (34), followed by academics (22), business associations (15) and EU citizens (11).

1.2.6. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Setting joint long-term agendas

Respondents were asked how relevant it is for the proposed European Partnerships to meet their objectives to have a strong involvement of specific stakeholder groups in setting joint long-term agenda. All respondents see stakeholders from industry as the most relevant, followed by academia and governments. The involvement of foundations and NGOs as well as other societal stakeholders were, however, still found to be (very) relevant by more than 50% of the respondents. Most respondents indicated the stakeholder group they belong to themselves or that represent them as relevant to involve.

Figure 11: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Setting joint long-term agenda with strong involvement of: (non-campaign replies) For all candidate initiatives

Pooling and leveraging resources through coordination, alignment and integration with stakeholders

Respondents were asked how relevant it is for the proposed European Partnership to meet its objectives to pool and leverage resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with specific groups of stakeholders. Respondents see stakeholders from industry as the most relevant, followed by academia and governments (Member States and Associated Countries). The involvement of foundations and NGOs as well as other societal stakeholders are also still found to be (very) relevant for more than 50% of the respondents. Similarly as described for the question on setting joint long-term agendas, most stakeholder categories valued their own involvement higher than other respondents – although also here differences between stakeholder categories were minor.

Figure 12: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Pooling and leveraging resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with: (non-campaign replies) For all candidate initiatives

Composition of the partnerships

Regarding the composition of the partnership most respondents indicated that for the proposed European Partnership to meet its objectives the composition of partners needs to be flexible over time and that a broad range of partners, including across disciplines and sectors, should be involved (see Figure 13). When comparing stakeholder groups only minor

differences were found. Academic/research institutions and public authorities found the involvement of a broad range of partners and flexibility in the composition of partners over time slightly more relevant than other respondents, while large companies found both less relevant. SMEs mainly found the flexibility in the composition of partners over time less relevant than other respondents, while no significant differences were found regarding the involvement of a broad range of partners. Citizens provided a similar response to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, indicated a slightly lower relevance of the involvement of a broad range of partners and flexibility in the composition of partners over time.

Figure 13: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Partnership composition (non-campaign replies) Aggregation of responses of all candidate initiatives

Implementation of activities

Most respondents indicated that implementing activities like a joint R&I programme, collaborative R&I projects, deployment and piloting activities, providing input to regulatory aspects and the co-creation of solutions with end-users are all (very) relevant for the partnerships to be able to meet its objectives. Minor differences were found between the main stakeholder categories, the differences found were in line with their profile. As such, academic/research institutions found joint R&I programme & collaborative R&I projects slightly more relevant and deployment and piloting activities, input to regulatory aspects and co-creation with end-users slightly less relevant than other respondents. For SMEs an opposite pattern is shown. Large companies, however, also found collaborative R&I projects slightly more relevant than other respondents, as well as input to regulatory aspects. The views of citizens are similar to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, show a slightly higher relevance across all activities.

Figure 14: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Implementing the following activities (non-campaign replies) For all candidate initiatives

1.2.7. *Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements*

Respondents were asked to reflect on the relevance of setting up a legal structure (funding body) for achieving a set of improvements, as shown in the Figure below. In general, 70%-80% of respondents find a legal structure (very) relevant for these activities. It was found most relevant for implementing activities in a more effective way and least relevant for ensuring a better link to practitioners on the ground, however differences are small.

Figure 15: In your view, how relevant is to set up a specific legal structure (funding body) for the candidate European Partnership to achieve the following? (non-campaign replies) Aggregation of responses of all candidate initiatives

When comparing stakeholder categories there are only minor differences. Academic/research institutions indicated a slightly lower relevance for transparency, better links to regulators as well as obtaining the buy-in and long-term commitment of other partners. SMEs also

indicated a lower relevance regarding obtaining the buy-in and long-term commitment of other partners. Large companies showed a slightly higher relevance for implementing activities effectively, ensure better links to regulators, obtaining the buy-in and long-term commitment of other partners, synergies with other EU/MS programmes and collaboration with other EU partnerships. NGOs find it slightly more relevant to implement activities faster for sudden market or policy needs. Public authorities, however, find it slightly less relevant to facilitate collaboration with other European Partnerships than other respondents. The views of citizens show a slightly lower relevance for a legal structure in relation to implementing activities in an effective way. Respondents that are/were directly involved in a current/preceding partnership indicated a higher relevance across all elements presented.

1.2.8. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Consulted on the scope and coverage for the partnerships, based on their inception impact assessments, the large majority feels like the scope and coverage initially proposed in the inception impact assessments is correct. However, about 11% to 15% of the respondents indicated the scope and coverage to be too narrow. About 11%-17% of respondents answered “Don’t know”. Overall, differences between the main stakeholder categories were found to be minor. Academic/research institutions indicated slightly more often that the research area was “too narrow” than other respondents. SMEs on the other hand indicated slightly more often that the research area and the geographical coverage were “too broad”. NGOs and public authorities, however, found the geographical coverage slightly more often “too narrow”. Large companies found the range of activities slightly more often “too broad” and the sectoral focus slightly more often “too narrow” when compared to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership more often indicated that the candidate institutionalised European Partnership have the “right scope & coverage”.

Figure 16: What is your view on the scope and coverage proposed for this candidate institutionalised European Partnership, based on its inception impact assessment? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.9. Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

When asked whether it would be possible to rationalise a specific candidate European Institutionalised Partnership and its activities, and/or to better link with other comparable

initiatives, nearly two thirds of respondents answered “Yes” (1000, or 62%), while over one third answered “No” (609, or 39%). Nearly no differences were found between stakeholder categories, only large companies and SMEs indicated slightly more often “Yes” in comparison to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership, indicated “No” more often, the balance is about 50/50 between “Yes” and “No” for this group.

1.2.10. Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Finally, respondents were asked to rate the relevance of partnership specific impacts in three main areas: Societal; Economic/technological; and Scientific impacts. All three areas were deemed (very) relevant across the candidate partnerships. Scientific impact was indicated as the most relevant impact, more than 90% of respondents indicated that this as (very) relevant. Only minor difference between stakeholder groups were found. Academic/research institutions found scientific impacts slightly more relevant, while large companies found economic and technological impacts slightly more relevant than other respondents. NGOs found societal impact slightly more relevant, while SMEs found this slightly less important. Citizens did not a significantly different view when compared to other respondents. Respondents that are/were directly involved in a current/preceding partnership find all impacts slightly more relevant than other respondents.

Figure 17: In your view, how relevant is it for the candidate European Institutionalised Partnership to deliver on the following impacts? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.3. Stakeholder consultation results for this specific initiative

1.3.1. *Feedback to the inception impact assessment on candidate initiatives for Institutionalised Partnerships*

Following the publication of the inception impact assessment, a feedback phase of three weeks allowed any citizen to provide feedback on the proposed initiatives on the “Have your say” web portal. In total 350 feedbacks were collected for all initiatives.

For the initiative “Integrated Air Traffic Management” 28 individual feedbacks were collected, mainly from academic/research institutes, business associations, companies/business organisations and public authorities

Among the elements mentioned were:

- Institutional partnership under Article 187 of the TFEU is the one that best suits ATM.
- Baseline scenario of open calls is not an alternative to increase efficiency and speed up development or implementation of the Single European Sky of which EU economy and travelling public are the beneficiaries.
- A partnership for ATM is required due to the fragmented and conservative industry that without coordination will lead to stand alone research projects and lack of research continuity that will not help address the challenging tasks of R&I and deployment.
- ATM has specific challenges that require research coordination, expertise and resources from the whole value chain including key actors. Solutions that are still under development and future challenges are best address by a dedicated institutional ATM partnership
- The momentum, context and success of the SESAR Joint Undertaking should be followed up. The participation stability, resilience and experience acquired in the last 10 years by SESAR’s systematic approach are required in order to follow the learning curve that will allow to address the future challenges.
- ATM due to its nature requires to ensure participation from cross-industry stakeholders, effective coordination and efficient execution across the network in order to bring economies of scale amongst a unified vision such as the current European ATM Master Plan, Flightpath 2050 goals or Single European Sky framework. In order to ensure this, political consensus in required.
- A free market will not lead to investments due to them being prohibitively high at an early stage. A European partnership is needed to ensure that R&I investments add value for the public and support job opportunities, sustainable, safety and innovative initiatives. This will allow to have a functioning international air traffic management that is beneficial for a transport network and a guarantor for the economic development in Europe.
- The partnership should create a systematic approach to successfully address the challenges of digitalisation (including augmented and virtual reality), Artificial Intelligence, big data, block chain, cyber security, automation, optimisation, sustainability, maximum environmental efficiency, accommodation of new airspace users, accommodation of traffic in complex airspace and single-pilot operations.
- Take a holistic approach that includes an adapted regulatory framework, operational aspects and development and maturation of the critical enabling technologies. Standardisation, and implementation are crucial to develop an interoperable, scalable and harmonised EU ATM system that safe, efficient, sustainable, connected, airspace and air transport.

- ATM Modernisation is a global issue and the partnership should keep a global mindset pushing towards harmonisation without leaving behind the R&I European focus. It should encourage networking and cooperation to promote EU standards at a global level in order to implement solutions that can be leveraged in terms of global industry. Solutions should be in line with ICAO recommendations and EASA regulations, especially for drones.
- To ensure better transition through the R&I pipeline and acceleration of development processes. Exploratory research is essential to feed the innovation pipeline and must be reinforced whilst accepting uncertainty to allow innovation. Reduction in bureaucracy, administrative overhead, funding flexibility and making results fully available could allow a smoother transition from R&I to development.
- Better regulation is key to close the gap between validation and industrialisation. It will enable to have a synchronized, coordinated and harmonized deployment of technologies based on positive Cost Benefit Analysis. Launch pilot and demonstration projects will also promote this.
- All types (and size) of stakeholders should contribute to the partnership, ensuring leader roles and responsibilities as well as a robust institutional governance. It is crucial to include the industrial or suppliers, social partners representing “human in the loop”, service providers or operational stakeholders such as airspace users (this should be reinforced) and regulators like EASA. To enable this it should facilitate openness to enable newcomers to join and covering the whole European network including non-EU associate members that play a significant role.
- Diverging interests from the industry and service providers should not influence the research and development priorities but it should be kept customer and result driven. The focus should be on operational performance benefits for the whole network and society (including passengers).
- An ATM partnership should learn from other industries and domains whilst keeping a strong communication with affected communities. An example is to cooperate closely with Clean Sky. It should also apply lessons learned from previous ATM partnerships such as the SESAR Joint Undertaking.
- Coordination and clarity in the policy, vision, strategy/planning objectives and roles is necessary. The partnership should be in line with the European ATM Master Plan and ensure its maintenance, including recommendations of Airspace Architecture Study, Wise Person Group and European Court of Auditors report on the Single European Sky.

1.3.2. Structured consultation of the Member States on European partnerships

A structured consultation of Member States through the Shadow Strategic Configuration of the Programme Committee Horizon Europe in May/June 2019 provided early input into the preparatory work for the candidate initiatives.

For the initiative “Integrated Air Traffic Management” the following overall feedback was received from Member States. There is good agreement with the overall objectives, with some delegations proposing additional elements to strengthen the proposal – notably the research and innovation aspects. For smaller / EU-13 countries, better integration of aspects related to digitalisation, drones and small aircrafts into the EU ATM system would significantly increase the relevance of the partnership. Several countries highlight the need to elaborate on the involvement of Member States, the national services responsible for regulating and controlling air traffic. Comments also suggest broadening the partner composition with new categories of stakeholders.

Relevance and positioning in a national context

Overall the feedback from countries confirm the relevance of the proposed European Partnership for Integrated Air Traffic Management, with 74% considering it very or somewhat relevant for their national policies and priorities, and for their industry, and slightly less (63%) considering it relevant for their research organisations, including universities.

Figure 1: Relevance of the European Partnership for Integrated Air Traffic Management in the national context

On the question of existing national/regional R&I strategies, plans and/ or programmes in support of the proposed Partnership, 17 countries report to have relevant elements in place. National R&I strategies or plans (52 %, AT, DE, ES, FR, HR, IE, IT, LV, NL, RO, SE, SI, NO) and national economic, sectoral strategy and/or plan with a strong emphasis on research and/or innovation (52 %, AT, ES, FI, FR, HR, HU, IE, IT, LV, NL, RO, SE, SI, NO) were identified most frequently. Countries reported to a lesser extent to having regional R&I and/or smart specialisation strategies (37 %, DE, ES, FR, HR, IE, IT, SE, SI, UK, NO), dedicated R&I funding programmes or instruments (30 %, DE, ES, FR, HR, IE, IT, RO, ES). 22% of countries (CZ, ES, HR, IE, SE, NO) reported other policies/ programmes, such as upcoming sectoral agenda, a national research innovation agenda, or R&I programmes focusing more broadly on disruptive technologies.

Delegations identified a number of aspects that could be reinforced in the proposal for this partnership that would increase its relevance for national priorities.⁵ Some delegations emphasised the need to more use of the results of the Airspace Architecture Study⁶ and the report of the Wise Persons Group on the Future of the Single European Sky⁷ that indicate a number of concrete recommendations aimed at optimising Europe's airspace organisation in such a way that can facilitate the uptake of new technologies, including research on the benefits, risks and effects of these proposals. Other individual comments make suggestions to further strengthen the following areas: reduction of departure/arrival delays, taxing and more

⁵ Comments on scope and content have to be assessed in the context of the overall priority setting to ensure coherence.

⁶ A proposal for the future architecture of the European airspace, SJU, 2019.

⁷ Report of Wise Persons Group on the future of the Single European Sky, 2019.

efficient local traffic management, Human Performance, Safety Performance and Cybersecurity, short term challenges like airspace capacity, integrating drones, and ATM efficiency and aviation safety. In the additional comments some countries reiterated the relevance of the Partnership and overall agreement with the proposed objectives, whilst others express the need for a more integrated/ systemic approach (including by merging the proposed partnership with the one on Clean Aviation), a stronger focus on research activities and better involvement of Member States in the agenda setting.

Most countries (63%) are at this stage undecided concerning their interest to participate, as a partner. At this stage 8 country (CZ, DE, ES, FR, CR, IE, IT, MT) express interest to join as a partner, and 4 (CY, EE, HU, IS) countries express no interest to participate.

A small share of countries report as potential partners or contributors regional R&I and /or smart specialisation strategies (33%), governmental research organisations (33%), research infrastructures (30%), and existing or planned national R&I programmes (30% and 26% respectively). Additional comments highlight countries wish to further clarify national involvement and contributions in the proposed partnerships. While some respondents express readiness for aligning national funding initiatives and contributing to the Partnership, others prefer to limit national involvement to aligning policies and exploiting synergies (notably with Cohesion Funds), but without any further commitment of funding.

While most are undecided concerning their participation, almost all countries (93%) expressed interest in having access to results produced in the context of the partnership.

Feedback on objectives and impacts

Overall there is a good agreement (74%) on the use of a partnership approach in addressing challenges related to air traffic management. There is strong agreement (70%) that the partnership is more effective in achieving the objectives and delivering clear impacts for the EU and its citizens, but to lesser degree that (56%) it would contribute to improving the coherence and synergies within the EU R&I landscape.

Member States indicate strong agreement with the proposed objectives at short, medium and long term (82%) and the expected scientific, economic and societal impacts at European level (82%), with the remaining ones remaining neutral. 71% of countries consider the impacts very or somewhat relevant in the national context. 70% of countries found the envisaged duration of the proposed partnership adequate, while 19% of countries need more information to assess this. Individual additional comments in relation to objectives highlight the following:

The need to address more research and innovation agendas;

The need to encourage deployment and implementation of new solutions;

Support stronger links with other related partnership candidates, notably to promote connectivity across transport modes;

More focus on accelerating digitalisation, integrating drones and small aircrafts into the EU ATM system, and security aspects (in addition to safety).

Views on partners, contributions and implementation

Majority of countries (62%) agree with the proposed type and composition of partners, and 26 % of respondents need more information for informed decision. In additional comments, several countries emphasised the need to move away from the current set up of the SESAR JU towards a model that facilitates the participation of smaller players and SMEs (e.g. in relation to the use of drones). Several countries highlight the need to elaborate on the involvement of Member States, in particular the national services responsible for regulating and controlling

air traffic. Comments also suggest to broaden the partner composition with new categories of stakeholders, such as communication and data service providers or regions with smaller airports represented by private partners and research organizations. Individual feedback also suggests increasing the level of cooperation with the military air traffic and European Union Aviation Safety Agency (EASA) to speed up the process of technology, and to engage citizens and civil society (as changes to the ATM will have impacts on when people will travel).

At this stage, most countries (74%) would need more information on contributions and level of commitments expected from partners.

The proposed use of Article 187 implementation mode is supported by 41% of countries, while 48% would require additional information. Whilst several countries express the added value of having an institutionalised partnerships, many also stress the need to ensure high level of openness and transparency of the JU model (notably by ensuring open competitive calls, and removing entry barriers for the participation of smaller organisation). At the same time, there are also some delegations expressing support to implementing this priority with a co-programmed partnership, and some who suggest a merger with the Partnership on Clean Aviation.

1.4. Targeted consultation of stakeholders

Targeted consultations with businesses, research organisations and other partners on different aspects of the potential on integrated Air Traffic Management.

Details about the methodology and specific interview are presented in the annexes of the Technopolis study.

Table 1: Number of interviews per stakeholder category

Stakeholder category	Number	Share (%)
Academia	2	4%
Airports	3	6%
Airspace user community	5	10%
Air navigation service providers (ANSPs)	7	14%
ATM institutions	7	14%
Member States/ Single European Sky (SES) Committee	3	6%
R&D organisations	2	4%
SESAR Joint Undertaking executive	8	16%
SMEs	2	4%
Staff	1	2%
Suppliers	6	12%
The UAV community	4	8%
TOTAL	50	

Key results/messages from the targeted consultation

It is worth noting that despite the variety of stakeholders' types, the responses to the stakeholder consultation show there is a strong consensus on their views of ATM R&I, with only slight differences, mainly in the details.

Emerging challenges

The need to modernise the existing system through the application of emerging technologies such as digitalisation, automation and big data was a recurrent theme amongst the interviewed and throughout all the categories. Generally, and more specifically airspace users, see as the main challenge addressing environmental sustainability. In addition, various stakeholders from the airspace user community, ANSPs, ATM institutions and Member States categories, brought up the fact that these challenges are very well reflected in the Airspace Architecture Study.⁸

In addition, airspace user community believe there should be further research in relation to manned and unmanned vehicle interaction.

⁸ SESAR Joint Undertaking (2019). A proposal for the future architecture of the European airspace. Available at <https://www.sesarju.eu/node/3253>.

EU positioning

Many stakeholders in the categories of ANSPs, ATM institutions and SESAR Joint Undertaking agree that European R&I ATM has currently a strong position worldwide, due to having built over the years a coordinated programme that has allowed them to have discussions at ICAO level and be an example for other parts of the world. Furthermore, some stakeholders, specially ATM institutions and the UAV community, stated the EU is losing its upfront position in some of the emerging markets since they develop quicker than the ATM solutions. In this area, the lack of coordinated R&I included in the ATM programme, would leave Europe behind other regions as China and USA which are investing heavily in the drones and UTM research and development.

Previous programmes

A typical comment, especially in the categories of ANSPs, Member States, staff and the SESAR Joint Undertaking executive, regarding the current R&I ATM partnership, SESAR Joint Undertaking (SJU), is that the past ten years allowed the programme to reach a mature situation creating a momentum in the industry, and the advantages of the partnership that has a common vision and will to implement it, can now be exhaustively exploited. SJU experience and results are the fruit of a continuous learning curve, which should be built upon, and lessons learned should be used for future improvements. Stakeholders across all the categories, stated that the SJU has achieved a balanced partnership, except for the need to involve EASA, standardisation bodies, and some new key players such as the UAV community.

There were comments from stakeholders that have been long time in the industry such as in ANSPs, ATM Institutions, suppliers and Member States that agree framework programmes previous to the SJU had a fragmented nature and were a proof that, in ATM, European network benefit is only achieved if there is coordination, and direction accomplished through the consensus across the whole industry. Furthermore, they agree we should not go back into those days given the challenges in front of the industry and national authorities.

Potential synergies between partnerships

A closer interaction with Clean Sky is required in order to avoid duplication, a greater coordination and synergies on the topics of automation and environment in aviation. However, almost every stakeholder interviewed in every category sees no benefit in merging. Merging the partnerships would not make sense due to their different *objectives, scope, timeline to deployment and KPIs*. In case of merger, we would have two subprogrammes under one partnership with funds distribution disputes and an increase in managerial complexity. This was further emphasised by the stakeholders that are involved in both partnerships.

With Shift to Rail the scope and the technologies to be researched are just too different. It would be a good idea to interact on the multimodality matters.

Directionality

Stakeholders across all the categories consider there is a need for EU funding on ATM research. They believe it provides directionality and coherence to an industry that cannot be developed nationally due to the cross-border nature of aviation operations which requires interoperability of national ATM systems. EU funding acts as a mechanism or framework to develop a common view on the future path and avoid singularities of nations or private companies.

Coordination

Action from EU, as stated by most stakeholders across all the categories, provides steering, avoids fragmentation and harmonises the whole value chain of ATM stakeholders. It ensures the benefits are accrued at European network level, thus providing latest technology to all stakeholders, in all geographical areas, not only for the most developed countries.

EU funding of R&I is required to attract investment and commitment from the industry. This is due to the need to outweigh the heavy administration, use of resources, and effort needed to participate in the EU funded R&I. Suppliers, R&D organisations and SMEs emphasised that they believe it is best to invest and commit to a future common path that benefits the whole European network. They need to see an eventual benefit that is worth the investment in order to overcome their individual interests of developing their own R&I and products in isolation, in the favour of a common architecture and goal. Industrial stakeholders such as suppliers and ANSPs stated this would happen if there was no EU funding.

European ATM Master Plan and Airspace Architecture Study as ATM R&I guidelines

Mentioned as a need by stakeholders in all the categories is the fact that a significant amount of future R&I is needed to complete the current research agenda and deliver the solutions under the latest edition of European ATM Master Plan.⁹

One of the objectives the potential partnership should have, to which all the stakeholders agree is the maintenance and update the European ATM Master Plan. The European ATM Master Plan sufficiently describes R&I needs in the long term, however the Airspace Architecture Study is a more detailed plan that prioritises the research needs in the shorter term. These need to be better linked with other strategic planning documents like EASA's European Plan for Aviation Safety,¹⁰ Deployment Programme,¹¹ Network Strategic Plan.¹² The European ATM Master Plan should also be more performance driven than it is today.

However, some stakeholders in various categories were critical regarding the heaviness of the document which requires changes so that is more understandable to members of public. There is some criticism of the Master Plan's lack of a far-seeing and innovative vision which the AAS does take into account. Thus, as said by stakeholders from airports, airspace user community, ANSPs, ATM institution, SESAR Joint Undertaking executive and suppliers, the Master Plan should include the AAS findings.

Furthermore, the European ATM Master Plan updates need to involve in consultation all the stakeholders as it is done currently.

R&I fragmentation

Many stakeholders across all categories directly or indirectly referred that the main problems of ATM are fragmentation of R&I and, consequently, operations. In the event of having no partnership, or a partnership without a neutral and strong coordinating body, fragmentation would be caused by two main reasons: diverging industry interests and sovereignty. This would worsen the current lack of interoperability. Most stakeholders, especially in the industrial and institutional side of the value chain: airspace user community, ANSPs, ATM institutions, Member States, SESAR Joint Undertaking executives, staff, suppliers and the

⁹ SESAR Joint Undertaking (2019). European ATM Master Plan: Digitalising Europe's Aviation Infrastructure, Executive View, 2020 edition

¹⁰ EASA (2019). European Plan for Aviation Safety 2019-2023

¹¹ SESAR Deployment Manager (2018). Deployment Programme edition 2018

¹² EUROCONTROL (2015). Network Strategic Plan 2015-2019

UAV community, agree the interoperability is a key for a cross boundary industry such as aviation. Furthermore, they believe lack of interoperability is one of the key topics that needs further research in ATM since it leads to many issues. Thus, lack of coordination and direction in the ATM R&I would lead to R&I fragmentation, which has been highlighted as a problem that is a source of many other problems.

ATM system modernisation

Some stakeholders in the categories of service providers and suppliers mentioned that one of the needs is to develop a network centric system that is scalable, resilient and flexible to quickly adapt to external changes or new technologies. A system with these characteristics would solve the problem of airspace capacity which is strongly linked with other ATM inefficiencies.

As commented in the section on emerging challenges, stakeholders in all the categories make the point that R&I should focus on developing new technologies and concepts (e.g. automation or artificial intelligence) that aim at the overall system modernisation and digitalisation (ANSPs, suppliers and the UAV community emphasised the importance of digitalisation and automation).

R&I pace and its link with deployment

The pace of R&I is about right today. Acceleration, if needed, should not constrain quality nor safety. However, deployment does need to be accelerated through paying more attention to the implementation challenges (e.g. very large demonstrations and early demonstrators) and change management needed for deployment. This will allow to implement breakthrough technologies faster. Fundamental (exploratory), industrial and validation research activities are all needed, giving more importance to the validation exercises since it collects evidence for standards and regulations which facilitate deployment. There is a need to get closer to deployment and close gaps between the research and industrialisation phases. Eight of twelve stakeholder groups noted that closer cooperation and involvement of EASA and EUROCAE would support narrowing of the gap between the R&I and industrialisation phases. This issue was not commented on by academia, airports, R&D organisations and SMEs. Some stakeholders believe R&I should get a bit closer but to keep it separate from deployment while others believe it would be good to get very close or even into deployment using CEF funds. Airspace users agree that the end users such as ANSPs, airspace users and airports should be the ones driving R&I since they are more aware of the needs and it would avoid emergence of diverging interests among suppliers.

In addition, some stakeholders mentioned the need of prioritising R&I as it moves towards higher TRLs on its way to deployment.

Openness and transparency

Openness and transparency are important to be considered but there is a wide view that the current partnership, SESAR Joint Undertaking, addresses these values correctly. Fragmented data sharing needs to be tackled in order to enable the use of big data techniques. Communication of the research and solutions developed has to be kept as it is in the current partnership with expectations to keep improving it.

Comparative assessment of the policy options

Baseline

Throughout all the categories, stakeholders made the strong point that there is a need to build a partnership as a body that can steer the R&I coordinating key stakeholders continuously, to

achieve the common EU-wide long-term ATM vision. Thus, the baseline is not considered by them as a feasible option.

Co-programmed

A couple of stakeholders inside the categories of airports and the UAV community suggested that a co-programmed partnership could be a good idea in order to promote more competition between ideas and bring innovation whilst giving more opportunities and enhance the competitiveness of SMEs. However, a stakeholder from the SME category mentioned co-programmed could pick either the best or worst direction, and would likely be controlled by the big players. It was also seen as the preferred option by a stakeholder from the airspace user community since they believe it limits national influence. However, most of the stakeholders see it as a partnership type that lacks the cohesive strength required to move the R&I in the direction that has EU-wide benefits as a goal. Even if the European Commission may act as coordinating figure, it is not likely that the general Horizon Europe services would necessarily have core industry expertise to be able to coordinate R&I taking into account the long-term goals of deployment of results (as the services focus on R&I, not the uptake). The fact that it is non-legally binding creates a big risk in commitment from the key stakeholders leading to diverging interests.

Furthermore, many stakeholders, especially those at institutional level, agree that a co-programmed partnership would not have a necessary neutrality of coordination (given diverging interests). As co-programmed partnership would not have a status of a state institution, it would lose the ability to represent the EU ATM interests on international stage.

Institutional partnership under article 187

To progress the R&I in ATM and produce benefits for the entire society and network, there is a need to have legally binding commitments, strong leadership and steering because high efforts are required. In addition, the nature of ATM requires to have private members which have the industry experts but also public authorities such as EUROCONTROL and the European Commission in the centre to be the guiding light. Therefore, most of the stakeholders share the conviction that an institutionalised partnership (IP) under Article 187 with a similar set up to SESAR Joint Undertaking is the best option.

Furthermore, the current partnership achieved a unique vision for the future and the consensus between the stakeholders on the roadmap. The IP under Art 187 would push further the previous effort and make sure the last 10 years were not in vain.

Discarded options: co-founded and institutional partnership under article 185

Every interviewed stakeholder in all the categories, including stakeholders in the Member States category, made clear the point that in the ATM industry the relevant stakeholders are both in the public and in the private sector. The knowledgeable expertise can mainly be found in the private sector and the public sector is mainly composed by the Member States which do not get involved in R&I as such. This was highlighted when the Member States forwarded our interview invitation to their Single Sky Committee representatives (or advised to talk to their ANSP representative) as their role is in steering the R&I at a higher level, through providing opinion and approving the European ATM Master Plan.

Therefore, due to the low participation of public authorities in the R&I and the need to include the private industry, all the stakeholders (including those from Member States/SES) agreed that co-founded and institutional partnership under article 185 should be discarded.

The preferred option

Stakeholder involvement

One of the key added value of the current partnership is that it brings together the key stakeholders of the value chain to agree on the key European issues whilst keeping it manageable. This should be kept in the preferred option. However, some stakeholders across all the categories commented on the possibility of extending the partnership to the UAV community, business aviation, regulators, communication service providers and satellite communication service providers, and to have a stronger involvement of EASA (as a regulator) and standardisation bodies (e.g. EUROCAE). Airspace users, SMEs, staff and supplier stakeholder groups did not directly cite the inclusion of drones, but did endorse the European ATM Master Plan as a good strategic agenda (which includes these emerging challenges). There is a need to further involve airspace users and make R&I more market-driven for which EASA needs to be strongly involved. It would be interesting, if they exist, to involve experts in change management. Some stakeholders made the point of bringing innovative companies with cutting-edge solutions in the partnership, with the caveat to ensure they are stable.

Most of the airspace users stated that they do not have resources to participate directly in the research activities, but would like stronger involvement in the partnership similar to the current one. In the current one, they have a voice in the governance, but would like to expand that to the opportunity for higher involvement in the work.

Increase flexibility

There should be flexibility to enrol different stakeholders. Airspace users, the drone community, academia, SMEs and innovative companies should be enrolled in the partnership specially in topics where they can add significant value, but taking care to keep the governance manageable. In order to do so, some interviewees, especially in the ANSP and supplier category, suggested these could be involved as third party beneficiaries, through open calls or having different membership options with different membership fee and resource contribution. In having different membership options, it was mentioned that even if the contribution is different having members with different levels of say around the table adds complexity, so they should have the same say but not the same project engaging options.

Level of funding

The funding level of SESAR 2020 is the minimum needed. It must be borne in mind that if adding into the scope of the partnership, either by including new wide topics such as drones and digitalisation or by implementing Very Large Demonstration/ early adopters to get solutions closer to deployment, the funding should double. There is a threshold in the funding under which there is no leverage of the investment.

Winding down

Some suggestions from stakeholders, interviewed in the categories of ATM institutions and SESAR Joint Undertaking executive, on when to close down the institutional partnership include: once the European ATM Master Plan is achieved and the system only needs to be maintained in order make sure it does not degrade, once the process of digitalisation is sufficiently mature or once the industry is able to coordinate themselves following a strategic research and innovation agenda and overcoming individual interests.

This would slowly take place by reducing activity and switching from a strong coordinating body to a monitoring body.

1.5. Open Public Consultation

1.5.1. Characteristics of respondents

There are 66 respondents who have answered (part of) the consultation for the Integrated Air Traffic Management Partnership. Of these respondents, 10 (15.15%) were citizens. The largest group of respondents were businesses with 28 (42.42%) respondents. There were 8 respondents from academic and research institutions (12.12%) and 7 from both public authorities and business associations (10.61%). The remaining respondents were from NGO's (2, 3.03%), environmental organisations (1, 1.52%) and other (3, 4.55%). both with 123 respondents (32.20%). Over 3/4s of respondents, namely 51 (77.27%), have been involved in the on-going research and innovation framework programme, of which 38 respondents (74.51%) were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7.

1.5.2. Results on general questions

Relevance of efforts of the candidate European Partnership to address problems

At the beginning of the consultation, the respondents were asked on their views of the needs of the future European Partnerships under Horizon Europe. All 66 respondents answered this question. Overall, respondents indicated that many of these needs were very relevant. The needs where most respondents indicated this, was focusing more on the development and effective deployment of technology (39, 59.09%) and making a significant contribution to EU efforts to achieve climate related goals (37, 56.06%). Aside from 'other', the options where the least amount of respondents indicated that they were very relevant, being more responsive towards priorities in national and/or regional R&I strategies (16, 24.24%). In the case of this option, the responses differ. This is also the only option (aside from other), where multiple respondents have indicated that it is not needed at all.

No statistical differences were found between the views of citizens and other respondents.

Figure 1: Views of the respondents in regard to the needs of future European Partnerships under Horizon Europe (N=66)

The respondents also had the option to indicate other needs. The results show that respondents have indicated needs around extensive support linkage, sustainable stakeholder development and safety.

The respondents also had the option to indicate other needs. Some indicated that ensuring the safety levels are taken into account is important. A few called for implementation of strategic research agenda and the long-term vision. Another topic was the importance of bridging the gap between the research and actual deployment of researched innovation. To finish with the call for paying attention to regulation from early research stages.

Main advantages and disadvantages of participation in the Institutionalised European Partnership

The respondents were asked what they perceived to be the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe. The keyword analysis used for open questions resulted in the graph shown in Figure 20. This analysis showed the respondents mentioned administrative burden, research and innovation programme framework and political agendas.

1.5.3. Results on the Integrated Air Traffic Management initiative

Relevance of research and innovation efforts at the EU level to address problems

In the consultation, respondents were asked to provide their view on the relevancy of research and innovation efforts at EU level to address the following problems in relation to air traffic management, specifically on three types of problems: problems in uptake of air traffic management innovations (UI-P), structural and resource problems (SR-P) and research and innovations problems (RI-P). In Figure 21, the responses to these answers are presented.

Figure 2: Views of respondents on relevance of research and innovation efforts at the EU level to address problems in relation to air traffic management

With regard to the uptake in innovation problems, 29 respondents have indicated that the research and innovation efforts at the EU level to address the issue of slow pace of Air Traffic Management modernisation is very relevant (48.33%), and further 25 stated it is relevant – 90% of all respondents, across all categories, find this as a relevant problem. Regarding other uptake of innovation problems, like absence of clear vision for future systems, regulation impeding the uptake of innovation and investments featuring negative cost-benefit analysis, about 60% of respondents stated that these are either very relevant or relevant. Furthermore, majority of individual stakeholders consider the absence of standards as one of the problems in uptake of air traffic management innovations (30% stated very relevant and 37% relevant problem). Majority of academic and half of business association stakeholders do not consider this problem as relevant.

There are large differences in the responses that the respondents have given with regard to structural and resource problems. 52 respondents have indicated that the need to bring together the Air Traffic Management research community is very relevant (82.54%). This problem has the most ‘very relevant’ answers of any of the problems that the respondents were asked to reflect on. About 85% of respondents stated that the questions of appropriate budget and the need to coordinate public funding with private research and innovation funding received are either very relevant or relevant. Another important finding is that 52 respondents (82%) stated that the need to synchronise research and innovation activities with EU policy objectives is very relevant or relevant in the ATM. While another of the structural

problems outlined: skills required for researchers in this area, only received 17 very relevant answers (27.42%). No specific differences in responses have been noted across different stakeholder categories.

Two of the research and innovation problems have received over 30 responses indicating that they are very relevant problems, namely the fragmentation of EU airspace and the misalignment between R&I and the needs of operational stakeholders. Almost 80% of stakeholders declared that fragmentation of EU airspace is relevant (13, or 21%) or very relevant (24, or 58%) problem to be addressed by research and innovation efforts at EU level. The two other problems only received a little over 10 of very relevant responses (12, 19.35% and 13, 20.97% respectively).

Slight statistical differences were found between the views of citizens and other respondents. Citizens found the “research and innovation problems related to more relevant and the structural and resource problems” less relevant. Respondents involved in a current or preceding partnership (Horizon 2020 or Framework Programme 7), found the uptake in innovation problems regarding regulation and the absence of a clear vision for future system less relevant.

Horizon Europe interventions to address problems

After providing their views on the relevance of problems, respondents were asked to indicate how these challenges could be addressed through Horizon Europe intervention. As shown in Figure 22, over 60% of respondents indicated that institutionalised partnerships were the best fitting intervention.

Citizens, compared to other respondents, indicated less often that institutionalised partnerships were the best fitting intervention.

Figure 3: Assessment of Horizon Europe intervention

The respondents were asked to briefly explain their answers to the question above. People who stated that an institutionalised partnerships was the best fitting answer, mentioned that the current partnership mechanism worked well, and that in order to achieve common EU-level goals, this should be continued. The changes to the current settings mentioned by respondents relate to the need of more flexibility to be able to address changing goals in an agile manner. Further reasons included the statements that the entire ATM value chain is needed, where the respondents feel that the involvement of the value chain around the common strategic agenda in ATM is possible only through the Institutionalised Partnership. Further, the military cooperation on ATM issues should be formalised in the case of partnership continuation. Most of the respondents choosing this option mention the need to reduce as much as possible the administrative burden. Respondents choosing the Co-programmed partnership (N=11) mentioned this being the middle ground between the offered options when complexity of the agenda, flexibility of partnership and costs are taken into account. The respondents choosing the Traditional calls mentioned that those are very well established (i.e. evaluation, management), and more open to competition, reducing the number of funding instruments. Most of the respondents choosing the Traditional calls are from citizen category.

Relevance of involvement of actors in setting joint long-term agenda

Respondents were asked how relevant the involvement of actors is in setting a joint long-term agenda to ensure that the proposed European Partnership would meet its objectives (Figure 24). The highest amount of respondents indicated that the involvement of Industry is very relevant (46 respondents or 69.70%). A large part of respondents also indicated that the involvement of Member States and Associated Countries (38, 57.58%) is very relevant. Less respondents indicated that the involvement of academia, foundations and NGO’s and other stakeholders was very relevant. However over half of the respondents have indicated given academia and foundations either a score of 4 or 5 (very relevant) on the relevance scale. For other stakeholders this percentage is 37.87%.

No statistical differences were found between the views of citizens and other respondents.

Figure 4: Views of respondents on relevance of actors in setting a joint long-term

Relevance of elements and activities in pooling and leveraging resources

With respect to the relevance of actors in pooling and leveraging resources, such as financial, infrastructure, in-kind expertise etc.), to meet Partnership objectives, the patterns are very similar. Most of the respondents (47, 75.81%) indicated that industry was very relevant. A large part of respondents also indicated that the involvement of Member States and Associated Countries (33, 55.93%) and Academia (22, 35.48%) is very relevant. Also, similar to the previous question, the Foundations and NGO’s and other stakeholders were seen as less relevant and the opinions of the respondents seem divided on these types of stakeholders. No respondents indicated that any of the categories was Not relevant at all.

No statistical differences were found between the views of citizens and other respondents.

Figure 5: Views of respondents on relevance of actors for pooling and leveraging resources

Relevance of the partnership composition

Respondents were asked about the relevance of Partnership composition, such as flexibility in the composition of partners over time and involvement of a broad range of partners (including across disciplines and sectors), to reach Partnership objectives. As it is visible in Figure 26, these questions were answered similarly. Ensuring involvement of a broad range of partners has slightly more ‘very relevant’ answers (26, 41.94%) than the flexibility in the composition of partners (23, 41.07%). Overall 75% of respondents have given flexibility either a score of 4 or 5 (very relevant) which is higher than the 70.97% who have given the broad range of partners a score of 4 or 5 (very relevant).

No statistical differences were found between the views of citizens and other respondents.

Figure 6: Views of respondents on relevance of partnership composition elements

Relevance of implementation of activities

Respondents were asked to provide opinions on relevance of implementation of several activities for meeting objectives of the Integrated Air Traffic Management Partnership. Among activities were listed – a joint R&D programme, collaborative R&D projects, deployment and piloting activities, input to regulatory aspects and co-creation of solutions with end-users. Out of 61 respondents, 49 (80.33%) indicated that co-creation of solutions

with end users were very relevant to ensure that the Partnership would meet its objectives. For all the other options, the majority (over 50%) of all respondents have indicated that these are very relevant. Respondents have answered 5 (fully relevant) the least in regard to deployment and piloting activities, although still 51,62% of respondents have given this answer. See Figure 27.

No statistical differences were found between the views of citizens and other respondents.

Figure 7: Views of respondents on relevance of implementation of the following activities

Relevance of a legal structure (funding body) to achieve specific objectives

Respondents were also asked to assess the relevance of a specific legal structure (funding body) for the candidate European Partnership to achieve several activities. According to Figure 28, respondents indicated that it was very relevant to set up a specific legal structure for the partnership to ensure harmonisation of standards and approaches (40, 64.52%), followed by the need to ensure better links with regulators (36, 58%). The implementation of activities more effectively is deemed relevant (21 respondents) or very relevant (32 respondents). The relevance of a specific legal structure to facilitate collaboration with other Partnerships is deemed the least relevant, as this question has received the most answers in category 3 of the 5 point relevance scale (20,97%) and the least 5 (very relevant) answers (24, 38.71%) of all the questions.

No statistical differences were found between the views of citizens and other respondents.

Figure 8: Views of respondents on relevance of a specific legal structure

Scope and coverage of the candidate European Partnership

Respondents were asked to assess the scope and coverage of the Integrated Air Traffic Management, based on its inception impact assessment. The clear majority of the respondents have indicated that the partnership has the right scope and coverage across all areas. The respondents have been the most positive with regard to technologies covered, where 46 respondents (75.41%) have indicated the partnership has the right scope and coverage. Respondents found that the sectoral scope and coverage was right, the least often, while still over 56% of the respondents has indicated that it was the right scope. On average, the respondents who have indicated that the scope and coverage are too narrow, have done so as they feel that airspace users should be more involved in the new partnership than is the case today.

No statistical differences were found between the views of citizens and other respondents.

Figure 9: Views of respondents on the scope and coverage proposed for the Integrated Air Traffic Management Partnership

Aside from this multiple choice question, the respondents were also asked to provide any comment that they may have on the proposed scope and coverage for this candidate Institutionalised Partnership. Several responses (about 10 out of 34) mention the need for higher involvement of end-users, i.e. airspace users in the programme, taking into account their diversity (e.g. schedule, cargo, business airlines, general aviation). Several respondents just clarified that the assessment of scope and coverage was based on the current partnership, as they have not seen the proposal for the future partnership. Some stakeholders stated that the membership of the current partnership was not open to new entrants. The current partnership was mentioned as a good starting point for the future partnership. Furthermore, the need to reach sustainability goals was mentioned.

Alignment of the European Partnership with other initiatives

The respondents were also asked if they thought it would be possible to rationalise the candidate European Institutionalised Partnership and its activities, and/or to better link it with other comparable initiatives – 37 respondents (66.07%) have indicated that they think this is the case, 19 respondents (29%) have stated no (10 interviewees offered no responses).

No statistical differences were found between the views of citizens and other respondents.

The respondents who answered affirmative, were asked which other comparable initiatives it could be linked with. Thirteen respondents indicated that the Partnership should be linked to Clean Sky partnership. Several responses further stated that there should be no rationalisation, or that it was not clear what was meant by rationalisation. Key Digital Technologies and Smart Networks and Services initiatives were also mentioned as candidates for synchronisation and strong synergies.

For the respondents who answered negatively on the previous question, respondents feel that there is almost no overlap on content of this initiative with other initiatives, but clear interfaces exist. According to them ATM R&I need very specific partners and expertise, and while it is already extremely complex, it must stay manageable.

Relevance of the Candidate European Partnership to deliver impacts

Respondents were asked to assess the relevance of the candidate European Institutionalised Partnership to deliver on listed impacts. According to Figure 33, the candidate Partnership is expected to be ‘very relevant’ for increasing aviation safety levels for all types of flying vehicles and for improving passenger experience by reducing travel time, delays and costs. In contrast, the impact on education of the next generation of aviation professionals and encouragement of diversity and inclusion is expected to be lower, as only 27 out of 62 respondents (43.55%) consider that the Partnership would be ‘very relevant’ for this, but further 39% of respondents find it relevant. Among listed economic/technological impacts, over 60% of respondents indicated that the candidate Partnership is relevant to achieve an impact on EU aviation industry competitiveness, on customer experience & opportunities by reduced travel time, management costs and improved predictability, and on the number of disruptions caused by cyber-security vulnerabilities. The pattern of responses about the scientific impacts are similar, however, a smaller number of respondents (about 40%) consider that the Partnership would have a very relevant effect on generation of new scientific knowledge and reinforcement of EU scientific capabilities, while further 30% of respondents find it relevant.

No statistical differences were found between the views of citizens and other respondents, except for the economic/technological impact related to the creation of additional jobs in the air transport industries and the EU economy at large which citizens found less relevant.

Figure 10: Views of respondents on the relevance of the candidate European Institutionalised Partnership to various impacts

Annex 3 Who is affected and how?

1. PRACTICAL IMPLICATIONS OF THE INITIATIVE

The proposed ATM R&I partnership aims to develop the technology needed to address the emerging challenges in the air traffic management sector, making the European airspace the most efficient and environmentally friendly sky to fly in the world. It will produce quantifiable contributions towards achieving two of the Commission's top priorities: the "European Green Deal" and a "Europe fit for the digital age" while supporting robust economic recovery of Europe and its hardly hit aviation sector after the COVID 19 crisis.

The following stakeholder groups are affected by the proposed initiative, as explained below:

- An aviation infrastructure that opens up digital opportunities for people and business and enhance Europe's position as a world leader in the digital economy will have a positive impact on private stakeholders across the whole aviation value chain. In particular airborne and ground system manufactures, air navigation and data service providers, airports and aircraft operators. This includes a number of European start-ups, SMEs and innovators that are challenging the status-quo in the field of drone technology.
- European universities and research-based organisations will play a pivotal role to increase the scientific knowledge base and contribute to accelerate the development of aviation innovations through collaboration with private enterprises.
- Citizens and the society will benefit from reduced emissions and noise as well as improved mobility by losing less time in airports and in the air, allowing European passengers to spend an additional 14.5 million hours currently lost with delays with their families or at work.
- Finally, in an increasingly globalized and interlinked world, there is pressure on policy makers and regulators to deliver rapid, functioning solutions to address climate change. The proposed Partnership will be instrumental in providing the relevant scientific and technology evidence in aviation to support those choice sand facilitating interactions between breakthrough innovators and early movers to help develop regulatory frameworks that allow the benefits of digital technologies to be fully realised.

2. SUMMARY OF COSTS AND BENEFITS

<i>I. Overview of Benefits (total for all provisions) – Preferred Option</i>		
<i>Description</i>	<i>Amount</i>	<i>Comments</i>
<i>Direct benefits</i>		
Improve the Ability to handle additional flights enabling	Direct benefits of ATM value chain	Full scalability : creates the capacity needed to handle traffic in the most efficient way

growth in air transport	Cumulative Benefit up to 2050: EUR 510bn	where and when capacity is needed. Safety: better trained humans using new technologies will increase safety beyond the current (already high) levels.
Enable new economic activity based on drones	Direct benefits of the U-space value chain Cumulative Benefit up to 2050: EUR 350bn	U-space and urban air mobility: A digitally native traffic management system will ensure the safe and secure integration of drones in the airspace especially in urban areas, taking into account new and existing air vehicles and autonomous operations. One of the most challenging use cases from U-space will be to enable urban air mobility, which is expected to advance autonomous technologies in a number of areas.
Boost EU industry globally through international agreements and the setting of global standards	Grow market share to 70% of the global market of approximately €4b per annum Cumulative Benefit up to 2050: EUR 84bn	Leadership of Europe in the world: Europe is currently the world leader in aerospace and aviation infrastructure technology. Unless this opportunity is taken it is likely that Europe will lose its leadership position and become more dependent on imports from third countries.
Reducing aviation noise and gas emissions	Reduction of 240 kg to 450 kg of CO ₂ on average per flight due to improved flight efficiency Cumulative Benefit in terms of fuel savings up to 2050: EUR 12bn	Zero environmental waste: eliminates environmental inefficiencies caused by the aviation infrastructure, ensuring that it offers solutions that will fully exploit the potential offered by the next generation aircraft for cleaner and quieter flight. A digital European sky could save 28 million CO ₂ tonnes per year, which is roughly equivalent to CO ₂ produced by 3.2 million people or the population in the metropolitan area of a city like Madrid.
Indirect benefits		
Improve passenger experience by reducing travel time, delays and costs	Indirect benefits for passengers and EU citizens. Cumulative Benefit up to 2050: EUR 760bn	A digital and optimally managed European sky will ensure that passengers do not lose time at airports or in the air in Europe. In doing so, it could save yearly up to 14.5 million hours that passengers will be able to spend instead with their family or at work.

(1) Estimates are relative to the baseline for the preferred option as a whole (i.e. the impact of individual actions/obligations of the preferred option are aggregated together); (2) Please indicate which stakeholder group is the main recipient of the benefit in the comment section;(3) For reductions in regulatory costs, please describe details as to how the saving arises (e.g. reductions in compliance costs, administrative costs, regulatory charges, enforcement costs, etc.; see section 6 of the attached guidance).

- (2) Estimates assume the successful roll-out into operations of the results of R&D as defined in the European ATM Master Plan which will be coordinated by the future partnership but will depend also on the evolution of the supporting regulatory framework which is outside of the direct control of the future partnership.
- (3)

II. Overview of costs – Preferred option							
		Citizens/Consumers		Businesses		Administrations	
		One-off	Recurrent	One-off	Recurrent	One-off	Recurrent
Administrative Costs, including Personnel	Direct costs				EUR 6.1million (annual contribution for admin costs, jointly paid by the current 19 private partners + Eurocontrol)		EUR 3.3million (Union's annual contribution for administrative costs, including 39 FTEs)
	Indirect costs						
Action (b)	Direct costs						
	Indirect costs						

REFIT Cost savings table

Not applicable for the proposed ATM Partnership. The initiative will benefit from the existing organisation/structure (e.g. the Programme Office) already in place for the SESAR JU. There are no additional regulatory costs associated, and no specific simplification measures apply in this case.

Annex 4 Analytical Methods

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines¹³ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This is complemented by integrating the **conditions and selection criteria for European Partnerships**, as well as requirements for setting up Institutionalised Partnerships.¹⁴

1. OVERVIEW OF THE METHODOLOGIES EMPLOYED

In terms of **methods and evidence used**, the set of impact assessments for all candidate Institutionalised European Partnerships draw on an external study covering all initiatives in parallel to ensure a high level of coherence and comparability of analysis¹⁵.

All impact assessment mobilised a mix of qualitative and quantitative data collection and analysis methods. These methods range from desk research and interviews to the analysis of the responses to the Open Consultation, stakeholder analysis and composition/portfolio analysis, bibliometrics/patent analysis and social network analysis, and a cost-effectiveness analysis.

The first step in the impact assessment studies consisted in the definition of the context and the problems that the candidate partnerships are expected to solve in the medium term or long run. The main data source in this respect was desk research. This includes grey and academic literature to identify the main challenges in the scientific and technologic fields and in the economic sectors relevant for the candidate partnerships, as well as the review of official documentations on the policy context for each initiative.

In the assessment of the problems to address, the lessons to be learned from past and ongoing partnerships were taken into account, especially from relevant midterm or ex-post evaluations.

The description of the context of the candidate institutionalised European Partnerships required a good understanding of the corresponding research and innovation systems and their outputs already measured. Data on past and ongoing Horizon 2020 projects, including the ones implemented through Partnerships, served as basis for descriptive statistic of the numbers of projects and their respective levels of funding, the type of organisations participating (e.g. universities, RTOs, large enterprises, SMEs, public administrations, NGOs, etc.) and how the funding was distributed across them. Special attention was given to analysing the participating countries (and groups of countries, such as EU, Associated Countries, EU13 or EU15) and industrial sectors, where relevant. The sectoral analysis required enriching the eCORDA data received from the European Commission services with sector information extracted from ORBIS, using the NACE codification up to level 2. These data enabled the identification of the main and, where possible, emerging actors in the relevant systems, i.e. the organisations, countries and sectors that would need to be involved (further) in a new initiative.

¹³ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

¹⁴ A pivotal element of the present analysis is the so-called two-step 'necessity test' for European Partnerships, used to establish: step 1) the need for a partnership approach in the first place, followed by step 2) a justification for the form of Institutionalised Partnership. The necessity test is described in Annex 6. This impact assessment focuses on the second step of the test.

¹⁵ Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe

A Social Network Analysis was performed by the contractors using the same data. It consisted in mapping the collaboration between the participants in the projects funded under the ongoing R&I partnerships. This analysis revealed which actors – broken down per type of stakeholders or per industrial sector – collaborate the most often together, and those that are therefore the most central to the relevant research and innovation systems.

The data provided finally served a bibliometric analysis run by the contractor aimed at measuring the outputs (patents and scientific publications) of the currently EU-funded research and innovation projects. A complementary analysis of the Scopus data enabled to determine the position and excellence of the European Union on the international scene, and identify who its main competitors are, and whether the European research and innovation is leading, following or lagging behind.

A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options.

The conclusions drawn from the data analysis were confronted to the views of experts and stakeholders collected via three means:

- The comments to the inception impact assessments of the individual candidate institutionalised European Partnerships;
- The open public consultation organised by the European Commission from September to November 2019;
- The interviews (up to 50) conducted by each impact assessment study team conducted between August 2019 and January 2020 (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others).

The views of stakeholders (and experts) were particularly important for determining the basic functionalities (see further below) that the future partnerships need to demonstrate to achieve their objectives as well as their most anticipated scientific, economic and technological, and societal impacts. The interviews allowed more flexibility to ask the respondents to reflect about the different types of European Partnerships. Furthermore, as a method for targeted consultation, it was used to get insights from the actors that both the Study Teams and the European Commission were deemed the most relevant. For the comparative assessment of impacts, the external contractors confronted the outcomes of the different stakeholder consultation exercises to each other with a view of increasing the validity of their conclusions, in line with the principles of triangulation.

Annex 2 includes also the main outcomes of the stakeholder consultation exercises.

2. METHOD FOR ASSESSING THE EFFECTIVENESS, EFFICIENCY AND COHERENCE OF EACH OPTION - THE USE OF FUNCTIONALITIES

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has been adapted to introduce “**key functionalities needed**” – so as to link the intended objectives of the candidate European Partnerships and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is

based on the distinguishing factors between the different options (see Section 2.2.1 in the main body of the impact assessment). In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved ('openness'), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options. It also allows for a structured comparison of the options as regards their effectiveness, efficiency and coherence, and also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)¹⁶.

Figure 3 Overview of key functionalities of each form of implementation of European Partnerships

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
Type and composition of actors (including openness and roles)				
<u>Partners:</u> N.A., no common set of actors that engage in planning and implementation <u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> core of national funding bodies or governmental research organisations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> limited, according to national rules of partner countries	<u>Partners:</u> National funding bodies or governmental research organisation <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations
Type and range of activities (including additionality and level of integration)				
<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions <u>Additionality:</u> no additional activities and investments outside the funded projects <u>Limitations:</u> No systemic approach beyond individual actions	<u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake <u>Additionality:</u> Activities/investments of partners, National funding <u>Limitations:</u> Limited systemic approach beyond individual actions.	<u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake <u>Additionality:</u> National funding <u>Limitations:</u> Scale and scope depend on the participating programmes, often smaller in scale	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach <u>Additionality:</u> National funding	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds). <u>Additionality:</u> Activities/investments of partners/ national

¹⁶ The criterion on the ex-ante demonstration of partners' long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
				funding
Directionality				
<u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years. <u>Limitations:</u> Fully taking into account existing or to be developed SRIA/roadmap	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Input to FP annual work programme drafted by partners, finalised by COM (comitology) Objectives and commitments are set in the contractual arrangement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the Grant Agreement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the legal base.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM (veto-right in governance) Objectives and commitments are set in the legal base.
Coherence: internal (Horizon Europe) and external (other Union programmes, national programmes, industrial strategies)				
<u>Internal:</u> Between different parts of the Annual Work programme can be ensured by COM <u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Limited synergies with other Union programmes and industrial strategies If MS participate, with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with other Union programmes and industrial strategies If MS participate, with national/regional programmes and activities

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made in comparison to the baseline. Therefore, for each of the above criteria, the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. When relevant, this estimation also includes the costs/benefits of discontinuing existing implementation structures. The policy options are then scored compared to the baseline with a + and – system along a two-point scale, to indicate limited (+ or -) or high (++ or --) additional/lower performance compared to the baseline. When a policy option is scored 0, this means that its impact is expected to be roughly equal to the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options¹⁷.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach¹⁸ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account¹⁹. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs of each candidate initiative.²⁰ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

¹⁷ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

¹⁸ For further details, see Better Regulation Toolbox # 57.

¹⁹ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

²⁰ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership the costs of preparation and implementation increase only marginally compared to the baseline (<1%),²¹ but lead to an additional R&I investment of at least the same amount than the Union contribution²² (efficiency of 98% for the overall investment).
- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2,3 times the Union contribution²³. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).²⁴
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution²⁵. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution²⁶. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0		↑↑		
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0		↑↑		
Ex-ante Impact Assessment for partnership		0		↑↑↑	
Preparation of EC proposal and negotiation		0		↑↑↑	

²¹ Specifically, some additional set-up costs linked for example to the creation of a strategic research and innovation agenda (SRIA) and additional running costs linked with the partners role in the creation of the annual work programmes and the Commission's additional supervisory responsibilities. A CPP will have lower overall costs than each of the other types of European Partnership, as it will function with a smaller governance and implementation structure than will be required for a Co-Funded Partnership or an Institutionalised Partnership and – related to this – its calls will be operated through the existing HEU agencies and RDI infrastructure and systems.

²² Minimum contributions from partners equal to the Union contribution.

²³ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

²⁴ These costs reflect set-up costs and additional running costs for partners, and the Commission, of the distributed, multi-agency implementation model.

²⁵ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

²⁶ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0		↑		
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC			0		↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**). In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

More specifically for the ATM partnership, building on the assumptions outlined in Figure 4 and the known real costs, e.g. from the current SESAR JU implementation, the additional costs compared to the baseline are about 6-7% of the Union’s contribution. When considering the fact that over 60% of these administrative costs are covered by private and inter-governmental partners (i.e. Eurocontrol), re-establishing the JU is roughly similarly efficient to the baseline scenario (96%-97%), and only one percentage point behind in efficiency to the co-programmed partnership. Considering the fact that the Art 187 initiative has the highest ability to deliver the highest expected impacts, it delivers the best value for the Union budget investment.

3. METHOD FOR IDENTIFYING THE PREFERRED OPTION – THE SCORECARD ANALYSIS

For the **identification of the preferred option**, a scorecard analysis is used to build a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

This scorecard approach also relies on a standard cost model developed for the external study supporting the impact assessment, as illustrated in **Error! Reference source not found..** Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**). In carrying out the scoring of options, the

results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

These costs essentially refer to the administrative, operational and coordination costs of the various options. The figure shows how the scoring of costs range from a value of 0, in case an option does not entail any additional costs compared to the baseline (traditional calls), to a score of (-) for options introducing limited additional costs relative to the baseline and a score of (- -) when substantial additional costs are expected in comparison with the baseline. Should the costs of a policy option be lower than those of the baseline, (+) and (+ +) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. A score of + is therefore assigned for **cost-efficiency** to the Co-Programmed and Co-Funded options, a score of 0 to the Article 185 option and a score of (-) for the Article 187 Institutionalised Partnership policy option²⁷.

Figure 5: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Co- funded	Option 3a: Institutionalised 185	Option 3b: Institutionalised 187
Administrative, operational and coordination costs	0	(0)	(-)	(- -)	(- -)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. <i>cost-efficiency</i>)	0	(+)	(+)	(0)	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared to baseline; score (- -) = substantial additional costs compared to baseline. ; score (+) = lower costs compared to baseline

²⁷ The baseline (traditional calls) is scored 0, as explained above.

1. Can the Union act? What is the legal basis and competence of the Unions' intended action?
1.1 Which article(s) of the Treaty are used to support the legislative proposal or policy initiative?
<p>This proposal is based on (1) Article 185 TFEU which stipulates that in implementing the multiannual framework programme, the Union may make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; and (2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes (both Articles are under Title XIX of the TFEU - Research and Technological Development and Space).</p> <p>The proposal aims to implement Article 8 of the Commission proposal for Horizon Europe - the future EU research and innovation (R&I) programme for 2021-2027, according to which, “<i>European Partnerships shall be established for addressing European or global challenges only in cases where they will more effectively achieve objectives of Horizon Europe than the Union alone and when compared to other forms of support of the Framework programme</i>”. The Horizon Europe proposal has received the political agreement of the Council and the European Parliament.</p>
1.2 Is the Union competence represented by this Treaty article exclusive, shared or supporting in nature?
<p>Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the European Union can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas.</p> <p><i>Subsidiarity does not apply for policy areas where the Union has exclusive competence as defined in Article 3 TFEU²⁸. It is the specific legal basis which determines whether the proposal falls under the subsidiarity control mechanism. Article 4 TFEU²⁹ sets out the areas where competence is shared between the Union and the Member States. Article 6 TFEU³⁰ sets out the areas for which the Unions has competence only to support the actions of the Member States.</i></p>

²⁸ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E003&from=EN>

²⁹ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E004&from=EN>

³⁰ <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:12008E006:EN:HTML>

2. Subsidiarity Principle: Why should the EU act?

2.1 Does the proposal fulfil the procedural requirements of Protocol No. 2³¹:

- Has there been a wide consultation before proposing the act?
- Is there a detailed statement with qualitative and, where possible, quantitative indicators allowing an appraisal of whether the action can best be achieved at Union level?

This proposal and the accompanying impact assessment were supported by a wide consultation of stakeholders, both during the preparation of the Horizon Europe proposal and - later on, all the candidates for European Partnerships. Member States were consulted via the Shadow Strategic configuration of the Horizon Europe Programme Committee. On candidates for institutionalised Partnerships based on Article 185/187 of the TFEU, an Open Public Consultation (OPC) was held between 11 September and 6 November 2019. Over 1 600 replies were received. In addition, targeted consultation activities were undertaken to prepare the present impact assessment. In particular, for each of the candidate partnerships, an external consultant interviewed a representative sample of stakeholders. The need for EU action as well as its added value were covered in those interviews.

The explanatory memorandum and the impact assessment (horizontal part, Section 3) contain a dedicated section on the principle of subsidiarity, as explained in question 2.2 below.

2.2 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the conformity with the principle of subsidiarity?

The impact assessment accompanying the proposal features a horizontal part on relevant common elements to all the candidate partnerships, including the conformity of the proposed initiative with the principle of subsidiarity (Section 3). Moreover, the individual assessments of each candidate partnership include additional details on subsidiarity, touching in particular on the specificities of a candidate partnership that could not be adequately reflected in the horizontal part of the impact assessment. This will also be reflected in the explanatory memorandum.

2.3 Based on the answers to the questions below, can the objectives of the proposed action be achieved sufficiently by the Member States acting alone (necessity for EU action)?

National action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives, to deliver on the EU's strategic policy priorities (including the climate and energy goals set out in the Paris Agreement, and the European Green Deal), and to contribute to tackling global challenges and meeting the

³¹ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12016E/PRO/02&from=EN>

Sustainable Development Goals (SDGs).

(a) Are there significant/appreciable transnational/cross-border aspects to the problems being tackled? Have these been quantified?

The thematic areas covered by the candidate partnerships feature a series of challenges in terms of cross-border/transnational aspects, need to pool resources, need for a critical mass to meet intended policy objectives, need to coordinate different types of actors (e.g. academia, industry, national and regional authorities) across different sectors of the economy and society, which cannot be tackled to the same degree by Member States alone. This is particularly true for the research and innovation (R&I) dimension of the proposed initiative: the importance of a multi-centre and interdisciplinary approach, cross-country data collection and research, and the need to develop and share new knowledge in a timely and coordinated manner to avoid duplication of efforts are key to achieve high quality results and impact. The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide extensive qualitative and quantitative evidence on the above points. In addition, Sections 1 and 2 of the individual impact assessments on the candidate partnerships include more detail on the necessity to act at EU-level in specific thematic areas. Finally, it is worth noting that not all Member States have the same capacity or R&I intensity to act on these challenges. As the desired policy objectives can be fully achieved only if the intended benefits are widespread across the Member States, this requires action at the EU-level.

(b) Would national action or the absence of the EU level action conflict with core objectives of the Treaty³² or significantly damage the interests of other Member States?

As per Article 4(3) TFEU, national action does not conflict with core objectives of the Treaty in the area of R&I. The absence of EU level action in this area would however prevent the achievement of core objectives of the Treaty. Indeed, national action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives on e.g. competitiveness, to deliver on the EU's strategic policy priorities, and to contribute to tackling global challenges and meet the Sustainable Development Goals (SDGs).

(c) To what extent do Member States have the ability or possibility to enact appropriate measures?

As foreseen by Article 4(3) TFEU, this proposal does not hamper Member States' ability to enact appropriate measures in the field of R&I. However, the scale and complexity of the policy objectives pursued by the present initiative cannot be fully addressed by acting at national level alone.

(d) How does the problem and its causes (e.g. negative externalities, spill-over effects)

³² https://europa.eu/european-union/about-eu/eu-in-brief_en

<p>vary across the national, regional and local levels of the EU?</p>
<p>As described in the horizontal part of the impact assessment accompanying the present proposal, several problems (e.g. on competitiveness, global challenges, demographic change) and their underlying causes affect the EU as a whole rather than individual Member States. Where important differences between Member States are present, these are described in Sections 1 and 2 of the individual impact assessments.</p>
<p>(e) Is the problem widespread across the EU or limited to a few Member States?</p>
<p>The problem of coordinating R&I efforts in the thematic areas covered by the candidate partnerships affects all Member States, albeit to different degrees. However, from a general EU perspective, available evidence shows that the EU as a whole needs to step up efforts and investments in thematic areas that are crucial to tackle present and future policy challenges on several fronts, e.g. ageing population, global technological trends, and climate change to name a few. The way these problems affect the EU and its Member States is described in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual impact assessments.</p>
<p>(f) Are Member States overstretched in achieving the objectives of the planned measure?</p>
<p>As indicated in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual assessments, the sheer scale, speed and scope of the needed support to R&I would overstretch national resources, without guaranteeing the achievement of the intended objectives. Acting at EU-level would achieve greater impact in a more effective and efficient manner.</p>
<p>(g) How do the views/preferred courses of action of national, regional and local authorities differ across the EU?</p>
<p>No specific differences between the views of national, regional and local authorities emerged from the stakeholder consultation.</p>
<p>2.4 Based on the answer to the questions below, can the objectives of the proposed action be better achieved at Union level by reason of scale or effects of that action (EU added value)?</p>
<p>EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national initiatives in the same area.</p>

(a) Are there clear benefits from EU level action?

Quantitative and qualitative evidence of the benefits of EU level action are available in the interim evaluation of Horizon 2020 and in the impact assessment of Horizon Europe, among others. An analysis of the emerging challenges in each thematic areas, of the EU's competitive positioning, as well as feedback gathered from different types of stakeholders for the present impact assessment indicate that EU level action remains appropriate also for the present proposal. In addition, the benefits of acting at EU-level have been illustrated by the success and the impact achieved by the predecessors to the proposed initiative.

(b) Are there economies of scale? Can the objectives be met more efficiently at EU level (larger benefits per unit cost)? Will the functioning of the internal market be improved?

EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. This is the case both in terms of effectiveness in achieving intended policy objectives, but also in terms of efficiency. Positive impact is also visible in terms of competitiveness: recent data on EU funded R&I activities indicate that EU-funded teams grow 11.8% faster and are around 40% more likely to be granted patents or produce patents applications than non-EU funded teams. Efficiency gains are also visible in terms of dissemination of results to users beyond national borders, including SMEs and citizens. EU funded R&I is more effective in leveraging private investment. Finally, there are clear additionality benefits (i.e. EU R&I funding does not displace or replace national funding), as the EU focuses on projects that are unlikely to be funded at national or regional level. Overall, this is beneficial to the functioning of the internal market in several respects, including human capital reinforcement through mobility and training, the removal of barriers to cross-border activity for economic players including SMEs, easier access to finance and to relevant knowledge and research, and increased competition in the area of R&I.

(c) What are the benefits in replacing different national policies and rules with a more homogenous policy approach?

A homogeneous policy approach in the various thematic areas covered by the present proposal would reduce fragmentation and increase efficiency and effectiveness in meeting the intended policy objectives. Indeed fragmentation, persisting barriers in the internal market and differences in the resources available to Member States are some of the key problems that stand in the way of fully achieving the intended policy objectives and reaching the required critical mass to obtain tangible results. Specific detail on how these issues differ in each thematic area are illustrated in Sections 1 and 2 of the individual impact assessments, so as to reflect the specificities of each case.

(d) Do the benefits of EU-level action outweigh the loss of competence of the Member States and the local and regional authorities (beyond the costs and benefits of acting at

<p>national, regional and local levels)?</p>
<p>The proposed initiative does not lead to a loss of competence of the Member States. In fact, the proposed initiative should be seen as complementary and reinforcing national and sub-national initiatives in the same area. Previous quantitative and qualitative assessments of Horizon Europe and Horizon 2020 have shown that the proposed EU-level action do not displace national ones and tend to concentrate on initiatives that would not have been funded by the Member States themselves, or would not have reached the same scale and ambition without EU-level intervention, due to their complexity and trans-national nature.</p>
<p>(e) Will there be improved legal clarity for those having to implement the legislation?</p>
<p>Yes. The proposed initiatives will be implemented in line with the Horizon Europe single set of rules for participation; this will ensure increased clarity and legal certainty for end beneficiaries, other stakeholders and programme administrators. It will also reduce the administrative burden for beneficiaries, and for the Commission services. In addition, the accessibility and attractiveness of the broader Horizon Europe programme, in particular for applicants with limited resources, would be sustained.</p>
<p>3. Proportionality: How the EU should act</p>
<p>3.1 Does the explanatory memorandum (and any impact assessment) accompanying the Commission’s proposal contain an adequate justification regarding the proportionality of the proposal and a statement allowing appraisal of the compliance of the proposal with the principle of proportionality?</p>
<p>The principle of proportionality underpins the entire analysis of the candidate partnerships. Specifically, the analysis included in the accompanying impact assessment is structured along the following logic: 1. Justification of the use of a partnership approach in a given area (including considerations on additionality, directionality, link with strategic priorities) instead of other forms of intervention available under Horizon Europe; 2. If the partnership approach is deemed appropriate, proportionality considerations guide the assessment of which type of partnership intervention (collaborative calls, co-programmed, co-funded or institutionalised partnership) is most effective in achieving the objectives. This will also be reflected in the explanatory memorandum.</p>
<p>3.2 Based on the answers to the questions below and information available from any impact assessment, the explanatory memorandum or other sources, is the proposed action an appropriate way to achieve the intended objectives?</p>
<p>The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the present proposal leaves full freedom to the Member States to</p>

pursue their own actions in the policy areas concerned. This will also be reflected in the explanatory memorandum.

(a) Is the initiative limited to those aspects that Member States cannot achieve satisfactorily on their own, and where the Union can do better?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments.

(b) Is the form of Union action (choice of instrument) justified, as simple as possible, and coherent with the satisfactory achievement of, and ensuring compliance with the objectives pursued (e.g. choice between regulation, (framework) directive, recommendation, or alternative regulatory methods such as co-legislation, etc.)?

For each of the candidate partnerships, the analysis carried out in the accompanying impact assessment has explored several options for implementation. A comparative assessment of the merits of each option also included an analysis of the simplicity of the intervention, its proportionality and effectiveness in achieving the intended objectives. This is reflected in the fact that a tailored approach has been suggested for each candidate partnership, ranging from looser forms of cooperation to more institutionalised ones, depending on the intended policy objectives, specific challenges, and desired outcome identified in each case.

(c) Does the Union action leave as much scope for national decision as possible while achieving satisfactorily the objectives set? (e.g. is it possible to limit the European action to minimum standards or use a less stringent policy instrument or approach?)

The proposed approach leaves full freedom to the Member States to pursue their own actions in the policy areas covered by the present proposal.

(d) Does the initiative create financial or administrative cost for the Union, national governments, regional or local authorities, economic operators or citizens? Are these costs commensurate with the objective to be achieved?

The proposed initiatives do create financial and administrative costs for the Union, national governments and, depending on the chosen mode of implementation, for regional and local authorities. In addition, economic operators and other stakeholders potentially involved in the candidate partnerships will also incur some costs linked to implementation. The financial cost of the proposed initiative is covered under the Horizon Europe programme. Its exact amount is still subject to political decision. As regards the candidate partnerships and the different modes of implementation (co-programmed, co-funded, institutionalised), the relevant costs and benefits are assessed in the individual impact assessments covering each candidate partnership. The additional administrative costs of implementation via partnerships are

limited, when compared to the administrative costs of implementation through traditional calls. As indicated by comparable experience with previous initiatives and in feedback provided by a variety of stakeholders, these costs are expected to be fully justified by the benefits expected from the proposed initiative. Where available, additional details on costs are provided in Annex 3 of the impact assessment.

(e) While respecting the Union law, have special circumstances applying in individual Member States been taken into account?

Where relevant, differences between Member States in capacity and stage of advancement of R&I in specific thematic areas have been taken into account in the individual impact assessments.

Annex 6 Additional background information

1. BACKGROUND INFORMATION FOR ALL INITIATIVES

1.1. Selection criteria of European Partnerships

Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

The necessity test for a European Partnership (as set out in the Horizon Europe regulation) has two levels:

1. **The justification for implementing a priority with a European Partnership** to address Horizon Europe and EU priorities. This is linked to demonstrating that a European Partnership can produce added value beyond what can be achieved through other Framework Programme modalities, notably traditional calls in the work programmes (Option 0 – Baseline).
2. **The justification for the use of the form of Institutionalised Partnership:** Once it has been demonstrated that a partnerships approach is justified, co-programmed and/or co-funded forms are considered for addressing the priorities as they are administratively lighter, more agile and easier to set-up (Options 1 and/or 2). As Institutionalised Partnerships require setting up a legal framework and the creation of a dedicated implementation structure, they have to justify higher set-up efforts by demonstrating that it will deliver the expected impacts in a more effective and efficient way, and that a long-term perspective and high degree of integration is required (Option 3).

The outcomes of the ‘necessity test’ is presented together with the preferred option.

Figure 5 Horizon Europe selection criteria for the European Partnerships

Common selection criteria & principles	Specifications
1. More effective (Union added value) clear impacts for the EU and its citizens	Delivering on global challenges and research and innovation objectives
	Securing EU competitiveness
	Securing sustainability
	Contributing to the strengthening of the European Research and Innovation Area
	Where relevant, contributing to international commitments

Common selection criteria & principles	Specifications
2. Coherence and synergies	Within the EU research and innovation landscape
	Coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions
3. Transparency and openness	Identification of priorities and objectives in terms of expected results and impacts
	Involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness
	Clear modalities for promoting participation of smes and for disseminating and exploiting results, notably by smes, including through intermediary organisations
4. Additionality and directionality	Common strategic vision of the purpose of the European Partnership
	Approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level
	Demonstration of expected qualitative and significant quantitative leverage effects, including a method for the measurement of key performance indicators
	Exit-strategy and measures for phasing-out from the Programme
5. Long-term commitment of all the involved parties	A minimum share of public and/or private investments
	In the case of institutionalised European Partnerships, established in accordance with article 185 or 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments

1.2. Overview of potential functions for a common back office among Joint Undertakings

Functions	Current situation	Option of joint back-office	Comments
Organising calls for grant and proposal evaluations	Each JU organises this independently.	A central organisation of evaluation, logistics, contracting evaluators, managing the data of the evaluation results Central database of potential evaluators with domain expertise in thematic areas of partnerships	The evaluations would still need to be supervised by the Scientific staff of the individual Joint Undertakings (consensus meetings of expert evaluators etc)
Human Resources related matters	Each JU has own HR policy and resources Quite some resources spent on recruitment in some JUs	More generic resources and expertise for HR matters More consistency in HR	Ensuring consistency with EC HR policies is already in place

	Some HR facilities are procured from external contractors Some JUs have a Service Level Agreement with COM for HR	policy Shared HR investment for specialised expertise (IP and legal)	
Financial management	Each JU conducts own financial contract management; differences between JUs Each JU is audited separately. Auditing at project level more frequent than in other Horizon 2020 parts and outsourced by JUs thus differences ECA: too many audits on JUs	Financial management by one core team of financial staff Would reduce the number of interfaces for audits and simplifies the auditing of the all JUs Harmonisation of project auditing	Simplifies the harmonisation of financial management across JUs in line with Horizon Europe
Communication (internal and external)	Each JU has a separate communication strategies, teams and resources	A common back-office can support activities such as event organisation, dissemination of results, setting up website communication Can help create a more visible Partnership brand	A considerable share of communication activity is partnership specific (addressing particular target groups, synthesising project results) however there are generic communication activities that can be shared Needs to avoid duplication of efforts
Data management on calls, project portfolios, information on project results	Most JUs but not all use e-Corda for project data Overall IT integration of JUs still difficult	Harmonised data management Reduction of IT systems and support that is procured	This will need to happen regardless of the common back office but will likely be more smooth if managed centrally

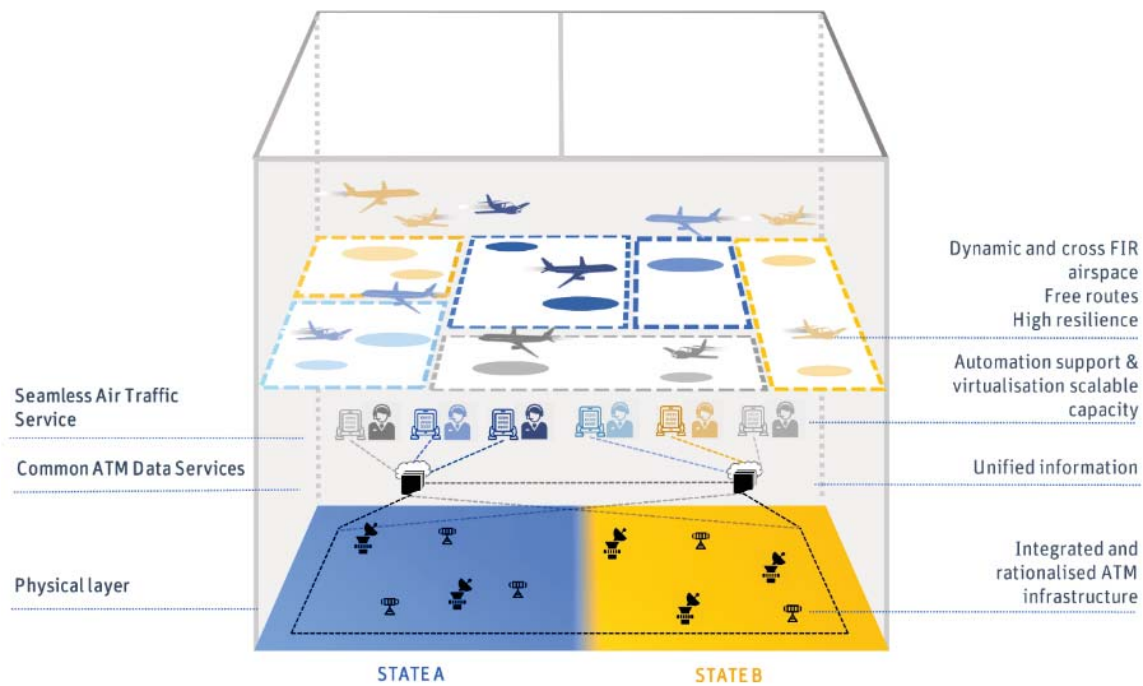

2. BACKGROUND INFORMATION FOR THIS SPECIFIC INITIATIVE

2.1. European ATM Master Plan – scenarios and economic impacts

Future R&I Needs

The European ATM Master Plan defines the vision for the digital transformation of ATM infrastructure. The vision was developed to accelerate modernisation of ATM using an architectural approach that brings together the airspace, operations and infrastructure in a harmonised manner across the EU. The main principles of this architecture are shown in Figure 6.

Figure 6: Proposed Future Architecture

Source: A proposal for the future architecture of the European airspace, SJU, 2019.

The proposal is based on a number of key transformations that require R&I as defined in Table 2. The R&I needs are a step change to the current programme: rather than focussing on contained individual ATM solutions that support marginal performance improvement of specific functions the need is now to focus on a small number of breakthrough technologies that together create a step change in overall system performance.

Table 2: Key transformations to achieve the future airspace architecture

Key Transformations		
	<p>Connected and automated ATM</p>	<p>The future ATM system will deliver hyper connectivity between all stakeholders (vehicle-to-vehicle, vehicle-to-infrastructure) via high bandwidth, low latency fixed and mobile networks. Highly automated systems with numerous actors will interact with each other seamlessly, with fewer errors making the system scalable and even safer than today.</p>

	Air-ground integration and autonomy	The progressive move towards autonomous flying enabled by self-piloting technologies requires a closer integration between vehicle and infrastructure capabilities so that the infrastructure can act as a digital twin of the aircraft.
	AI for aviation	Tomorrow's aviation infrastructure will be more data intensive and thanks to the application of machine learning, deep learning and big data analytics we will be able to design an ATM system that is smarter and safer by constantly analysing and learning from the ATM environment.
	U-space and urban air mobility	A digitally native traffic management system will ensure the safe and secure integration of drones in the airspace especially in urban areas, taking into account new and existing air vehicles and autonomous operations. One of the most challenging use cases from U-space will be to enable urban air mobility, which is expected to advance autonomous technologies in a number of areas.
	Virtualisation and cyber-secure data sharing	Service provision will be decoupled from the physical infrastructure, enabling air traffic and data service providers, irrespective of national borders, to plug in their operations where needed in a secure manner.
	Capacity-on-demand and dynamic airspace	Technology will enable the dynamic reconfiguration and the activation of cross-border capacity-on-demand services to maintain smooth traffic services at busy times.
	Civil/military interoperability and coordination	Dual-use technologies such as those for communications, navigation and surveillance, and other solutions that allow real-time exchange trajectory information will improve the predictability of military operations and overall network capacity.

In addition to scientific R&I, significant research is also required into regulatory issues:

- Ability of Member States to dynamically change responsibility for ATS in their airspace,
- Certification and approval of highly automated systems,
- Economic regulation of different elements of the value chain.

Importance of Architecture

The specific objectives place high importance of developing a service oriented architecture to develop and maintain consensus.

Many of the limitations of the current system have been caused by a lack of a defined architecture. Rather, bespoke national systems have been connected together using a range of bespoke interface standards specific to ATM. This has led to limited interoperability, high maintenance costs and significant difficulty in achieving widespread deployment of new systems (due to the high level of local adaptation required).

The required transition needs to be highly coordinated and based on commonly agreed service and infrastructure principles. The proposed architecture is the framework to achieve those agreements.

Once established, the architecture will allow different parts of the system to develop at different speeds depending on local needs whilst maintaining an overall coherence at network level. The wider implication of this is the ATM R&I would then need to be less coordinated and innovations would be developed within the common framework.

Importance of standards

As a highly regulated industry, ATM has many standards, at global level as annexes to ICAO's Chicago Convention³³ and at regional level – in Europe ATM standards and

³³ See: <https://www.icao.int/publications/pages/doc7300.aspx>

specifications are developed by EUROCAE, EUROCONTROL and the European Standardisation Organisation.

However, it is still possible to implement a change to an ATM system without a standard. In this case the ANSP prepares a detailed safety case for the regulator demonstrating that the proposed change is safe and interoperable. This route has enabled piecewise modernisation of the current fragmented system – in which the level of local adaptation can outweigh the benefits of standardisation.

Adoption of a common architecture reduces the need for local adaptation and increases the needs for standards. Many of the existing standards may need to be updated to suit the new architecture. Proposals are being developed within the architecture to separate key concerns leading to new forms of standards, for example:

- Operational services – The ATM services (separation, sequencing),
- Information services - The information services required to provide ATM services,
- Infrastructure requirements – The technical performance of the underlying infrastructure to provide the information services,
- Hardware requirements – Specifications of specific physical equipment (radars, radios etc).

A key output of the R&I will be the evidence required by the standards development organisations to develop and validate the required standards.

Economic impact

The European ATM Master Plan,³⁴ identified two rollout scenarios differentiated by the extent to which the ATM community joins forces and changes working methods to accelerate the R&I lifecycle:

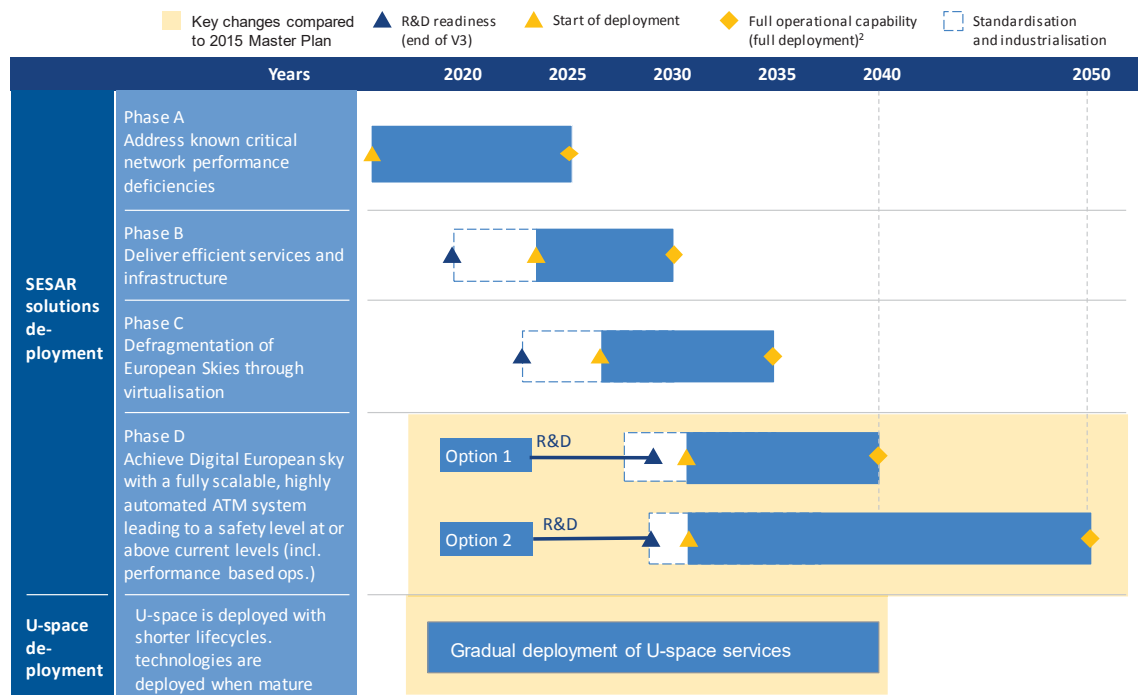

- Option 1: Full implementation of the SESAR vision by 2040 (requires strong partnership approach)
- Option 2: Full implementation of the SESAR vision by 2050

Figure 7 illustrates the roll-out of the SESAR Vision, supported by the existing SESAR programme, including the implementation of an optimised European airspace architecture and the ‘fast tracking’ of the deployment of U-space services during the next MFF.

The two options for the rollout of technology enabling the completion of phase D of the Master Plan (which related to the R&I required during the Horizon Europe timeframe) are shown; option 1 requires an earlier start of implementation and thus industry and stakeholders’ consensus and commitment.

³⁴ European ATM Master Plan, Edition 2020, SJU.

Figure 7: SESAR Roll Out Plan

Source: European ATM Master Plan Edition 2020, SJU, 2019.

The economic benefits are summarised in Table 3, where:

- All monetary figures are expressed in EUR billion.
- The table shows the cumulative results for the period 2019 to 2050 (both years included).
- Although Option 1 is fully deployed by 2040, the benefits continue to be accrued until 2050.

Table 3: Economic Value of SESAR Roll-out scenarios

	Option 1	Option 2	Delta
Level of investment	37	53	16
Direct benefits of the ATM value chain	510	490	20
Indirect benefits of additional GDP	170	160	10
Indirect benefits for passengers and EU citizens	760	730	30
Total benefits for Manned Aviation	1440	1380	60
Benefits of deploying U-space	350 to 400	250 to 300	Over 100
Total Benefits	1790 to 1840	1630 to 1680	Over 160

Source: SJU analysis of Business Cases developed for the European ATM Master Plan Updated Programme.

Achieving option 1 would make it possible to reap crucial benefits about a decade earlier and at a lower cost, thanks to cutting on transition costs and going straight to the performing solutions and organisation. This requires new ways of working:

- More agility: creating solutions through prototypes and demonstrations developed in smaller teams with shorter time frames; developing solutions by addressing service-related challenges without prejudging upfront what the optimal technical solution is; creating innovation labs to fast-track R&D, perform quick prototyping and incubate new ideas.
- Openness, in the form of increased collaboration between ‘traditional’ engineering domains and new entrants that are now likely to attract more capital.
- Coordination to reduce innovation cycles from about 30 years to about 5-10 years, focusing on disruptive innovation. To achieve this, the development and deployment of the integration of drones into the airspace, and in particular the development and implementation of U-space services, may be used as a ‘laboratory’ that can support faster life cycles in the manned aviation environment; in addition, ‘sandboxing’ between organisations may allow faster times to market.

A regulatory framework that will also be required to support innovation — through market take-up, incentives for early movers and focus on delivery of services, with an emphasis on what services should be provided and how, rather than on what technologies should be implemented.

This innovative approach would allow better connections and synchronisation between ground-based developments and the airborne industry, whose plans and expectations for the future are already known.

The need for SESAR

Figure 8 illustrates the historical evolution of air traffic delays in Europe, also referred to as en-route Air Traffic Flow Management delay. This is the delay accumulated due to the lack of capacity of portions of airspace dedicated to cruise phase of the flights (also referred to as en-route). When capacity is reached, all aircraft planned to enter that portion of airspace subsequently are delayed.

Figure 8: Evolution of en-route Air Traffic Flow Management delay in Europe.

Source: Authors analysis of PRR2018.

The three peaks in delay are worthy of note. In late 1990s significant delays led to two forms of intervention:

- The creation by EUROCONTROL of the Central Flow Management Unit (CFMU)³⁵ and successful implementation of key capacity enablers including RVSM³⁶ and B-RNAV.³⁷
- The development of the Single European Sky initiative, leading to the first package of legislation in 2004.

In the early 2000's delays were growing, and a similar delay crisis was predicted - but with limited confidence that technical solutions existed. This led to the creation of the SESAR programme. The crisis did not materialise due to fall in air traffic following the 2008 financial crisis.

In 2018 significant delays returned. Potential solutions from the current SESAR programme have been identified in the Airspace Architecture Study³⁸ to resolve the problem. The proposed integrated ATM partnership would have the objective of accelerating the development and deployment of the necessary solutions.

SESAR in the SES Context

The EU competence in Air Traffic Management, exercised through the Single European Sky, is designed to drive performance improvement at EU level through a range of measures including economic regulation³⁹ and network functions.⁴⁰ As the recent Court of Auditors report makes clear,⁴¹ the SES initiative is justified but not yet fully effective.

The Single European Sky (SES) was the Commission's response to the significant air transport delays that plagued the 1990s. The SES legislation promotes the development, modernisation, and harmonisation of Air Traffic Management (ATM) across Europe. Over the years, SES has developed into a performance-oriented system in which the service providers (or ANSPs) are incentivised to adopt new concepts and technologies (as well as new ways of managing the business) to achieve the SES High Level goals.

In 2006, the European Commission launched the SESAR programme, "technological pillar" of the Single European Sky: *"It aims to improve Air Traffic Management (ATM) performance by modernising and harmonising ATM systems through the definition, development, validation and deployment of innovative technological and operational ATM solutions"*.⁴²

Thus, the SESAR programme consists of definition of the strategic research and innovation agenda, R&I activities and deployment activities, all linked through the SESAR innovation lifecycle. The SESAR innovation lifecycle is central to the SES policy. SESAR is designed to mature and validate operational concepts and systems necessary for the modernisation of ATM. European airspace is amongst the busiest and most complex in the world. Traditionally Air Navigation Services have been provided by a patchwork of different national systems operated by national providers known as Air Navigation Service Providers (ANSPs).

The SESAR programme is defined as a continuous lifecycle that steers the R&I programme to effectively close performance gaps in the deployed system as illustrated in Figure 9.

³⁵ The Central Flow Management Unit (CFMU) provides Air Traffic Flow Management across Europe and is now a central part of the Network Manager, and changed the name to Network Manager Operations Centre (NMOC).

³⁶ Reduced Vertical Separation Minima (RVSM) allowed the vertical separation minima to be reduced from 2000 to 1000 ft in en-route airspace and provided a large capacity increase.

³⁷ Basic Area Navigation (B-RNAV) is a forerunner of Required Navigation Performance (RNP5) for en-route airspace and enabled a flight efficient and capacity benefit.

³⁸ A proposal for the future architecture of the European airspace, SJU, 2019.

³⁹ Commission Implementing Regulation (EU) 2019/317 of 11 February 2019 laying down a performance and charging scheme in the single European sky and repealing Implementing Regulations (EU) No 390/2013 and (EU) No 391/2013.

⁴⁰ Commission Implementing Regulation (EU) 2019/123 of 24 January 2019 laying down detailed rules for the implementation of air traffic management (ATM) network functions and repealing Commission Regulation (EU) No 677/2011.

⁴² Source: https://ec.europa.eu/transport/modes/air/sesar_en

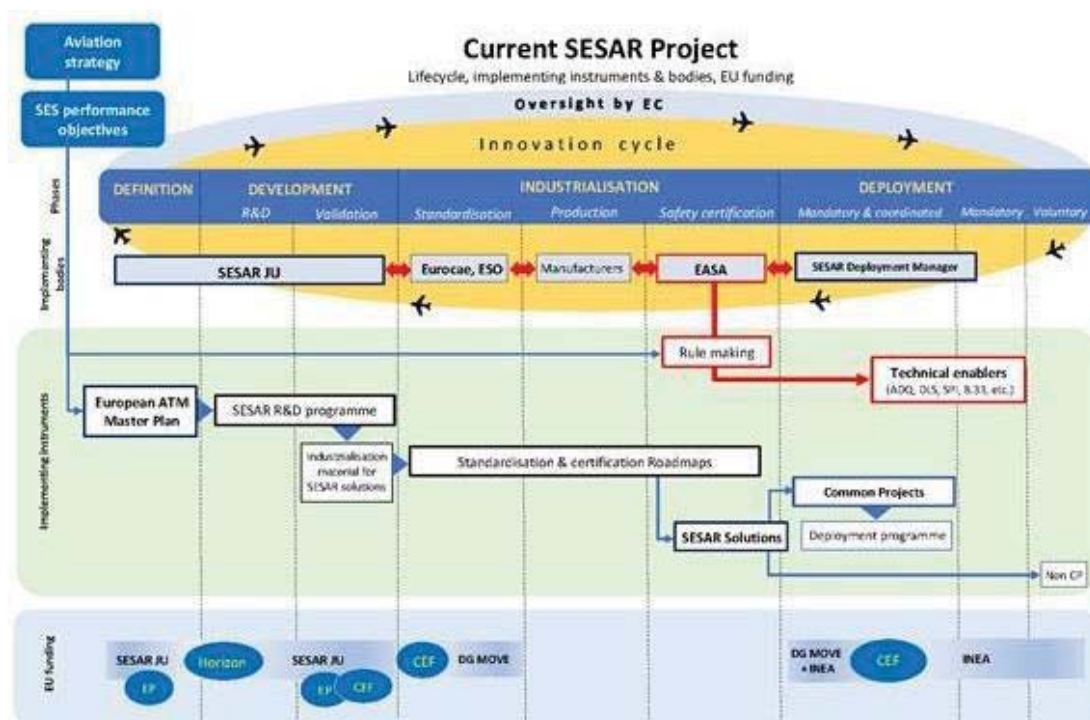

Figure 9: SESAR Innovation Lifecycle⁴³

Source: DG-MOVE.

Key issues for accelerating deployment in ATM are:

- Reducing the implementation risks for both equipment supplier and ANSPs by ensuring that regulators and standardisation bodies have the current evidence to support operational approval and standards development. This is referred to as closing the industrialisation gap⁴⁴ and should be an objective of the future integrated ATM partnership.
- Ensuring a common and agreed evolution of systems hence reducing the commercial risk in developing products – in Europe this is achieved through the ATM Master Plan.
- Enabling synchronised deployment to reduce the time between system deployment and accruing benefits by ensuring that national ANSPs invest in a coherent manner – this is an objective of the SESAR deployment phase and common project legislation.⁴⁵

R&I Prior to SESAR

Prior to SESAR, significant R&D was being undertaken in Air Traffic Management:

- EUROCONTROL spent about €150-200m a year on R&D;

⁴³ Source: DG-MOVE, European Commission

⁴⁴ Interim evaluation of the SESAR Joint Undertaking (2014-2016) operating under Horizon 2020, Experts Group Report.

⁴⁵ Commission Implementing Regulation (EU) No 716/2014 of 27 June 2014 on the establishment of the Pilot Common Project supporting the implementation of the European ATM Master Plan Text with EEA relevance.

- The Commission funding for ATM under the Fifth Framework Programme amounted to €20.8m between 1998 and 2002, and by around €100m over the 2002-2006 period;
- The European Investment Bank also contributed €390m to support ATM in Europe between 1999 and 2003.⁴⁶

A 2006 review of existing R&D identified 58 initiatives; including:⁴⁷

- FP6 funded 44 ATM⁴⁸ related research projects. The topics covered wide range, and some, became central to the SESAR Development Phase work programme, for example:
 - EPISODE 3 set foundation for the SESAR operational concept and performance framework.
 - SWIM-SUIT project came up with the precursors of the current SWIM solutions.
 - The ART project laid groundwork for SESAR remote tower solutions.
 - The EMMA projects pioneered A-SMGCS solutions.
- EUROCONTROL research included the PHARE programme which included research on 4D trajectory management and formed the basis of the concept developed within the SESAR Definition Phase. PHARE included strong input from the national programmes including Netherlands (NLR), Germany (DLR), France (DSNA) and the UK (NATS, DERA).
- National Programmes which fed into the procurement plans of ANSPs. In particular, LFV in Sweden had a strong national programme.

Despite the reasonable level of research, the programmes overlapped with each other and the results were fragmented leading to low value for money. The combined research effort was leading to competing rather than a common view of the future of ATM.

A key objective of SESAR was to coordinate all European ATM research towards a common goal, which was mandated by the SESAR Joint Undertaking regulation.⁴⁹

The SESAR Joint Undertaking⁵⁰

Scope and objectives

The SESAR Joint Undertaking was initially established in 2007 with the objectives and tasks defined in Table 4.

Table 4: Objectives and tasks of the SESAR Joint Undertaking

Objectives and tasks of the SESAR Joint Undertaking

The aim of the Joint Undertaking shall be to ensure the modernisation of the European air traffic management system by coordinating and concentrating all relevant research and development efforts in the Community. It shall be responsible for the execution of the European ATM Master Plan and in particular for carrying out the following tasks:

- organising and coordinating the activities of the development phase of the SESAR project, in accordance with the

⁴⁶ SEAME CBA and Governance Study, Steer Davies Gleave, 2005.

⁴⁷ SESAR Consortium DLT-0507-221-00-02, 2006.

⁴⁸ The R&I tended to be conducted by research organisations and ANSPs, with limited involvement from airspace users and airport operators. Total ATM related research received €167m in funding (with the total budget of €289m).

⁴⁹ Council Regulation (EC) No 219/2007 of 27 February 2007 on the establishment of a Joint Undertaking to develop the new generation European air traffic management system (SESAR)

⁵⁰ Interim Evaluation of the SESAR Joint Undertaking (2014-2016) operating under Horizon 2020, Experts Group Report.

Objectives and tasks of the SESAR Joint Undertaking

European ATM Master Plan, resulting from the definition phase of the project managed by EUOCONTROL, by combining and managing under a single structure public and private sector funding,

- ensuring the necessary funding for the activities of the development phase of the SESAR project in accordance with the European ATM Master Plan,
- ensuring the involvement of the stakeholders of the air traffic management sector in Europe, in particular: air navigation service providers, airspace users, professional staff associations, airports, and manufacturing industry; as well as the relevant scientific institutions or the relevant scientific community,
- organising the technical work of research and development, validation and study, to be carried out under its authority while avoiding fragmentation of such activities,
- ensuring the supervision of activities related to the development of common products duly identified in the European ATM Master Plan and if necessary, to organise specific invitations to tender.

Source: Council Regulation (EC) No 219/2007 of 27 February 2007 on the establishment of a Joint Undertaking to develop the new generation European air traffic management system (SESAR).

At the core of the activities of the SESAR Joint Undertaking is the European ATM Master Plan which acts as the strategic research and innovation agenda for the partnership.

The first version of the European ATM Master Plan was developed prior to the establishment of the SESAR Joint Undertaking and endorsed by the European Council in 2009. Since then, the European ATM Master Plan has been regularly updated by the SESAR Joint Undertaking following widespread stakeholder consultation. Each version requires approval of Member States through a positive opinion of the Single Sky Committee.⁵¹

Table 25 defines the main changes in each subsequent version of the European ATM Master Plan.

Table 5: Versions of the European ATM Master Plan

Edition	Additional Changes	MS State Endorsement
2009	Initial version created by the SESAR Definition Phase	Council Decision ⁵²
2012 ⁵³	Increase the ATM community's awareness and focusing efforts on a manageable set of essential operational changes. Prepare for SESAR deployment phase, developing clear stakeholder roadmaps which provide a temporal view of the ATM. Promote and ensure interoperability at global level, in particular with the US ATM Modernisation programme, NextGen and ICAO. Promote synchronisation of ATM R&I and Deployment Programmes to ensure global interoperability.	SSC Opinion
2015 ⁵⁴	Introduced a vision for the future European ATM system, including Common Support Services and cybersecurity. Explicitly introduces drones and rotorcraft as airspace users. Incorporates the results of more comprehensive military involvement through the European Defence Agency (EDA).	SSC Opinion
2020	Addresses new challenges: tackling the unprecedented increase in traffic demand from both manned, and unmanned aviation, enabling the emergence of new business models, while supporting the sustainability of	SSC Opinion

SESAR Joint Undertaking Membership

SESAR Joint Undertaking membership includes the main stakeholders of the European ATM industry including air navigation service providers, airports, equipment manufacturers and R&I laboratories. There are currently 19 SESAR Joint Undertaking members composed of 37 individual companies (see Table 8). In addition, EUROCONTROL is a founding Member.

Table 8: Members of the SESAR Joint Undertaking

Member	Beneficiary	Sector	Country

Source: Interim Evaluation of the SESAR Joint Undertaking (2014-2016), Experts Group Report.

Approximately 80% of SESAR R&I is performed by the members following “closed calls”. The members’ supply chains support their contributions as third link parties or as subcontractors to the members.

SESAR Joint Undertaking membership does not directly include Universities and SMEs. However, the remaining 20% of R&I activities is performed by a range of academia and SMEs following open calls – mostly of Exploratory Research. In total, there have been 268 individual participants in the SESAR2020 programme (both open and closed calls). The private sector dominates with almost 70%, with the 18% of participation from Higher education sector, and 9% coming from Research organisations, as depicted in Figure 11.

Achievements of the SESAR Joint Undertaking

The focus of the current R&I programme is to develop and validate advanced solutions and concepts for the future air traffic management system in line with the European ATM Master Plan. Each solution represents a change in the way air traffic management is performed, and is supported by:

- A business case,
- A safety case,
- A performance case,
- A human performance case,
- A specification or similar material to support standardisation.

The SESAR Solutions Catalogue⁵⁹ defines 63 such solutions that have reached a sufficient maturity for deployment. EUROCAE and EUROCONTROL have developed over 50 standards to support deployment of SESAR solutions.⁶⁰

For **scientific and technological analysis** of the current partnership, it is important to bear in mind the type of partners involved and the field of partnership, which is ATM. Scientific publications can be

⁵⁹ SESAR Solutions Catalogue 2019 Third edition, SJU, 2019.

⁶⁰ Source: https://ec.europa.eu/transport/sites/transport/files/ec-716-2014_article4b_standardisatregulatroadmap.pdf

expected predominantly from the academic partners and from research organisations, but much less so from industry partners.

Based on the data available through DG RTD, 24 of the SESAR projects produced 32 publications in the field of ‘Smart, green and integrated transport’ (see Table 9).

Table 9: Number and share of publications by year.

The search of SCOPUS database produced 93 scientific papers in the period 2012-2019 (87 in the period 2014-2019) that listed as the source of funding SESAR Joint Undertaking. A number of these papers have been presented at the conferences (which are indexed in SCOPUS), as in some of the disciplines that are participating in the ATM, conferences are of more importance than the publications in journals.

The three main, peer-reviewed conferences in the ATM are:

1. The ATM Seminar, organised biannually, jointly by the Federal Aviation Administration and EUROCONTROL, aimed at established researchers (www.atmseminarus.org);
2. International Conference on Research in Air Transportation (ICRAT), organised biannually, jointly by the Federal Aviation Administration and EUROCONTROL, aimed at young researchers (www.icrat.org);
3. SESAR Innovation Days, organised by the SESAR Joint Undertaking, every year (<https://www.sesarju.eu/sesarinnovationdays>).

Conference proceedings are publicly available on the conference websites, and are indexed in the SCOPUS database.⁶¹ The last three editions of ATM Seminar (2013-2017, as listed in SCOPUS) include 217 peer-reviewed papers. The ATM Seminar confers awards for best papers in each session and best conference paper. In the last two editions of the ATM Seminar, about half of the awards were won by European researchers, a significant number working on SESAR Joint Undertaking funded projects.⁶²

The SESAR Innovation Days conference is open to any research in the field of ATM, and is aimed at reviewing and showcasing the research performed in the SESAR Joint Undertaking. There have been eight editions of the conference so far, and the number of accepted papers has been growing.

In summary, the research produced under the current partnership is of high scientific value, when assessed across the indicators that are important in the field – participation and awards received at the main conferences.

The **technological achievements** of the partnership are presented in terms of patent analysis and the technological solutions developed and implemented.

Patents can be expected from industry partners since they have a genuine interest in protecting their innovation. However, due to competition, business practices and the pre-competitive nature of collaborative R&I projects at EU-level, etc. most industrial partners in the field of ATM are not likely to apply for IPR. Therefore, the numbers of IPs recorded in the DG RTD database are of little use to describe properly the technological achievements of the partnership. IPRs can be found as outputs from three projects: two applied for a patent and one for a trademark.

The more important technological achievement of the partnership can be found in the catalogue of mature⁶³ ATM solutions produced by the partnership: SESAR Solutions Catalogue 2019,⁶⁴ containing 63 mature solutions and 79 solutions being developed. These solutions have been tested in over 200 validation exercises, at over 50 test beds across Europe.

Figure 14 displays a sample of locations deploying the SESAR solutions. The blue markers denote the airports deploying SESAR Solutions that are mandated through the EU's Pilot Common Project⁶⁵, while the green markers point to the sample of locations where local SESAR deployments⁶⁶ are taking place.

⁶¹ It takes a while for the proceedings to be indexed in SCOPUS, which is why the last ATM Seminar from June of 2019 and several SESAR Innovation Days proceedings are not yet available.

⁶² Source: www.atmseminarus.org

⁶³ Mature from the R&I point of view, which is to say passing TRL 6.

⁶⁴ SESAR Solutions Catalogue, SJU, 2019.

⁶⁵ Commission Implementing Regulation (EU) No 716/2014 of 27 June 2014 on the establishment of the Pilot Common Project supporting the implementation of the European Air Traffic Management Master Plan Text with EEA relevance.

⁶⁶ The detailed implementation data is available at: <https://www.atmmasterplan.eu/deployment>

Figure 14: Locations where SESAR Joint Undertaking solutions are being deployed

Source: SESAR Solutions Catalogue 2019.

The current deployment programme encompasses 349 projects with total costs of €2.9 billion with €1.2 billion co-funding the Connecting Europe Facility.

In summary, the current partnership (and as such the ATM R&I in Europe) produces high-quality scientific knowledge and a number of technological achievements are available and are being deployed, not only in Europe.

Outcomes and (expected) impacts

Since its inception in 2008, the SESAR Joint Undertaking has successfully coordinated European ATM R&I. The success of SESAR is best illustrated by the European ATM Master Plan, culminating in the 2015 edition,⁶⁷ and SESAR Solutions Catalogue.⁶⁸ To date 63 ATM solutions have been developed.

In addition, SESAR is strong brand demonstrating EU leadership in ATM in a competitive global landscape.⁶⁹ Indeed, the SESAR Joint Undertaking played a strong role in the development of global plans at ICAO level and in maintaining international interoperability of ATM systems through coordination with the FAA (Federal Aviation Authority) and other similar initiatives.⁷⁰

⁶⁹ Interim Evaluation of the SESAR Joint Undertaking (2014-2016) operating under Horizon 2020, Experts Group Report.

⁷⁰ Section 2.5 of SESAR Joint Undertaking Single Programming Document 2019-2021, SJU, 2019.

The SESAR Joint Undertaking has also supported the European Commission's development of aviation and ATM policy through key studies performed at the request of DG-MOVE, including datalink communications,⁷¹ U-space⁷² and the recent Airspace Architecture Study.⁷³

The SESAR Joint Undertaking results have therefore contributed to improvement of ATM both in the EU and globally. The key strengths of the SESAR Joint Undertaking are:

- Strong global brand supporting EU leadership,
- SESAR solutions demonstrably improving ATM performance,
- Integrated R&I platform including users, providers, suppliers, staff and regulators.

Identified needs for action

Previous assessments stress the importance of *SESAR and the SESAR Joint Undertaking as key enablers for the implementation of the wider SES policy*⁷⁴. However, two key weaknesses were found:

- Limited exploitation of advanced external R&I and internal exploratory research in the core ("closed call") programme. This illustrates a potential issue in the limited membership of the SESAR Joint Undertaking not enabling the beneficiaries of Exploratory Research to continue on the topic in the core programme.
- Limited progress on key enablers where there is limited industry consensus (for example, next generation datalinks and flight data processing) potentially highlighting the need for greater emphasis on transformational technologies.

In 2018, the SESAR Joint Undertaking performed a study on behalf of the European Parliament and European Commission to develop a proposal for a Future Airspace Architecture. Whilst the proposal is largely based on the current European ATM Masterplan, it also represents a step change in requiring both more transformational technologies and faster pull through from scientific research of digital enablers to support enhanced automation.

The European Court of Auditors has considered both SES⁷⁵ and SESAR Deployment,⁷⁶ other parts of the SESAR innovation lifecycle. The former provided three recommendations relevant to the SESAR Joint Undertaking and to the future ATM research and development activities:

- Review the EU's support structure to ATM R&I in light of its objectives – including the need to justify continued support and whether a temporary structure is appropriate.
- Reinforce the accountability of the SESAR Joint Undertaking – by defining clear milestones and regular reports on progress with the implementation of the European ATM Master Plan.
- Prioritise EU support to R&I solutions that promote defragmentation and a competitive environment.

Delivering the Single European Sky and ensuring ATMs role in a sustainable aviation sector requires a much greater transformation than has hitherto been achieved. The level of transformation is discussed in Annex F.

Aviation contribution to Sustainable Development Goals

“The 2030 Agenda for Sustainable Development, adopted by all United Nations Member States in 2015, provides a shared blueprint for peace and prosperity for people and the planet, now and into the future. At its heart are the 17 Sustainable Development Goals (SDGs), which are an urgent call for action by all countries - developed and developing - in a global partnership.”⁷⁷

Aviation as a provider of transport and mobility is able to support a number of SDGs. ATM as an enabler of efficient transport contribute to multiple Sustainable Development Goals:

- SDG 9 (Industry, Innovation and Infrastructure)
- SDG 11 (Sustainable Cities and Communities)
- SDG 13 (Climate Action)

Indirect positive impact is expected for example in:

- SDG 3 (Good health and well-being)
- SDG 8 (Decent work and economic growth)
- SDG 12 (Responsible production and consumption)⁷⁸

The following table has been developed from a report developed by Air Transport Action Group (ATAG) to illustrate how aviation can contribute to 11 SDGs.⁷⁹

Table 11: How aviation can contribute to 11 Sustainable Development Goals

SDG	How Aviation can support		
	Direct	Indirect	Induced
1. No poverty	Creating jobs in air transport connected places	Continuity of remittances is supported by the maintenance of family and cultural ties is aided by air transport links.	
2. Zero hunger		The World Food Programme (WFP), in partnership with the UN Humanitarian Air Service, is tasked with getting food to those in the midst of war, civil conflict and natural disasters. Because many of these zones are inaccessible by road, air transport is the only option.	
3. Good health and well-being		The industry, too, has a vital role to play in responding to disaster. In 2010, Airlink was established to help coordinate responses to emergencies by the air transport industry.	Aviation also has a crucial role to play in pandemic response. When a viral outbreak occurs, it is vital that the air transport sector acts quickly to work with governments and international institutions to ensure that the virus does not travel further.

⁷⁷ Sustainable development goals knowledge platform. Available at: <https://sustainabledevelopment.un.org/sdgs>

⁷⁸ European Commission (2019) Orientations towards the first Strategic Plan implementing the research and innovation framework programme Horizon Europe. Co-Design via web open consultation.

⁷⁹ Aviation Benefits Beyond Borders, ATAG, October 2018.

SDG	How Aviation can support		
	Direct	Indirect	Induced
4. Quality education		Ensuring inclusive and equitable quality education and promoting lifelong learning opportunities for many means travelling to another country, sometimes in another region of the globe. For students from developing countries, the opportunity to travel to established universities for higher education is invaluable.	Air transport connectivity make these ambitions far more likely to be realised.
7. Affordable and clean energy		Airport planning and design also takes into consideration environmental aspects to maximise efficiency with the minimal possible impact on the environment.	
8. Decent work and economic growth	Creating jobs that directly serve passengers at airlines, airports and air navigation service providers (ASNPs)	Employment and activities of suppliers to the air transport industry	Spending of those directly or indirectly employed in the air transport sector supports additional jobs in other industries
9. Industry, innovation and infrastructure	Since the dawn of air travel, aviation has been at the forefront of technological innovation, researching and developing disruptive, ground-breaking technology with each new generation of aircraft or each new control technique.		Connectivity contributes to improved productivity by encouraging investment and innovation, improving business operations and efficiency.
10. Reduced inequalities	The greatest increase in propensity to travel is in developing economies, reducing geographical inequalities.		In developed economies the connectivity to rural areas is increasing, making it more accessible to everyone.
11. Sustainable cities and communities	New technology will enable some remote and seasonal airports to remain open and viable improving sustainability.	Smaller airports within a network generate traffic that ensures the sustainability of larger airports, resulting in improved load factors and optimal aircraft utilisation by airlines.	
12. Responsible consumption and production	Once an aircraft reaches the end of its service life, it can be recycled to ensure safe disposal and to take advantage of the many high-quality components and materials of which it is made. The idea is to move this idea into the ATM industry too by recycling and not having an excess of radars. Virtual centres allow to have a responsible use of air traffic services.	It is the role of countries to ensure that improvements in ATM infrastructure are properly financed. As there are long lead times for procuring new equipment, such as air traffic control centres and the latest surveillance equipment, ATM investment needs long-term planning.	

SDG	How Aviation can support		
	Direct	Indirect	Induced
13. Climate action	In 2008 industry leaders announced a climate action plan based on three global goals, which the entire sector has committed to: 1. Achieve a 1.5% average annual fuel efficiency improvement from 2009 to 2020 (already being surpassed, average 2.1% per year). 2. Stabilise net CO2 emissions at 2020 levels through carbon-neutral growth. 3. Reduce net emissions to 50% of what they were in 2005 by 2050.	While the aviation industry is prioritising fuel efficiency to try and reduce its climate change impact, there are a number of ways in which a changing climate could impact air transport operations.	
17. Partnerships for the goals	For the potential of new navigational technology to be realised, the industry needs the engagement and cooperation of governments and international institutions. Airspace is governed by sovereign states, meaning that any reform needs governmental buy-in. But aviation transcends national boundaries.	Encouraging progress has been made on the first three pillars of the industry's environmental strategy. However, to achieve the goal of carbon-neutral growth from 2020 other measures need to be taken.

PART 1 - COMMON FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1. BACKGROUND AND CONTEXT TO EUROPEAN PARTNERSHIPS IN HORIZON EUROPE AND FOCUS OF THE IMPACT ASSESSMENT– WHAT IS DECIDED

1.1. Focus and objectives of the impact assessment

This impact assessment accompanies the Commission proposal for Institutionalised European Partnerships to be funded under Horizon Europe, the 2021-2027 Framework Programme for EU Research and Innovation (R&I).¹ It sets out to **help decide in a coordinated manner the right form of implementation for specific candidate initiatives** based on a common approach and methodology for individual assessments². It also provides a **horizontal perspective on the portfolio of candidate European Partnerships** to identify further efficiency and coherence gains for more impact.

European Partnerships are initiatives where the Union, together with private and/or public partners (such as industry, public bodies or foundations) commit to support jointly the development and implementation of an integrated programme of R&I activities. The rationale for establishing such initiatives is to achieve the objectives of Horizon Europe more effectively than what can be attained by other activities of the programme.³

Based on the Horizon Europe Regulation, European Partnerships may be set up using **three different forms**: “Co-funded”, “Co-programmed” and “Institutionalised”. The setting up of **Institutionalised Partnerships** involves new EU legislation and the establishment of dedicated implementing structures based on Article 185 or 187 of the Treaty on the Functioning of the EU (TFEU). This requires an impact assessment to be performed.

The Horizon Europe Regulation defines **eight priority areas**, scoping the domains in which Institutionalised Partnerships could be proposed⁴. Across these priority areas, **13 initiatives** have been identified as **suitable candidate initiatives** for Institutionalised Partnerships due to their objectives and scope. This impact assessment aims to identify whether 12 of these initiatives⁵ need to be implemented through this arrangement, and would not carry out their activities equally well with traditional calls of Horizon Europe or other lighter forms of European Partnerships under Horizon Europe. This means assessing whether each of these initiatives meets the necessity test set in the **selection criteria** for European Partnerships in the Horizon Europe Regulation, Annex III.

This assessment is done **without any budgetary considerations**, as the overall budget of the Multiannual Financial Framework of the EU – and hence of Horizon Europe – for the next financing period is not known at this stage.⁶

¹ Horizon Europe Regulation (common understanding), <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

² Based on the European Commission Better Regulation framework (SWD (2017) 350) and supported by an external study coordinated by Technopolis Group (to be published in 2020).

³ For further details on these points, see below Section 1.2.2.

⁴ Set out in the Annex Va of the Horizon Europe Regulation (common understanding). <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

⁵ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47).

⁶ EU budget commitments to the European Partnership candidates can only be discussed and decided following the political agreement on the overall Multiannual Financial Framework and Horizon Europe budgetary envelopes. The level of EU contribution for individual partnerships should be determined once there are agreed objectives, and clear commitments

1.2. The political and legal context

1.2.1. Shift in EU priorities and Horizon Europe framework

European priorities have evolved in the last decades, and reflect the social, economic, and environmental challenges for the EU in the face of global developments. In her Political Guidelines for the new European Commission 2019 – 2024⁷, the Commission President put forward six overarching priorities, which reach well beyond 2024 in scope⁸. Together with the Sustainable Development Goals (SDGs), these priorities will shape future EU policy responses to the challenges Europe faces, and thus also give direction to EU research and innovation.

As part of the Multi-annual Financial Framework (MFF) 2021-27 the new EU Framework Programme for Research and Innovation **Horizon Europe will play a pivotal role for Europe to lead the social, economic, and environmental transitions needed to achieve these European policy priorities**. It will be more impact driven with a strong focus on delivering European added value, but also be more effective and efficient in its implementation.⁹ Horizon Europe finds its rationale in the daunting challenges that the EU is facing, which call for “*a radical new approach to developing and deploying new technologies and innovative solutions for citizens and the planet on a scale and at a speed never achieved before, and to adapting our policy and economic framework to turn global threats into new opportunities for our society and economy, citizens and businesses.*” While Horizon Europe continues the efforts of strengthening the scientific and technological bases of the Union and foster competitiveness, a more strategic and impact-based approach to EU R&I investment is taken. Consequently, the **objectives of Horizon Europe** highlight the need to *deliver on the Union strategic priorities and contribute to the realisation of EU objectives and policies, contribute to tackling global challenges, including the Sustainable Development Goals by following the principles of the Agenda 2030 and the Paris Agreement.*¹⁰

In this context, **at least 35 % of the expenditure from actions under the Horizon Europe Programme will have to contribute to climate action**. Furthermore, a **Strategic Plan** is co-designed with stakeholders to identify **key strategic orientations for R&I support** for 2021-2024 in line with the EU priorities. In the Orientations towards the first Strategic Plan for Horizon Europe, the need to strategically prioritise and “*direct a substantial part of the funds towards the areas where we believe they will matter the most*” is emphasised. The Orientations specify, that actions under Pillar II of Horizon Europe “Global Challenges and European Industrial Competitiveness” will target only selected themes of especially high impact that significantly contribute to delivering on the political priorities of the Union. Most of the candidate European Partnerships fall under this Pillar.

from partners. Importantly, there is a ceiling to the partnership budgets in Pillar II of Horizon Europe (the legal proposal specifies that *the majority of the budget in pillar II shall be allocated to actions outside of European Partnerships*).

⁷ https://ec.europa.eu/info/strategy/priorities-2019-2024_en

⁸ 1.A European Green Deal; An economy that works for people; A Europe fit for the Digital Age; Promoting our European way of life; A Stronger Europe in the World; and 6.A New push for European Democracy

⁹ EC (2018) *A Modern Budget for a Union that Protects, Empowers and Defends. The Multiannual Financial Framework for 2021-2027*. Communication from the Commission to the European Parliament, the European Council, the Council, the European Economic and Social Committee and the Committee of the Regions, COM(2018) 321 final

¹⁰ Article 3, Common understanding regarding the proposal for Horizon Europe Framework Programme.

1.2.2. Key evolutions in the approach to partnerships in Horizon Europe

Since their start in 1984, the successive set of Framework Programmes uses a variety of instruments and approaches to support R&I activities, address global challenges and industrial competitiveness. Collaborative, competition-based and excellence-driven R&I projects funded through Work Programmes are the most traditional and long-standing approach for implementation. Since 2002, available tools also include **partnerships**, whereby the Union together with private and/or public partners commit to jointly support the development and implementation of a R&I programme. These were introduced as part of creating the European Research Area (ERA) to align national strategies and overcome fragmentation of research effort towards an increased scientific, managerial and financial integration of European research and innovation. Interoperable and integrated national research systems would allow for better flows of knowledge, technology and people. Since then, the core activities of the partnerships consist of building critical mass mainly through collaborative projects, jointly developing visions, and setting strategic agendas.

As analysed in the **interim evaluation of Horizon 2020**¹¹, a considerable repertoire of partnership initiatives has been introduced over time, with eight forms of implementation¹² and close to 120 partnership initiatives running under Horizon 2020 - without clear exit strategies and concerns about their degree of coherence, openness and transparency. Even if it is recognised that these initiatives allow for setting long-term agendas, structuring R&I cooperation between otherwise dispersed actors, and leveraging additional investments, the evaluation points to the complexity generated by the proliferation of instruments and initiatives, and their insufficient contribution to policies at EU and national level.

Box 1 Key lessons from the interim evaluation of Horizon 2020 and R&I partnerships

- The **Horizon 2020 Interim Evaluation** concludes that the overall partnership landscape has become overly complex and fragmented. It identifies the need for rationalisation, to improve their openness and transparency, and link them with future EU R&I missions and strategic priorities.

- The **Article 185 evaluation** finds that these public-public partnerships have scientific quality, global visibility and networking/structuring effects but should, in the future, focus more on the achievement of policy impacts. From a systemic point of view, it found that the EU public-to-public cooperation (P2P) landscape has become crowded, with insufficient coherence.

- The **Article 187 evaluation** points out that Public-Private Partnership (PPP) activities need to be brought more in line with EU, national and regional policies, and calls for a revision of the Key Performance Indicators. As regards the **contractual PPPs (cPPPs)** their reviews identified challenges of coherence among cPPPs and the need to develop collaborations and synergies with

Over 80% of respondents to the Open Public Consultation (OPC) indicated that a significant contribution by future European Partnerships is 'fully needed' to achieve climate-related goals, to develop and effectively deploy technology, and for EU global competitiveness in specific sectors/domains. Views converged across all categories of respondents, including citizens, industry and academia.

¹¹ Interim evaluation of Horizon 2020, Commission Staff Working Document, SWD(2017)221 and 222 Interim evaluation of the Joint Undertakings operating under Horizon 2020 (Commission Staff Working Document, SWD(2017) 339); Evaluation of the Participation of the EU in research and development programmes undertaken by several Member States based on Article 185 of the TFEU, Commission Staff Working Document, SWD (2017)340

¹² E.g. initiatives based on Article 187 (Joint Technology Initiatives), Article 185 TFEU, Contractual Public-Private Partnerships (cPPPs), Knowledge & Innovation Communities of the European Institute of Innovation & Technology (EIT-KICs), ERA-NETs, European Joint Programmes, Joint Programming Initiatives.

The impact assessment of Horizon Europe identifies therefore the need to **rationalise the EU R&I funding landscape**, in particular with respect to partnerships, as well as to **re-orient partnerships towards more impact** and delivery on EU priorities. To address these concerns and to realise the higher ambitions for European investments, Horizon Europe puts forward **a major simplification and reform for the Commission’s policy on R&I partnerships**¹³. Reflecting its systemic nature which aims to contribute to EU-wide ‘transformations’ towards the sustainability objectives, Horizon Europe indeed intends to make a more effective use of these partnerships with a **more strategic, coherent and impact-driven approach**. Key related changes that apply to all forms of European Partnerships encapsulated in the Horizon Europe Regulation are summarised in the Box

Box 2 Key features of the revised policy approach to R&I partnerships under Horizon Europe based on its impact assessment

- ✓ **Simpler architecture & toolbox** by streamlining eight partnership instruments into 3 implementation forms (Co-Funded, Co-Programmed, Institutionalised), under the umbrella ‘European Partnerships’
- ✓ **More systematic and transparent approach** to selecting, implementing, monitoring, evaluating and phasing out all forms of partnerships (**criteria** for European Partnerships):
 - The selection of Partnerships is embedded in the strategic planning of Horizon Europe, thereby ensuring coherence with the EU priorities. The selection criteria require that partnerships are established with stronger ex-ante commitment and higher ambition.
 - The implementation criteria stipulate that initiatives adopt a systemic approach in achieving impacts, including broad engagement of stakeholders in agenda-setting and synergies with other relevant initiatives to promote the take-up of R&I results.
 - A harmonised monitoring & evaluation system will be implemented, and ensures that progress is analysed in the wider context of achieving Horizon Europe objectives and EU priorities.
 - All partnerships need to develop an exit strategy from Framework Programme funding. This new approach is underpinned by principles of openness, coherence and EU added value.
- ✓ **Reinforced impact orientation:**
 - Partnerships are established only if there is evidence they support achieving EU policy objectives more effectively than other Horizon Europe actions, by demonstrating a clear vision and targets (**directionality**) and corresponding long-term commitments from partners (**additionality**).
 - European Partnerships are expected to provide mechanisms – based on a concrete roadmap - to join up R&I efforts between a broad range of actors towards the development and uptake of innovative solutions in line with EU priorities, serving the economy and society, as well as scientific progress.
 - They are expected to develop close synergies with national and regional initiatives, acting as dynamic change agents, strengthening linkages within their respective ecosystems and along the value chains, as well as pooling resources and efforts towards the common EU objectives.

below.

Under Horizon Europe, a ‘European Partnership’¹⁴ is defined as *“an initiative where the Union, prepared with early involvement of Member States and/or Associated Countries, together with private and/or public partners (such as industry, universities, research organisations, bodies with a public service mission at local, regional, national or international level or civil society organisations including foundations and NGOs), commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”*

The Regulation further specifies that European Partnerships shall adhere to the *“principles of Union added value, transparency, openness, impact within and for Europe, strong leverage effect on sufficient scale, long-term commitments of all the involved parties, flexibility in implementation, coherence, coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships*

¹³ Impact assessment of Horizon Europe, Commission Staff Working Document, SWD(2018)307.

¹⁴ Article 8 and Annex III of the Horizon Europe Regulation (common understanding)

and missions.”

1.3. Why should the EU act

1.3.1. Legal basis

Proposals for Institutionalised European Partnerships are based on:

- 1) Article 185 TFEU which allows the Union to make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; or
- 2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes.¹⁵

1.3.2. Subsidiarity

The EU should act only in areas where there is demonstrable advantage that the action at EU level is more effective than action taken at national, regional or local level. Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the EU can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States’ freedom to act in the same areas. The candidate initiatives focus on areas where there is a demonstrable added value in acting at the EU level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national activities in the same area. Overall European Partnerships find their **rationale in addressing a set of systemic failures**¹⁶:

- Their primary function is to create a platform for a strengthened **collaboration** and knowledge exchange between various actors in the European R&I system and an enhanced **coordination** of strategic research agendas and/or R&I funding programmes. They aim to address **transformational failures** to better align agendas and policies of public and private funders, pool available resources, create critical mass, avoid unnecessary duplication of efforts, and leverage sufficiently large investments where needed but which are not achievable by single countries.
- The concentration of efforts and pooling of knowledge on common priorities to solve multi-faceted societal and economic challenges is at the core of these initiatives. Specifically, enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems are among the key objectives of these instruments. In the light of Horizon Europe, the aim is to **drive system transitions and transformations towards EU priorities**.
- Especially in fast-growing technologies and sectors such as ICT, there is a need to **react to emerging opportunities** and address systemic failures such as a shortage in skills or critical mass or cross-sectoral cooperation along the value chains that would hamper attainment of future European leadership and/or strategic autonomy.
- They also aim to address **market failures** predominantly to enhancing industry

¹⁵ Both Articles are under Title XIX of the TFEU - Research and Technological Development and Space.

¹⁶ The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide qualitative and quantitative evidence on these points. Sections 1 and 2 of each impact assessment on candidate European Partnerships include more detail on the necessity to act at EU level in specific thematic areas.

investments due to the sharing of risks.

2. THE CANDIDATE EUROPEAN PARTNERSHIPS – WHAT NEEDS TO BE DECIDED

2.1. Portfolio of candidates for Institutionalised European Partnerships

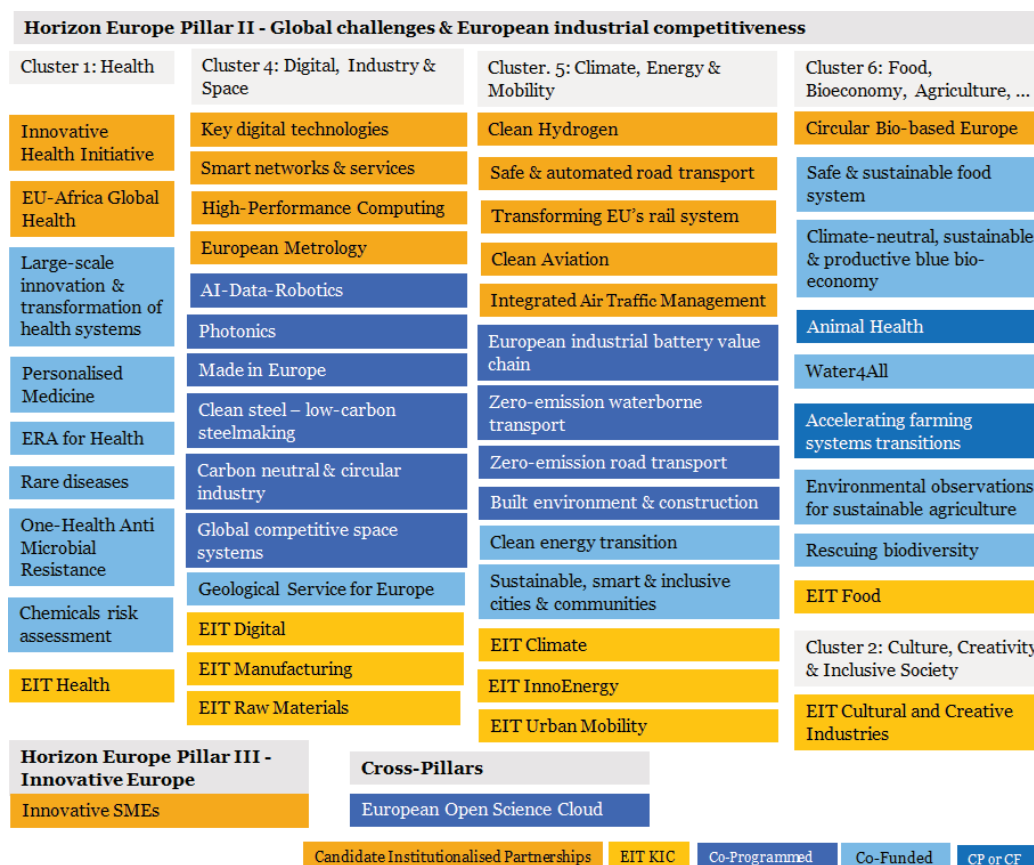

The new approach for more objective-driven and impactful European Partnerships is reflected in the way candidate Partnerships have been identified. It involved a co-design exercise aiming to better align these initiatives with societal needs and policy priorities, while broadening the range of actors involved. Taking into account the 8 areas for Institutionalised European Partnerships set out in the Horizon Europe Regulation¹⁷, a co-design exercise as part of the Strategic Planning process of Horizon Europe led to the identification of **49 candidates for Co-funded, Co-programmed or Institutionalised European Partnerships**¹⁸. Out of these, **13 were identified as suitable candidate Institutionalised Partnerships because of their objectives and scope**¹⁹. Whilst the Co-Funded and Co-Programmed Partnerships are linked to the comitology procedure (including the adoption of the Strategic Plan and the Horizon Europe Work Programmes), Institutionalised Partnerships require the adoption of legislation and are subject to an impact assessment. The Figure below gives an overview of all candidate European Partnerships according to their primary relevance to Commission priorities for 2019-2024.

¹⁷ Horizon Europe Regulation (common understanding), Annex Va.

¹⁸ Shadow configuration of Strategic Programme Committee for Horizon Europe. The list of candidate European Partnerships is described in “Orientations towards the Strategic Plan of Horizon Europe” - Annex 7

¹⁹ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47)

Figure 1 - Overview of the candidates for Co-Funded, Co-Programmed and Institutionalised European Partnerships according to Horizon Europe structure

Source: Technopolis group (2020)

There are only three partnerships for which implementation as an Institutionalised Partnership under Article 185 is an option, i.e. European Metrology, the EU-Africa Global Health partnership, and Innovative SMEs. Ten partnerships are candidates for Institutionalised Partnerships under Article 187. Overall, the initiatives can be categorised into ‘horizontal’ partnerships and ‘vertical’ partnerships.

The ‘horizontal’ partnerships have a central position in the overall portfolio, as they are expected to develop methodologies and technologies for application in the other priority areas, ultimately supporting European strategic autonomy in these areas as well as technological sovereignty. These ‘horizontal’ partnerships are typically proposed as Institutionalised or Co-programmed Partnerships, in addition to a number of EIT KICs, they cover mainly the digital field in addition to space, creative industries and manufacturing, but also the initiative related to Innovative SMEs. ‘Vertical’ partnerships are focused on the needs and development of specific application areas, and are primarily expected to support enhanced environmental sustainability thereby addressing European Green Deal’s objectives. They also deliver on policies for a more people-centred economy, through improved wellbeing of EU citizens and the economy.

2.2. Assessing the necessity of a European Partnership and possible options for implementation

Article 8 of the Horizon Europe Regulation stipulates that Institutionalised European Partnerships based on Article 185 and 187 TFEU shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and

if justified by a long-term perspective and high degree of integration. At the core of this impact assessment is, therefore, the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

For all candidate Institutionalised European Partnerships the options considered in this impact assessment are the same, i.e.:

- Option 0 – Baseline option – Traditional calls under the Framework Programme
- Option 1 – Co-programmed European Partnership
- Option 2 – Co-funded European Partnership
- Option 3 – Institutionalised Partnership
 - Sub-option 3a Institutionalised Partnerships based on Art 185 TFEU
 - Sub-option 3b Institutionalised Partnerships based on Art 187 TFEU

2.2.1. Option 0 - Baseline option – Traditional calls

Under this option, strategic programming for R&I in the priority area will be done through the mainstream channels of Horizon Europe. The related priorities will be implemented through **traditional calls** of Horizon Europe covering a range of actions, mainly R&I and/or innovation actions but also coordination and support actions, prizes or procurement. Most actions involve consortia of public and/or private actors in ad hoc combinations, while some actions are single actor (mono-beneficiary). There will be no dedicated implementation structure and no support other than what is foreseen in the related Horizon Europe Work Programme. This means that discontinuation costs/benefits of predecessor initiatives should be factored in for capturing the baseline situation, when relevant.

Under this option, strategic planning mechanisms in the Framework Programme will allow for a high level of flexibility for traditional calls to respond to particular needs over time, building upon additional co-creation input from stakeholders and programme committees involving Member States. The Union contribution to addressing the priority covers the full duration of the initiative, during the lifetime of Horizon Europe. Without a formal EU partnership mechanism, it is less likely that the stakeholders will develop a joint Strategic Research and Innovation Agenda (SRIA) and commit to its implementation or agree on mutual commitments and contributions outside their participation in funded projects.

2.2.2. European Partnerships

Under this set of options, three different forms of implementation are assessed: Co-funded, Co-Programmed, Institutionalised European Partnerships. These have **commonalities that cannot serve as a distinguishing factor in the impact assessment process**. They are all based on agreed objectives and expected impacts and underpinned by Strategic Research and Innovation Agendas/ roadmaps that are shared and committed to by all partners in the partnership. They all have to follow the same set of criteria along their lifecycle, as defined in the Horizon Europe Regulation (Annex III), including ex ante commitment from partners to mobilise and contribute resources and investments. The Union contribution is defined for the full duration of the initiative for all European Partnerships. The Horizon Europe legal act introduces few additional requirements for Institutionalised Partnerships, e.g. the need for a long-term perspective, strong integration of R&I agendas, and financial contributions.

Figure 2 - Key differences in preparation and implementation of European Partnerships

Type	Legal form	Implementation
Co-Programmed	Contractual arrangement/ MoU	Division of labour , whereby Union contribution is implemented through Framework programme and partners' contributions under their responsibility.
Co-Funded	Grant Agreement	Union provides co-funding for an integrated programme with distributed implementation by entities managing and/or funding national research and innovation programmes
Institutionalised based on Article 185/187 TFEU	Basic act (Council regulation, Decision by European Parliament and Council)	Integrated programme with centralised implementation

The main differences between the different forms of European Partnerships are in their preparation and in the way they function, as well as in the overall impact they can trigger. The Co-Programmed form is assessed as the simplest, and the Institutionalised form as the most complex to prepare and implement. The functionalities of the different form of Partnerships – compared to the baseline option – are presented in Figure 3. They relate to the types of actors Partnerships can involve and their degree of openness, the types of activities they can perform and their degree of flexibility, the degree of commitment of partners and the priority setting system, and their ability to work with their external environment (coherence), etc. These key distinguishing factors will be at the basis of the comparison of each option to determine their overall capacity to deliver what is needed at a minimised cost.

Figure 3 Overview of the functionalities provided by each form of European Partnerships, compared to the traditional calls of Horizon Europe (baseline)

Baseline: Horizon Europe calls	Option 1: Co-Programmed	Option 2: Co-Funded	Option 3a: Institutionalised Art 185	Option 3b: Institutionalised Art 187
Type and composition of actors (including openness and roles)				
Partners: N.A., no common set of actors that engage in planning and implementation <u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning <u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules	Partners: Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology <u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules	Partners: core of national funding bodies or governmental research organisations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> limited, according to national rules of partner countries	Partners: National funding bodies or governmental research organisation <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations	Partners: Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations
Type and range of activities (including additionality and level of integration)				
<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions <u>Additionality:</u> no additional activities and investments outside the funded projects <u>Limitations:</u> No systemic approach beyond individual actions	<u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake <u>Additionality:</u> Activities/investments of partners, National funding <u>Limitations:</u> Limited systemic approach beyond individual actions	<u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake <u>Additionality:</u> National funding <u>Limitations:</u> Scale & scope depend on participating programmes, often smaller in scale	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach <u>Additionality:</u> National funding	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds). <u>Additionality:</u> Activities/investments of partners/ national funding

Baseline: Horizon Europe calls	Option 1: Co-Programmed	Option 2: Co-Funded	Option 3a: Institutionalised Art 185	Option 3b: Institutionalised Art 187
Priority-setting process and directionality				
<u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years. <u>Limitations:</u> Fully taking into account existing or to be developed SRIA/ roadmap	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution Input to FP annual work programme drafted by partners, finalised by EC (comitology) Objectives & commitments set in contractual arrangement	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution Annual work programme drafted by partners, approved by EC Objectives & commitments set in Grant Agreement	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution Annual work programme drafted by partners, approved by EC Objectives & commitments set in legal act	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution Annual work programme drafted by partners, approved by EC (veto-right in governance) Objectives & commitments set in legal act
Coherence: internal (Horizon Europe) & external (other Union programmes, national programmes, industrial strategies)				
<u>Internal:</u> Coherence between different parts of the FP Annual Work programme can be ensured by EC <u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes & activities	<u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC <u>External:</u> Limited synergies with other Union programmes & industrial strategies. If MS participate, with national/ regional programmes & activities	<u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC <u>External:</u> Synergies with national/ regional programmes & activities	<u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC <u>External:</u> Synergies with national/ regional programmes & activities	<u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC <u>External:</u> Synergies with other Union programmes and industrial strategies If MS participate, with national/ regional programmes & activities

2.2.2.1. Option 1 - Co-programmed European Partnership

This form of European Partnership is **based upon a Memorandum of Understanding or a Contractual Arrangement** signed by the Commission and the private and/or public partners. Private partners are represented by industry associations, which also support the daily management of the partnership. This type of partnership would allow for a large degree of flexibility for the activities, partners and priorities to continuously evolve. The commitments of partners are political efforts described in the contractual arrangement and the contributions from partners are provided in kind more than financially. The priorities for the calls, proposed by the Partnership's members for integration in the Horizon Europe's Work Programmes, are subject to further input from Member States (comitology) and Commission services. The Union contribution is implemented within the executive agency managing Horizon Europe calls for research and innovation projects proposals. The full array of Horizon Europe instruments can be used, ranging from research and innovation (RIA) types of actions to coordination and support actions (CSA) and including grants, prizes, and procurement.

2.2.2.2. Option 2 – Co-funded European Partnership

The Co-funded European Partnership is **based on a Grant Agreement** between the Commission and a consortium of partners, resulting from a specific call in the Horizon Europe Work Programme. This form of implementation only allows to address public partners at its core. Typically these provide co-funding to a common programme of activities established and/or implemented by entities managing and/or funding national R&I programmes. The recipients of the EU co-funding implement the initiative under their responsibility, with national funding/resources pooled to implement the programme with co-

funding from the Union. The expectation is that these entities would cover most if not all EU Member States. Calls and evaluations would be organised centrally, beneficiaries in selected projects would be funded at national level, following national funding rules.

2.2.2.3. Option 3 – Institutionalised European Partnership

This type of Partnership is the most complex and high-effort arrangement, and requires meeting additional requirements. Institutionalised European Partnership are **based on a Council Regulation (Article 187 TFEU or a Decision by the European Parliament and Council (Article 185 TFEU))** and are implemented by dedicated structures created for that purpose. These regulatory needs limit the flexibility for a change in the core objectives, partners, and/or commitments as these would require amending legislation. The basic rationale for this type of partnership is the need for a strong integration of R&I agendas in the private and/or public sectors in the EU in order to address a strategic challenge. It is therefore necessary to demonstrate that other forms of implementation would not achieve the objectives or would not generate the necessary expected impacts, and that a long-term perspective and high degree of integration is needed. For both Article 187 and 185 initiatives, contributions from partners can be in the form of financial and in-kind contributions. Eligibility for participation and funding follows by default the rules of Horizon Europe, unless a derogation is introduced in the basic act.

Option 3a - Institutionalised Partnerships based on Article 185 TFEU

Article 185 of the TFEU allows the Union to participate in programmes jointly undertaken by Member States and limits therefore the scope to **public partners** which are Member States and Associated Third Countries. This type of Institutionalised Partnership aims therefore at reaching the greatest possible impact through the integration of national and EU funding, aligning national strategies in order to optimise the use of public resources and overcome fragmentation of the public research effort. It brings together R&I governance bodies of most if not all EU Member States (legal requirement: at least 40% of Member States) as well as Associated Third Countries that designate a legal entity (Dedicated Implementation Structure) of their choice for the implementation. By default, participation of non-associated Third Countries is not foreseen. Such participation is possible only if it is foreseen in the basic act and subject to conclusion of an international agreement.

Option 3b - Institutionalised Partnerships based on Article 187 TFEU

Article 187 of the TFEU allows the Union to set up joint undertakings or any other structure necessary for the efficient execution of EU research, technological development and demonstration programmes. This type of Institutionalised Partnership brings together a stable set of **public and private partners** with a strong commitment to taking a more integrated approach and requires the set-up of a dedicated legal entity – a Union body, Joint Undertaking (JU) – that carries full responsibility for the management of the Partnership and implementation of the calls. Different configurations are possible:

- Partnerships focused on creating strategic industrial partnerships where, most often, the partner organisations are represented by one or more industry associations, or in some cases individual private partners;
- Partnerships coordinating national ministries, public funding agencies, and governmental research organisations in the Member States and Associated Countries;
- Or a combination of the two: the so-called tripartite model.

Participation of non-associated Third Countries is only possible if foreseen in the basic act and subject to conclusion of an international agreement.

2.3. Overview of the methodology adopted for the impact assessment

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines²⁰ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This also integrates **key selection criteria for European Partnerships**.

Box 2 Summary of European Partnerships selection criteria²¹

- **Effectiveness** in achieving the related objectives and impacts of the Programme;
- **Coherence** and synergies of the European Partnership within the EU R&I landscape;
- **Transparency & openness** as regards the identification of priorities and objectives and the involvement of partners & stakeholders from the entire value chain, backgrounds & disciplines;
- Ex-ante demonstration of **additionality** and **directionality**;
- Ex-ante demonstration of the partners' **long term commitment**.

2.3.1. Overview of the methodologies employed

In terms of **methods and evidence used**, the impact assessments draw on an external study covering all candidate Institutionalised European Partnerships in parallel to ensure a high level of coherence and comparability of analysis, in addition to an horizontal analysis.²² For all initiatives, the understanding of the overall context of the candidate institutionalised European Partnerships relied on desk research, including among others the lessons learned from previous partnerships. This was complemented by the analysis of a range of quantitative and qualitative evidence, including evaluations of past and ongoing initiatives; foresight studies; statistical analyses of Framework Programmes application and participation data, and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis).

A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options, as described below. Public consultations (both open and targeted) supported the comparative assessment of the policy options. For each initiative, up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition, the analysis was informed by the results of the Open Public Consultation that ran between September and November 2019, the consultation of Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of initiatives.

A more detailed description of the methodology and evidence base that were mobilised, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

²⁰ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

²¹ For a comprehensive overview of the selection criteria for European Partnerships, see Annex 6.

²² Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Study for the European Commission, DG Research & Innovation

2.3.2. Method for identifying the preferred option

The first step of the assessments consisted in scoping the problems that the initiatives are expected to solve given the overall economic, technological, scientific and social context, including the lessons to be learned from past and ongoing partnerships on what worked well and less well. This supported the identification of the objectives of the initiative in the medium and long term with the underlying intervention logic – showing how to get there.

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has then been adapted to introduce “**key functionalities needed**” - making the transition between the definition of the objectives and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1).

In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options while allowing at the same time a structured comparison of the options not only as regards their effectiveness, efficiency and coherence, but also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)²³.

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made compared to the baseline. Therefore, for each of these aspects, the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. This includes the discontinuation costs/benefits of existing implementation structures when relevant. The policy options are then scored compared to the baseline with a + and – system with a two-point scale, to show a slightly or highly additional/lower performance compared to the baseline. A scoring of 0 of a policy option means that it would deliver as much as the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ – how success would look like – differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different

²³ The criterion on the ex-ante demonstration of partners’ long-term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

types of expected impacts. This is done to increase transparency and accuracy in the assessment of options²⁴.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU's R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach²⁵ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account²⁶. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs of each candidate initiative.²⁷ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership, the costs of preparation and implementation increase only marginally compared to the baseline (<1%), but lead to an additional R&I investment of at least the same amount than the Union contribution²⁸ (efficiency of 98% for the overall investment).
- For a Co-Funded partnership, the additional R&I investment by Member States accounts for 2.3 times the Union contribution²⁹. The additional costs compared to the

²⁴ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

²⁵ For further details, see Better Regulation Toolbox # 57.

²⁶ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

²⁷ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

²⁸ Minimum contributions from partners equal to the Union contribution

²⁹ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).

- For an Article 185 initiative, the additional R&I investment by Member States is equal to the Union contribution³⁰. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution. (efficiency of 96% related to the overall investment).
- For an Article 187 initiative, the additional R&I investment by partners is equal to the Union contribution³¹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution. (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a -Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0		↑↑		
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0		↑↑		
Ex-ante Impact Assessment for partnership		0		↑↑↑	
Preparation of EC proposal and negotiation		0		↑↑↑	
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0		↑		
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC		0			↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of

³⁰ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

³¹ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**)³². In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

For the **identification of the preferred option**, the scorecard analysis builds a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

As a last step, the alignment of the preferred option with key criteria for the selection of European Partnerships is described, reflecting the outcomes of the ‘**necessity test**’.³³ The monitoring and evaluation arrangements are concluding the assessment, with an identification of the key indicators to track progress towards the objectives over time.

2.4. Horizontal perspective on candidate Institutionalised European Partnerships

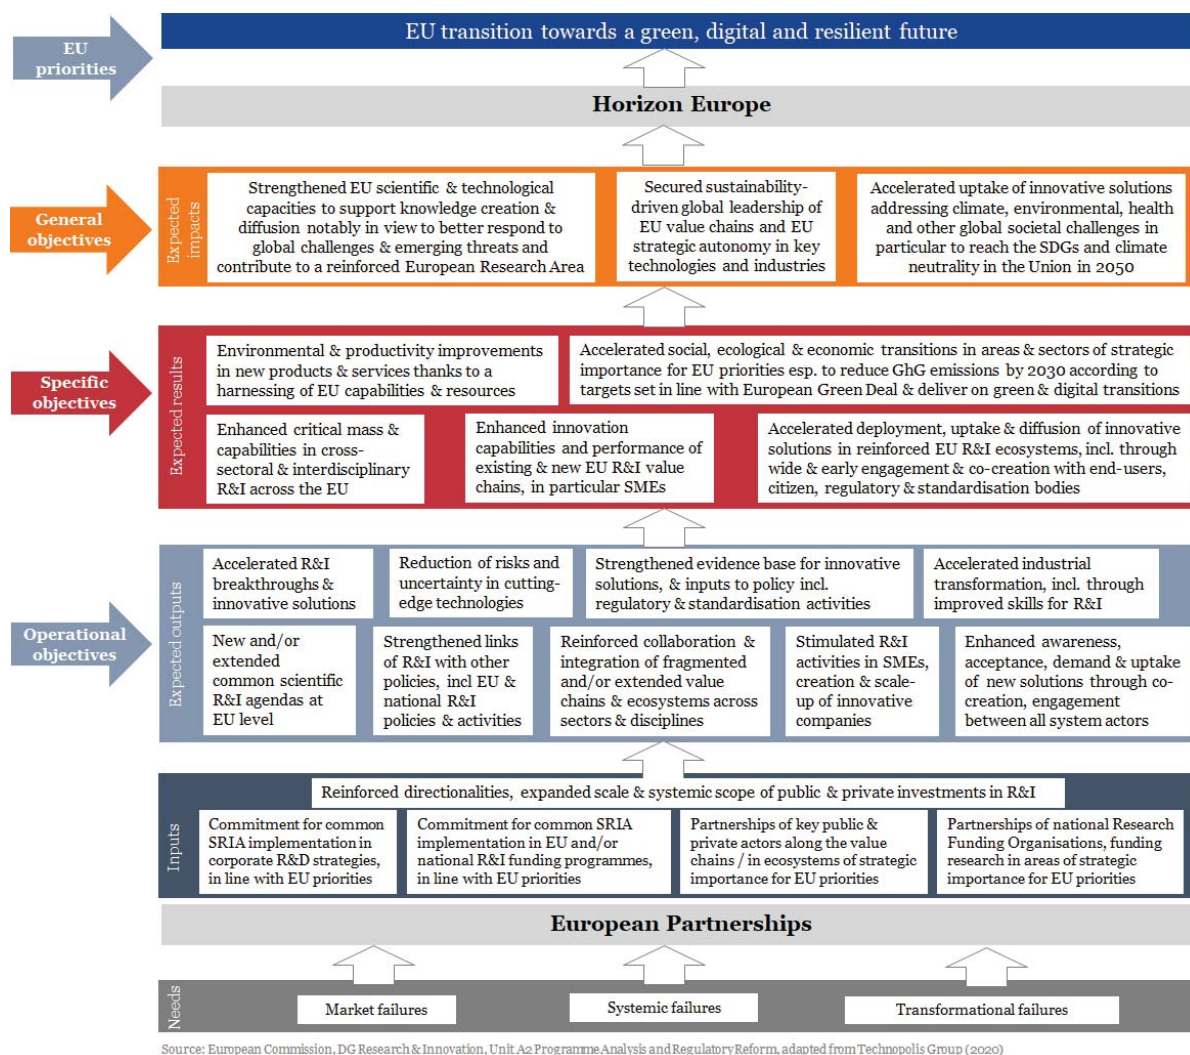

2.4.1. Overall impact orientation, coherence and efficiency needs

The consolidated **intervention logic** for the set of candidate Institutionalised European Partnerships in the Figure below builds upon the objectives as reported in the individual impact assessments.

³² More details on the methodology can be found in Annex 4.

³³ Certain aspects of the selection criteria will be further addressed/ developed at later stages, notably in the context of preparing basic acts (e.g. Openness and Transparency; Coherence and Synergies), in the Strategic Research and Innovation Agendas (e.g. Directionality and Additionality), and by collecting formal commitments (Ex-ante demonstration of partners’ long-term commitment).

Figure 5 – Overall intervention logic of the European Partnerships under Horizon Europe

When analysed as a package the 12 candidate Institutionalised European Partnerships are expected to support the achievement of the European policy priorities targeted by Horizon Europe by pursuing the following joint general objectives:

- Strengthening and integrating EU scientific and technological capacities to support knowledge creation and diffusion notably in view to better respond to global challenges and emerging threats and contribute to a reinforced European Research Area;
- Securing sustainability-driven global leadership of EU value chains and EU strategic autonomy in key technologies and industries; and
- Accelerate the uptake of innovative solutions addressing climate, environmental, health and other global societal challenges contributing to Union strategic priorities, in particular to reach the Sustainable Development Goals and climate neutrality in the Union in 2050.

In terms of specific objectives, they jointly aim to:

- Enhance the critical mass and scientific capabilities in cross-sectoral and interdisciplinary research and innovation across the Union;
- Accelerate the social, ecological and economic transitions in areas and sectors of strategic importance for Union priorities, in particular to reduce greenhouse gas

emissions by 2030 according to the targets set in line with the European Green Deal, and deliver on the green and digital transition;

- c) Enhance the innovation capabilities and performance of existing and new European research and innovation value chains, in particular SMEs;
- d) Accelerate the deployment, uptake and diffusion of innovative solutions in reinforced European R&I ecosystems, including through wide and early engagement and co-creation with end-users, citizen and regulatory and standardisation bodies;
- e) Deliver environmental and productivity improvements in new products and services thanks to a harnessing of EU capabilities and resources.

In terms of their operations, taking an horizontal perspective on all initiatives allows for the identification of further possible collective efficiency and coherence gains for more impact:

- **Coherence for impact:** The extent and speed by which the expected results and impacts will be reached, will depend on the scale of the R&I efforts triggered, the profile of the partners involved, the strength of their commitments, and the scope of the R&I activities funded. To be fully effective, it comes out clearly that future partnerships need to operate over their whole life cycle in full coherence with their environment, including potential end users, regulators and standardisation bodies. This relates also to the alignment with relevant EU, national or regional policies and synergies with R&I programmes. This needs to be factored in from the design stage to ensure a wide take-up and/or deployment of the solutions developed, including their interoperability.
- **Collaboration for impact:** Effectiveness could also be improved collectively through enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems. An adequate governance structure appears in particular necessary to ensure cross-fertilisation between all European Partnerships. This applies not only to initiatives where similar R&I topics are covered and/or the same stakeholders involved or targeted, but also to the interconnections needed between the ‘thematic’ and the ‘vertical’ Partnerships, as these are expected to develop methodologies and technologies for application in EU priority areas. Already at very early stages of preparing new initiatives, Strategic Research and Innovation Agendas and roadmaps need to be aligned, particularly for partnerships that develop enabling technologies that are needed in other Partnerships. The goal should be to achieve greater impacts jointly in light of common challenges.
- **Efficiency for impact:** Potential efficiency gains could also be achieved by joining up the operational functions of Joint Undertakings that do not have a strong context dependency and providing them through a common back-office³⁴. A number of operational activities of the Joint Undertakings are of a technical or administrative nature (e.g. financial management of contracts), or procured from external service providers (e.g. IT, communication activities, recruitment services, auditing) by each Joint Undertaking separately. If better streamlined this could create a win-win situation for all partners leading to better harmonization, economies of scale, and less complexity in supervision and support by the Commission services.

2.4.2. Analysis of coherence of the overall portfolio of candidate initiatives at the thematic level

Looking at the coherence of the set of initiatives at the thematic level, the “**digital centric**”

³⁴ See Annex 6 for an overview of key functions/roles that could be provided by a common back office.

initiatives have a strong focus on supporting the digital competitiveness of the EU ecosystem. Their activities are expected to improve alignment and coordination with Member States and industry for the development of world-competitive EU strategic digital technology value chains and associated expertise. Addressing the Key Digital Technologies, the 5G and 6G connectivity needs as part of a Smart Networks and Services initiative and the underlying supercomputing capacities through a European High Performance Computing initiative present potential for synergies that can be addressed through cooperative actions (e.g. joint calls, coordinated support activities, etc.). They may as well profit from and contribute to Partnerships envisaged for Photonics, AI, data, robotics, Global competitive space system and Made in Europe, together with the EIT Digital. Synergies between these initiatives and several programmes (Digital Europe and Connecting Europe as well as cohesion programmes) are needed in areas where EU industry has to develop leadership and competitiveness in the global digital economy. They are expected to impact critical value chains including on sectors where digital is a strong enabler of transformation (health, industrial manufacturing, mobility/transport, etc.).

The **transport** sector face systemic changes linked to decarbonisation and digitalisation. Large scale R&I actions are needed to prepare the transition of these complex sectors to provide clean, safer, digital and economically viable services for citizens and businesses. Past decades have shown that developing and implementing change is difficult in transport due to its systemic nature, many stakeholders involved, long planning cycles and large investments needed.

A systemic change of the air traffic network through an Integrated Air Traffic Management initiative should ensure safety and sustainability of aviation, while a Clean Aviation initiative should focus on the competitiveness of tomorrow's clean aircraft made in Europe. The initiative for Transforming Europe's Rail System would comprehensively address the rail sector to make it a cornerstone in tomorrow's clean and efficient door-to-door transport services, affordable for every citizen as well as the most climate-friendly mode of transport for freight.

Connected and Automated Mobility is the future of road transport, but Europe risks falling behind other global regions which have strong players and large harmonised markets. The initiative Safe and Automated Road Transport would bring stakeholders together, creating joint momentum in digitalising road transport and developing new user-based services. Stronger links and joint actions will be established between initiatives to enable common progress wherever possible.

The Clean Hydrogen initiative would be fundamental in that regard. Synergies would also be sought with those partnerships driving digital technological developments To deliver a deep decarbonisation of highly emitting industrial sectors – such as the steel, transport and chemical industries – would require the production, distribution and storage of **hydrogen** at scale. The candidate hydrogen initiative would have a central positioning in terms of providing solutions to the challenges for sustainable mobility and energy, but also is expected to operate in synergies with other industry related initiatives.

The initiative would interact in particular with initiatives on the zero emission road and water transport, transforming Europe's railway system, clean aviation, batteries, circular industry, clean steel and built environment partnerships. There are many opportunities for collaboration for the delivery and end-use of hydrogen. However, the Clean Hydrogen initiative would be the only partnership focused on addressing hydrogen production technologies.

Metrology, the science of measurement, is an enabler across all domains of R&I. It supports the monitoring of the Emissions Trading System, smart grids and pollution, but also

contributes to meeting demands for measurement techniques from emerging digital technologies and applications. More generally, emerging technologies across a wide range of fields from biotechnologies, new materials, health diagnostics or low carbon technologies are giving rise to demands requiring a world-leading EU metrology system.

The initiative for a **Circular Bio-based Europe** is intended to solve a shortage of industry investments in the development of bio-based products, whose markets do not have yet certain long-term prospects. The **Innovative Health Initiative** and **EU-Africa Global Health** address the lack of investments in the development of solutions to specific health challenges. The initiative on **Innovative SMEs** supports innovation-driven SMEs in participating in international, collaborative R&I projects with other innovative firms and research-intensive partners. As a horizontal initiative, it is expected to help innovative SMEs to grow and to be successfully embedded in global value chains by developing methodologies and technologies for potential application in the other partnership areas or further development by the instruments of the European Innovation Council.

The description of the interconnections between all initiatives for each Horizon Europe cluster is provided in the policy context of each impact assessment, and further assessed in the coherence assessment for each option.

1. INTRODUCTION: POLITICAL AND LEGAL CONTEXT

Aviation brings major positive social and economic benefits. It connects people, countries and cultures, it enables trade, and generates tourism. Aviation underpins the freedom of movement of persons and goods, one of the European Union founding principles. It connects European citizens and businesses with each other and with the world. Beyond transportation of people and goods, aviation plays a pivotal role in the emergency services, search and rescue, disaster relief, maritime surveillance, police, and border control operations.

The disadvantage is that aviation comes with an environmental cost. Emissions generated by the growing fleet of aircraft, flying with fossil fuels, are rising in line with increasing air traffic.

Reducing fuel consumption has an environmental as well as an economic benefit. Researchers have been successfully reducing fuel consumption by optimising engines and improving the aerodynamic performance of aircraft. Unfortunately, these incremental improvements cannot keep pace with the growth in air traffic, and further large gains within the current technology portfolio seem more and more improbable.

Challenged by the growing environmental concerns, researchers are envisaging several disruptive alternatives to the standard civil aircraft configuration. These include alternative energy sources such as hydrogen or electricity stored in batteries, which could lead to new types of propulsion, innovative aerodynamic configurations reducing air friction, and advanced IT systems that optimise operations.

Such new aircraft technologies come under the term 'Clean Aviation', which is the research and innovation pillar for achieving carbon neutral aviation in the EU by 2050. The complexity of this endeavour lies in the selection and maturing of the most promising technologies, and their demonstration (i.e. integration and testing) in realistic aircraft configurations.

The journey to a climate neutral aviation system is well beyond the private sector's capability and capacity to invest on its own. Equally, no single country in Europe has the financial, technological and industrial capability to affect the transformation, nor the ability to promote and support the required changes to global rules and operative frameworks, which are necessary to implement those solutions.

This document focuses on assessing the most effective, efficient and coherent way of implementing an initiative which would focus on joint European research and innovation activities on Clean Aviation under Horizon Europe.

1.1. Emerging challenges in the field

Aviation is valuable for social and economic development, brings the world closer together and drives global growth and prosperity. While precise data differs slightly depending on the source and calculation methods, all analysis shows significant and sustained growth of both aviation traffic and its ecological footprint.

COVID-19: This growth has been abruptly impacted by the current, on-going COVID-19³⁵ crisis. Thus, it is worth noting that much of the information and data in this impact assessment dates from before the global onset of the COVID-19 crisis. While previous pandemic outbreaks have demonstrated the resilience of the sector to bounce back relatively swiftly, it must be recognised that the COVID-19 crisis is of unprecedented scale and magnitude. A full recovery is not expected before 2025-30.

The expected impact of COVID is explained in more detail in annex 6.2. The evolution of this crisis is being closely monitored by the Commission to ensure that the Clean Aviation initiative reaches its objectives despite the changed economical context.

The aviation sector, which is probably one of the most affected by the crisis, has been the recipient of various national aid packages. The Commission's recent proposals for a post COVID-19 recovery package focus on the European Green Deal as part of the EU's post-pandemic response, with the aim of bridging the gap between economic crisis response and transforming Europe into a sustainable and climate neutral economy.

Stakeholders involved in the CS3PG (the private side's preparatory group for Clean Aviation) underline that the initiative should maintain a clear strategic direction towards climate neutrality, instead of turning towards short-term solutions in response to the current crisis.

The proposed Clean Aviation initiative should not aim to resolve COVID-19 related difficulties but aim at providing a clear strategic direction for the aviation sector and its efforts to become climate neutral.

Environmental concerns:³⁶ ³⁷Over the past decades, the aviation sector has successfully transformed the way Europeans travel and has brought significant socio-economic benefits for people and businesses. Airlines transport over four billion passengers annually, with revenue passenger kilometres totalling nearly eight trillion in 2017³⁸. Air transport carries around 35% of world trade by value and less than 1% by volume.

In 2016, aviation was accountable for 3.6% of the total EU-28 greenhouse gasses emissions and for 13.4% of the emissions from transport³⁹. By 2040, CO₂ and NO_x (nitrogen oxides) emissions are predicted to increase by at least 21% and 16% respectively.

Further growth in aviation would result in a further increase of the adverse impact of carbon dioxide and non-carbon dioxide emissions, as well as from noise, if worldwide investments in new clean and sustainable technologies do not drastically increase. Movements such as "Stay Grounded"⁴⁰ and "Flight Shame"⁴¹ alone could halve the growth in air traffic, according to a survey by the bank UBS⁴².

³⁵ A brief discussion on COVID-19 and its impact on aviation R&I is in annex 6.2.

³⁶ The environmental impact of aviation is discussed in annex 6.3.

³⁷ <https://www.easa.europa.eu/eaer/climate-change/aviation-environmental-impacts>

³⁸ https://aviationbenefits.org/media/166344/abbb18_full-report_web.pdf

⁴⁰ <https://stay-grounded.org/>

⁴¹ <https://www.theguardian.com/money/2019/jun/09/flight-airline-travel-rail-family-environment>

⁴² <https://www.ubs.com/global/en/investment-bank/in-focus/2019/electric-planes.html>

If the aviation sector fails to take effective technology-based measures to address its climate impact, it may be confronted with a range of market based measures which could undermine its growth.

Health concerns: Public health issues, linked to the release of gaseous pollutants, air pollutants and noise emissions, primarily near airports, are a cause of increasing health concerns on the top of disrupted sleep and stress. A report from Queen Mary, University of London⁴³ summarises the strength of evidence for aircraft noise effects on cardiovascular health, sleep disturbance, annoyance, psychological well-being, and effects on children's cognition and learning. The EU has recently confirmed these causal links by embedding them into binding legislation⁴⁴.

1.2. EU relative positioning in the field

The EU is a global leader in this field⁴⁵, with Airbus and the US company, Boeing, operating largely as a duopoly in the global commercial aircraft market. Half of the global commercial aircraft fleet is designed and manufactured by a European company.

Research and innovation is a fundamental building block for European competitiveness and global leadership in the aviation ecosystem. In 2018, the Aerospace and Defence Industries Association of Europe (ASD) estimated that the European aeronautics industry invested EUR 9 billion in R&D annually, although this figure includes product development, which is significantly more expensive than technology development envisaged by the Clean Aviation initiative.

As regards the R&D investments in the field, EU companies are well-positioned compared to the rest of the world according to the 2019 Industrial R&D Scoreboard. The top 39 companies of the aerospace and defence sector in terms of R&D investment invested close to EUR 20 billion in R&D in 2018 worldwide, where EU companies represent 46% of the investments, slightly more than the USA.

In terms of scientific performance, the EU-28 shows a good performance compared to the rest of the world based on scientific publications in the field of aerospace engineering. Based on Scopus data, EU-28 publications represents 23% of all publications in the field with close to 40,000 publications between 2014 and 2019, involving close to 60,000 authors. Worldwide the most prolific country is China with more than 50,000 publications, followed by the United States (40,000).

In terms of technological performance, between 2010 and 2016 the EU overall has maintained a stable higher performance compared to the USA.

In terms of aviation R&I performance and in particular on **patents and scientific publications**, Europe shows strong leadership, especially in peer-reviewed publications and references with high impact factor.

⁴³https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/446311/noise-aircraft-noise-effects-on-health.pdf

⁴⁴ Commission Directive 2020/367 ... as regards the establishment of assessment methods for harmful effects of environmental noise
[https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=uriserv%3AOJ.L_.2020.067.01.0132.01.ENG&toc=OJ%3AL%3A2020%3A067%3ATOC]

⁴⁵ An overview of the positioning of the European industry in aviation is available in annex 6.3.

- Out of the 50 journals on aerospace engineering⁴⁶ worldwide, 26 are based in Europe, including a clear lead in the total citations over the last three years.
- In terms of patents, leading European aeronautics companies hold an extensive portfolio (Airbus⁴⁷: 37,000, Safran⁴⁸: 38,000, Thales⁴⁹: 15,000).

When looking in the EU industrial R&D Scoreboard at the share of green patenting with respect to the total technological inventions of the biggest R&D investors worldwide, the highest share of green over total patents is revealed by companies operating in transport-related industries, including aerospace and defence (23.2%), totalising almost 3,900 green over more than 17,000 patents in the period 2012-2015, and automobiles and other transports (20.1%). These companies concentrate their green inventions in green transportation technologies. From the top 25 green inventors among the top R&D investors, green patents represent 28% of the patents of the company United Technologies (USA), 20% of the patents filed by Airbus (EU), and 34% of the patents filed by Rolls Royce (UK).

Figure - Green patent intensities of top R&D investors by industry;

Note: Share (left panel) and number of green patents (right panel) by industry (ICB) and environmental technology (CPC), 2012-2015. Caption: CCS = "Carbon Capture and Storage", ICT = "Information and Communication Technologies" CCAT =

Finally, a report from Intereconomics on the impact of Horizon 2020 on innovation in Europe confirms (table 3⁵⁰) that Europe has technological advantages in aerospace.

Hence, Europe is in an excellent position to contribute to a clean aviation on condition that all the available R&I resources are mobilised for this research and innovation effort.

Box 3 Support for the field in the previous Framework Programmes⁵¹ – key strengths & weaknesses identified.

Below is a summary of different sources of evidence on the performance of Clean Sky 2, which includes the mid-term evaluation⁵² but also inputs from the study for this impact assessment.

The Clean Sky initiatives⁵³

Dedicated R&I activities related to transport and aviation in particular have been supported since 1994 (FP4) through the Framework Programmes. This covers traditional (collaborative) projects but also support provided through the Clean Sky Joint Undertakings (CS1 and CS2) under Horizon 2020.

The Clean Sky Joint Undertaking is a partnership between the EU and the aviation

industry set up in 2008, with a total budget of EUR 1.6 billion for CS1 and EUR 4bn for CS2 and focussing on delivering technologies for reducing aircraft emission.

More than 75% of the EU aviation research funding in Horizon 2020 was provided through CS2, whereas under FP7, CS1 only accounted for just under 50% of the total EU research funding.

The maximum EU contribution to CS2 is EUR 1.7 billion, to be funded from Horizon 2020⁵⁴. The private members of the JU are expected to contribute resources of at least EUR 2.2 billion over the life span of the JU. Of this amount, private members have to incur costs of at least EUR 965 million in implementing additional activities outside the work plan of the Clean Sky Joint Undertaking. Details on the way the Joint Undertaking functions are available in annex 2.7 and annex 2.8.

What has or is being achieved so far?

Numerous promising climate neutral solutions have been researched under former public and private research and innovation programmes, either in the EU (starting from the 4th research and development programme), national or regional programmes. A number of those technologies, that reached high maturity levels in the Clean Sky and Clean Sky 2 research programmes, have been assessed in the Technology Evaluator under FP7-Clean Sky and it was found that if taken-up in new aeroplanes, they have the potential to reduce emissions up to 30% compared to a state-of-the-art aircraft available on the market in the year 2000.

⁵¹ Annex 6.8 provides an introduction to the H2020 aviation research landscape

⁵² <https://ec.europa.eu/research/evaluations/pdf/cs2.pdf>

⁵³ The Clean Sky public-private partnerships are detailed in annex 6.7. A more complete overview of the European aviation research is available in annex 6.5.

⁵⁴ Article 3(1) of Regulation (EU) No 558/2014

Technological advances in aviation have significantly impacted aviation emissions; current aircraft are about 80% more fuel efficient, per passenger kilometre, than aeroplanes in the 1960's.

The Interim Evaluation⁵⁵ of the Joint Undertakings operating under Horizon 2020⁵⁶ concluded that JU-based public-private partnerships (PPPs) have demonstrated efficiency improvements in comparison to FP7, despite a few identified shortcomings to be addressed.

While it is too soon to draw conclusions for CS2 (which runs until 2024), preliminary assessments show that it is well on track to achieve its objectives of demonstrating and validating technologies reducing CO₂ and NO_x emissions by 20 to 30% compared to state-of-the-art aircraft entering into service as from 2014⁵⁷. A growing number of publications and patent applications support the good progress of the main demonstrators⁵⁸. Unfortunately, the introduction of those technologies into aeroplanes on the market is anything but certain, because this is largely determined by market forces.

CS2 has been successful in attracting over 800 participants – including industry, research and technology organisations (RTOs), academia, and many SMEs – with a good geographical distribution. However, funding is concentrated within a limited number of industrial leaders, core partners and their associated supply chain with a large part of the funding (40%) earmarked upfront for the Leaders⁵⁹ and Core Partners (30%) and only the remaining 30% available through open calls.

What are the key areas for improvement⁶⁰ & unmet challenges?

The Interim Evaluation of CS2⁶¹, published in 2017, raises various questions, summarised below and outlined in more detail in annex 2.10 (see also the study by Steer and Technopolis supporting which⁶² identified a set of issues from the experience of the CS2 JU).

The summary of the issues across both reports is:

Concentration of funding

- Project participation rates are distributed in favour of a relatively limited number of organisations. A large share of the funding is reserved to Leaders and Core Partners. There is a risk that SMEs or EU-13⁶³ Member States participants may find it difficult to join it, as project participation in the CS2 JU is concentrated among a relatively limited number of players reflecting the composition of Leaders and Core Partners.

⁵⁵ More information on the Interim Evaluation, its recommendations and the initial Clean Aviation response are available in Annex 6.7.3

⁵⁶ Commission SWD - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, {SWD (2017) 339 final}

https://ec.europa.eu/research/evaluations/pdf/20171009_a187_swd.pdf

⁵⁷ https://www.cleansky.eu/sites/default/files/inline-files/CS-GB-2019-06-27%20AAR%202018_published.pdf

⁵⁸ Clean sky 2 Annual Activity report 2019

⁵⁹ The structure of the Clean Sky and Clean Sky 2 programmes are explained in Annex 6.7

⁶⁰ A brief overview of the Clean Aviation responses to clean sky 2 perceived shortcomings is available in annex 6.11

⁶¹ <https://ec.europa.eu/research/evaluations/pdf/cs2.pdf>

⁶² Technopolis Group, Steer (2020, forthcoming), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe -Candidate Institutionalised European Partnership on Clean Aviation

⁶³ Bulgaria, Croatia, Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Romania, Slovakia and Slovenia

- The imbalance between the relatively small budget for collaborative aviation R&I, over the last decade, compared to the large budget for demonstration, has adversely affected the availability and spectrum of lower technology readiness levels (TRL)⁶⁴ technologies to the European aviation research chain.

Operations

- Aspects of the design and implementation of the CS2 JU have limited effectiveness: certain aspects of its governance arrangements such as the role of the States' Representative Group, which is not always as well attended as could be and its opinions are only advisory.
- The lack of structural involvement of the European Union Agency for Safety Aviation (EASA) in CS and CS2 may have a negative impact on the “time to market”, which benefits from the assessment of potential safety risks and environmental standards related to certification of new products and technologies. Safety topics and certification issues regarding environmental protection may also have been excluded from the scope of CS2 R&I by narrow industrial interests.
- Similarly, the CS2 JU complex membership structure is constraining the R&I effort. There is arguably a need for greater flexibility and for reduction in the administrative burden. There are also some communication improvements that could be made.
- It is not always easy to establish what the precise outcomes of CS1 and CS2 have been.

Policy coordination

- There is a lack of multi-level policy coordination, e.g. between the EU and Member States' level, whilst horizontal coordination between research, technology and innovation policies is good in the European aviation sector.
- Although some Member States have quite elaborated aviation research programmes, one of the weaknesses of the European research landscape is that there is no systematic alignment, and no single roadmap, of the various aviation related research programmes leading to overlaps, ineffective investment and sometimes to duplications.
- Overall, the CS2 programme has not contributed to the alignment of national and EU aviation research programmes – apart from creating some synergies with EU regional funds⁶⁵ as outlined in the CS2 2018 Annual Activity Report. In addition, efforts to develop more electric systems as well as composite aero structures were often duplicated by partners, while opportunities for synergies were not exploited.

In addition, the interim evaluation of CS2 recommended increased transparency and energising academic participation to better spread the newly acquired knowledge.

1.3. EU policy context beyond 2021

Aviation research has been of particular interest for the EU since the fourth framework programme. However, the political context has evolved drastically in the last five years with all Member States of the EU having signed and ratified the Paris Agreement, and the EU committing to contributing to delivering the Sustainable Development Goals (SDGs).

⁶⁴ https://ec.europa.eu/research/participants/data/ref/h2020/other/wp/2016-2017/annexes/h2020-wp1617-annex-ga_en.pdf (Annex G for a definition of Technology Readiness Levels)

⁶⁵ https://www.cleansky.eu/sites/default/files/inline-files/CS-GB-2019-06-27%20AAR%202018_published.pdf

In order to contribute to EU policies, as well as increasing the integration of aviation research into relevant policies, the forthcoming Clean Aviation initiative must take into account the surrounding environment and the regulatory framework.

Policy communications provide the direction the initiative should follow:

- In 2018, the European Commission published “A Clean Planet for All”⁶⁶, the strategic long-term vision of the EU for a prosperous, modern, competitive, and climate-neutral economy by 2050.
- The European Green Deal⁶⁷ puts a high emphasis on preventing climate change and protecting the health of citizens especially children. It identifies, through research and innovation, a way to drive the transformation to modernise the EU’s economy and society and re-orient them towards a just and sustainable future and becoming the world’s first climate-neutral continent by 2050.
- The COVID-19 recovery package⁶⁸ is presented as an opportunity to redesign a sustainable, inclusive economy, revitalising industry, preserving vital biodiversity systems, and tackling climate change.

The European Green Deal Communication specifically mentions aviation, suggesting market-based measures such as a revision and strengthening of the EU Emissions Trading Scheme (ETS⁶⁹) which could trigger aviation stakeholders to develop more environmental friendly practice.

The European Green Deal Communication further aims at the improvement of air quality near airports by tackling the emissions of pollutants by aeroplanes and airport operations, and the modernisation of Trade Defence Instruments.

The European Green Deal will also re-orient the lending policy of the European Investment Bank⁷⁰. European Investment Bank (EIB) financing and InvestEU can be effective multipliers in areas of the supply chain where access to commercial finance is limited. An important option could be ‘green finance’ for airlines: enabling earlier and more aggressive rollout of new aircraft in their fleets.

The implication for an R&I initiative on Clean Aviation is that breakthrough technologies based on green energy sources become more attractive for the market, in turn motivating the acceleration of clean aviation research.

The EU is investigating the use of EU and/or global emissions trading schemes to foster further improvements in air quality, as well as greater use of sustainable aviation fuels that have lower emissions.

The ECOFIN Council on 5 December 2019⁷¹ gave its support to an update of the legal framework for energy taxation (including aviation, taking into account their specificities and

⁶⁹ https://ec.europa.eu/clima/sites/clima/files/factsheet_ets_en.pdf

⁷⁰ https://ec.europa.eu/commission/presscorner/detail/en/qanda_20_24

⁷¹ <https://www.consilium.europa.eu/media/41646/st14851-en19.pdf>

existing exemptions and international dimension), which will contribute to wider economic and environmental policy objectives⁷².

- **Regulations** put the boundaries for the initiative to operate while supporting sustainability-driven innovation in the sector. Two directives regulate aviation noise, mainly at airports. Directive 2000/14/EC on noise emitted by non-transport outdoor equipment, and Directive 2002/49/EC on noise mapping. These two pieces of legislation are currently under revision in order to be aligned with the recent World Health Organisation guidelines. The implication for an R&I initiative on Clean Aviation are similar as for previous point.

In Horizon Europe, the aviation research is part of the research and innovation activities under Cluster 5 “Climate, Energy and Mobility” under pillar 2. Aviation has been identified as one of the industry sectors with the highest need for new technological solutions to contribute to meeting the goals of the Paris Agreement, such as sustainable mobility and health.

The proposed mandate and scope of the Clean Aviation initiative is to focus exclusively on highly disruptive new technologies with the greatest potential to contribute to the ambitious European Green Deal objective of full decarbonisation by 2050;

The Horizon Europe collaborative calls for proposals should, in turn, concentrate on lower TRL research, including topics covered by the new industrial strategy⁷³ and the European digital agenda⁷⁴;

This two-pronged approach enables a very focussed Clean Aviation initiative alongside a highly complementary collaborative research programme.

Other aspects of the aviation sector’s comprehensive decarbonisation strategy (e.g. incremental improvements in energy efficiency of engines and aircraft design, drop-in sustainable aviation fuels) should be supported by industry’s own R&D budgets, or by national resources.

A **set of policies are relevant** to be considered as regards the field of clean aviation, in particular:

Trade policies: Both the EU and the USA have been found at fault by the WTO dispute settlement system⁷⁵ for continuing to provide certain unlawful subsidies to their aircraft manufacturers.

Industrial policies: This includes the linkages between European strategic value chains that have been identified⁷⁶ and integrated industrial aviation activities with great potential to contribute to Europe’s green and digital transformation and to improve Europe’s industrial competitiveness.

⁷² More information is available in the external studies, performed on behalf of the European Commission, which are linked with the EU-ETS and new sustainable energy carriers for aviation towards 2050.

⁷³ https://ec.europa.eu/info/strategy/priorities-2019-2024/europe-fit-digital-age/european-industrial-strategy_en

⁷⁴ https://ec.europa.eu/info/sites/info/files/communication-shaping-europes-digital-future-feb2020_en_4.pdf

⁷⁵ <https://trade.ec.europa.eu/doclib/press/index.cfm?id=2068>

⁷⁶ Report of the Strategic Forum for Important Projects of Common European Interest, EC, DG GROW.

Competition policies: Considering that, in 2019, the global aerospace and defence mergers and acquisitions increased by 62% to EUR 86 billion⁷⁷, when compared with 2018, it is of importance to safeguard the intellectual property rights (IPR) of the European aviation supply chain as a result of EU-funded pre-competitive R&I.

Energy policies: In line with the Energy Union objectives for transport towards achieving deep emissions reductions, aviation R&I paths will need to contribute to the required integrated system approach for overall aircraft efficiency.

Transport policies: In line with the objectives of the European Strategy on Sustainable and Smart Mobility, towards achieving 90% reduction in emissions by 2050, due consideration should be taken of all four principles that will guide transport's contribution to the European Green Deal:

- Making the transport system as whole more sustainable;
- Making sustainable alternative solutions available to EU citizens and businesses;
- Respecting the polluter-pays principle in all transport modes;
- Fostering connectivity and access to transport for all.

In addition, the policy context is also influenced by the European Aviation Strategy⁷⁸ (including the objectives towards a Single European Sky) as well as all initiatives towards a transparent and effective phase 4 trading period (2021-2030)⁷⁹ of the EU Emissions Trading System (i.e. ending fossil-fuel subsidies, revising the Energy Taxation Directive, addressing current tax exemptions, and reducing the quantity of free allowances allocated to airlines).

Health policies: In post-COVID-19 times, attention needs to be paid to communicable diseases in all public transport vehicles and their infrastructures. European aviation R&I needs to take account of related mitigation and preparedness actions, with an eye towards the next outbreak. Technological and societal solutions should be in-line with the national and European health plans, ECDC⁸⁰ and ICAO revised guidelines. Preliminary considerations are laid out in Annex 6.2.4.

The initiative has to operate in synergy with its environment to support the adoption of clean technologies. In particular supporting horizontal synergies and efficiencies beyond Horizon Europe, other instruments and initiatives can take the partnership's activities further and strengthen its impact:

- The Connecting Europe Facility (CEF) can facilitate market uptake where deployment is strongly dependent on infrastructure development.
- As is currently developing, the link to the European Innovation Council (EIC) can provide significant opportunities for transferring R&I results delivered by SMEs into the next phase of development and market deployment.
- Other European Partnerships might be a source of solutions or of markets for Clean Aviation solutions:
 - For technology solutions: e.g. the Clean Hydrogen initiative
 - For improved digitalisation: e.g. the Key Digital Technologies initiative

⁷⁷ <https://www.pwc.com/us/en/industries/industrial-products/library/aerospace-defense-quarterly-deals-insights.html>

⁷⁸ <https://eur-lex.europa.eu/legal-content/EN/ALL/?uri=COM:2015:598:FIN>

⁷⁹ https://ec.europa.eu/clima/policies/ets/revision_en

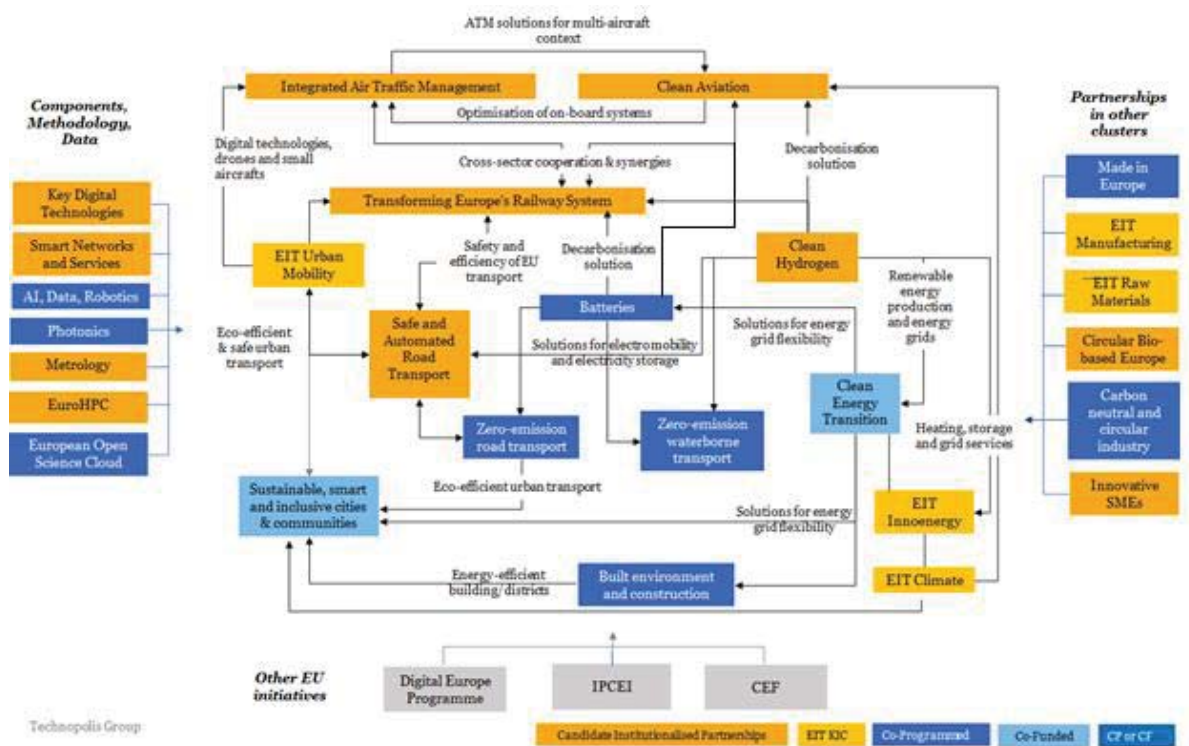

⁸⁰ <https://www.ecdc.europa.eu/en/covid-19-pandemic>

- For improved deployment: e.g. the Integrated Air Traffic Management initiative

A separate institutionalised partnership (to succeed the SESAR Joint Undertaking) is proposed to optimise air traffic control and co-ordination between national authorities in this area. A mapping of the potential links between the different initiatives put forward as candidate European Partnerships under this cluster is provided in the Figure below. These potential links are explained in annex.

Overall, an initiative on Clean Aviation would have a set of potential interconnections with other partnerships. This highlights the five possible candidate initiatives and the synergies between them and with other initiatives. Four of these can be considered as ‘application’ sector partnerships with the other (Clean Hydrogen) being more ‘technology’ orientated. The central position of batteries and hydrogen, as enablers of zero emission transport and the clean energy transition, is also clear from the analysis. Likewise, there are synergies with the other technology-related partnerships, particularly in the digital area, and those that are manufacturing or materials-orientated. This also highlights the twin challenges of digitisation and decarbonisation for the future energy/mobility sectors.

Potential interconnections between partnership initiatives in the Climate, Energy and Mobility cluster of Horizon Europe

2. PROBLEM DEFINITION

2.1. What are the problems?

Given the scale of the challenges ahead for achieving the European Green Deal in aviation, the current scientific, technological and economic positioning of Europe in the field, and the

overarching EU policy context, a set of problems have been identified where there is a need for EU research and innovation in the field of Clean Aviation.

2.1.1. Growing ecological footprint of aviation associated to unclear path to climate neutrality

The growing demand for air-transport of passengers and goods, expected to swiftly pick up again after COVID, is insufficiently offset by incremental technological and operational improvements, as well as market-based measures, to reduce the environmental externalities of aviation. This is not consistent with the EU's objective of climate neutrality by 2050 and EU citizens' expectations.

The technological path towards climate neutrality is not obvious in aviation, and established solutions in other sectors cannot simply be transferred, due to severe constraints like weight and/ or performance (e.g. batteries⁸¹), safety or scalability issues.

Some of the most interesting research paths identified so far – clean hydrogen (for which there are currently no established large green supplies) and electrification with batteries – will require huge investments not only for powering new aircraft but also for renewing airports and infrastructure worldwide to enabling this shift of technology.

All this has global consequences on climate change, serious health implications especially for people living near airports, and it puts the prosperity of the European aviation industry in danger. This could have wider effects on mobility and connectivity which are important for the European integration project.

A Clean Aviation initiative should concentrate on disruptive technologies with high potential to accelerate the development of climate neutral aviation technologies for the earliest possible deployment in view of the European Green Deal targets for 2030 and 2050. Within the context of the deadlines set by the European Green Deal, selecting the most promising technologies should include an assessment on how fast these could be brought to the market.

2.1.2. Insufficient deployment of EU R&I aviation solutions putting EU European industrial leadership & technological sovereignty at risk

The current incremental pace of innovation is largely set by the global context in which European aviation is operating. Europe is manufacturing roughly 50% of all civil aircraft worldwide and has a very good performance in terms of green patenting in aviation. Looking at the European aviation value chain as a whole, it is designing and manufacturing each significant part of a civil aircraft.

While the ability to design, prototype and patent every aspect of a radical innovative design in combination with the strong policy drive (and linked public support) puts Europe in an excellent position to contribute to clean aviation, it should not be forgotten that only a competitive European industry can put the necessary focus on the needed technological breakthroughs to achieve climate neutrality while upcoming international competitors are competing on price, not quality.

⁸¹ With current technology, the weight of the batteries required for normal flight operations of an airliner would have the order of magnitude of 100+ tons and exceed the maximum take-off weight. (source: Airbus)

Potential clients weigh the purchase costs, performance advantages, operational and expected maintenance costs of the various aircraft on offer. This way, an innovative design may price itself out of the market compared to much cheaper, less advanced aircraft.

One technological challenge is to significantly accelerate technology development and tap into technologies emerging from other sectors with potential for adoption in aviation while ensuring that this does not lead to a higher sales price.

In fact, the “market” for breakthrough technologies has largely been created by the European Green Deal. Without this strong policy drive and support, it would be impossible, even with the resources of the combined European aviation industry, to justify developing civil aircraft using alternative energy sources such as hydrogen and/or through electrification with batteries.

In addition, there are no shortcuts on safety in aviation. Safety is a fundamental objective embedded in any aviation R&I effort. The prior indication that an innovative climate neutral solution has reasonable chances to be certified by the regulatory bodies is of major importance to drive research and innovation.

As an illustration, the two main demonstrators in terms of Clean Sky 2 achievements (the BLADE wing design, and the CROR open rotor) aiming at increasing the environment performance of aircraft have not been taken up by the market on the ground that they were not certified.

The aviation sector is a highly internationally regulated market, characterised by very long lifecycles. Emerging technological R&I solutions to reduce the environmental impact of the aviation industry (e.g. electrified aircraft, hydrogen), require long development and demonstration cycles compared to other modes of transports. Access to the global market for the European industry, and for very innovative products, is heavily dependent upon the corresponding standardisation efforts, and on ensuring world-wide regulatory convergence in the field of certification and common rule making. As with all global regulation and standardisation, this is often a complex and lengthy process.

In addition to the research, product development and related certification prohibiting cost, the huge investments required by airports to store hydrogen, or supply electricity to the aircrafts would prevent any such breakthrough technology from reaching the market.

The current certification regulatory framework does not sufficiently allow for the early certification of more promising climate neutral solutions. Certification – although its value and necessity is not questioned – tends to delay market introduction of innovations.

2.1.3. Fragmented R&I capacity of the European aviation value chains prevents to develop climate neutral technologies within the Green deal delays

The European Green Deal deadlines of 2030 and 2050 pose a challenge on their own and introduce a sense of urgency in a sector used to work with very long life-cycles and carefully planned introduction of new technologies on the market.

The initiative will have to pay particular attention towards analysing options for the most promising technologies, to tap into the most knowledgeable sources for individual R&I issues and to define and continuously refine the most efficient critical path towards the delivery of the envisaged demonstrators.

Without such careful analysis, and sufficient attention for review, testing and certification throughout the R&I process to ensure that cleaner aviation remains safe, secure and efficient the introduction of the radically new technologies required to achieve the green deal targets could be impossible.

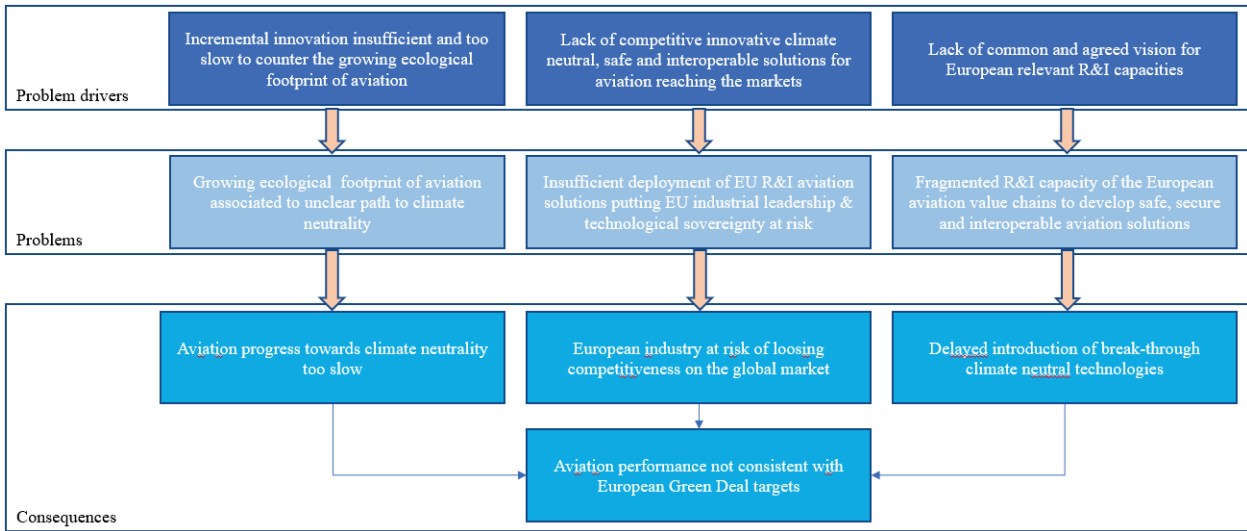

In view of the limited resources compared to the highly ambitious targets of the Clean Aviation initiative, synergies with national aviation R&I programmes will be key to achieving the objectives. The absence of systematic cooperation with these programmes reduces efficiency of aviation research overall, potentially with solutions to occurring problems hidden at a national level, only partially investigated, or investigated in parallel in different countries.

This fragmentation in aviation R&I actions could be addressed by policy actions seeking alignment of the national and European schemes for R&I.

Many of the stakeholders responding to the **Open Public Consultation** confirmed the importance of these issues. A substantial majority of business organisations, business associations, academic and research institutions, public authorities and EU citizens strongly recognise the impact that long development and innovation cycles and high associated costs of demonstration are having on the growing ecological footprint, whilst all parties also recognise that a future initiative in the area must also make significant contributions to EU global competitiveness.

These themes were echoed during the **interviews**, with several stakeholders (from across industry, Member States, academics and research institutes) also highlighting the long development and innovation cycles and high associated costs as contributing to the growing ecological footprint, and that a transformative change was required to achieve sustainability in the industry, despite the practicalities of this being unclear at this stage. Most stakeholders noted the importance of EU industrial leadership in the field, especially in the face of increasing competition from China and Russia. Many business stakeholders also expressed the need for the industry to deliver cost-efficient products that would be affordable for their airline customers.

2.2. What are the problem drivers?

2.2.1. Incremental innovation insufficient and too slow to counter the growing ecological footprint of aviation

Whilst advancements in technology reduce the average fuel consumption and emissions per passenger by -1.5 % per annum, the 4.4% average annual passenger growth more than counteracts this, resulting in fuel consumption and emissions rising by approximately +2.9% per annum or doubling every 25 years⁸². Without transformative interventions in next generation aircraft, the aviation industry's CO₂ emissions will be approximately 136% higher in 2050 compared to 2020⁸³.

As shown in the Figure below, ICAO's schematic CO₂ emission reduction roadmap highlights the effects of different measures on the aviation industry from 2020. It shows (in green) that improvements to current aircraft technologies, infrastructure and operating procedures are not sufficient to achieve carbon-neutral growth in the context of growing levels of air traffic.

ICAO's schematic CO₂ emissions reduction roadmap for the aviation industry

Source: Eurocontrol (2019), Think Paper #4, Decarbonisation Issues

⁸² Source: European Commission, PRIMES scenario, https://ec.europa.eu/clima/policies/strategies/analysis/models_en

⁸³ European Commission (2018), Global Energy and Climate Outlook 2018: Sectoral mitigation options towards a low-emissions economy – see:

http://publications.jrc.ec.europa.eu/repository/bitstream/JRC113446/kj1a29462enn_gcco2018.pdf

Instead radically new technologies and sustainable aviation fuels are required (blue zone in the drawing below) to address the substantially increased level of EU aviation CO₂ emissions (+95% from 1990 to 2016)⁸⁴.

Economic measures could decrease the demand and thus control the growth of emissions. These would, however, also reduce airline profitability leading to reduced investments in new aircraft and technologies. If such activities were not coordinated at a global level, competitors from outside Europe who are less impacted by these measures would get a competitive advantage compared to European companies.

They would, therefore, need to be carefully designed to incentivise airlines to invest faster in greener technologies or accelerate the demand for sustainable aviation fuels for which there are, currently, no proper alternatives for long-haul flights.

In light of the above graph, incremental technology gains will not lead to climate neutrality.

2.2.2. *Lack of competitive innovative climate neutral, safe and interoperable solutions for aviation reaching the markets*

Commercial aircraft combine a wide range of different, complex, and interacting components for aerodynamics, propulsion, navigation, and communication. The components’ integration is crucial for safe and effective aircraft performance. As one example of this complexity, Airbus has more than 12,000 suppliers worldwide. The main parts of the popular A320 series⁸⁵ are constructed in seven countries with final assembly in three factories in three different countries one three different continents.

The complex interaction of components makes it very hard to predict if a new design will (under all possible) real-world circumstances behave exactly as predicted, based on theoretical and computational models. This is already true for the traditional civil aircraft configuration, and it certainly applies when moving into the uncharted territory of alternative propulsion (hydrogen, batteries) systems, innovative aerodynamic (blended wing) designs, and the accelerated introduction of digitalised systems. Testing of aircraft functionality and safety is therefore a crucial but timely and costly part of the R&I process.

From conception phase (TRL 1) through all the steps of maturing the technologies to “fit-to-fly” (TRL 9) typically takes between 10 and 20 years (see Figure below), including substantial financial investment. The consequences of bringing design errors to the market could include the loss of life, disruption of the aviation and tourist sector as a whole by grounded planes, economic disaster for the aeronautical supply chain, and potential bankruptcy of the integrator.

Time to mature aircraft technologies

This is the reason why aircraft manufacturers are very careful when introducing new technologies and, more often than not, limit themselves to the gradual roll-out of incremental improvements.

The Commission Staff Working Document on better regulations for innovation-driven investment at EU level⁸⁶ underlines that cost, time and uncertainty related to certification are important factors in preparing new aviation products and services. Certification can indeed add three to five years of additional delay after an accumulated 10 years of investments costs (accumulating credit/debt) also postponing sales.

Due to high costs associated with the production process of aircraft, manufacturers seek to receive certification for their aircraft quickly and the early involvement of regulators in research and the deployment of emerging technologies can reduce time to market significantly.

An extra dimension is the long life-span of aircraft once on the market⁸⁷. Although the life-span of a commercial aircraft is declining, it is still fairly common for civil aircraft to be used for a period between 20 to 30 years or longer. It may be expected that the COVID-19 outbreak will lead to an increase in those average life spans of civil aircraft and slower replacement of older, less environmentally friendly aeroplanes by the newest models.

The European Union Aviation Safety Agency (EASA⁸⁸) benefits in the implementation of its tasks from early knowledge sharing between regulators and industry (while ensuring regulator independence), as aspects of the design, production, and servicing of aircraft become more dispersed⁸⁹. To be noticed though that acceleration of safety critical technologies (such as aircraft-based flight control) without timely, proper, and independent oversight can lead to fatal outcomes.

Unable to compete on price with upcoming new aircraft manufacturers, the maintenance of Europe's leadership position in the global aeronautical market in an increasingly competitive environment depends on R&I leading to technological excellence in turn leading to cost efficiency, offering a far better performance to airlines compared to cheaper products from upcoming manufacturers.

To sustain Europe's leadership position and thus make green aircraft globally available, the Clean Aviation initiative has to focus on those new technologies that brought to market could maintain the European competitive lead over the competing products from international competitors.

⁸⁶ <https://op.europa.eu/en/publication-detail/-/publication/404b82db-d08b-11e5-a4b5-01aa75ed71a1/language-en/format-PDF/source-79728021>

⁸⁷ http://www.boeing.com/assets/pdf/commercial/aircraft_economic_life_whitepaper.pdf

⁸⁸ A short contribution on the role of EASA in research and innovation is available in annex 6.6.

⁸⁹ EASA (2019), Emerging Technologies and Aircraft Certification – accessible at http://congress.cimne.com/emus2019/frontal/doc/PL_Abstract/PL_Abstract_Waite_Expert.pdf

2.2.3. *Lack of common and agreed vision for European relevant R&I capacities*

The Flightpath 2050 (ACARE's Vision for Aviation) only provides a general umbrella but in practice, a coordinated roadmap and workload share are not available. In addition, Flightpath 2050 environmental ambitions have to be revised and made more ambitious in relation to the European Green Deal.

Under H2020 and on the European level, cooperation between the two aviation Joint Undertakings (Clean Sky and SESAR) is based upon a memorandum of understanding between the two Joint Undertakings. This cooperation is limited to an exchange of information and preventing overlapping research projects. Coordination is also limited between the European collaborative research programme for aviation, and the Clean Sky demonstrator programmes.

Next to the European aviation research and innovation programmes there are national aviation R&I programmes with significant budgets such as those of Germany (LuFo), France (CORAC) and the UK (ATI), with a budget of between EUR 2-3 billion for a period of five years.

However, an external study shows that these programmes were not sufficiently coordinated, neither at national level nor at European level. In some cases, national interest in local employment and technology, led to non-complementary policies, with a possible duplication of activities.

Under Horizon 2020, Clean Sky 2 made some limited efforts seeking better alignment with European Structural and Investment Funds. Results achieved indicate that a better alignment of the R&I efforts between European and national levels could lead to significant efficiency gains.

Some of the most promising technologies to achieve climate neutrality in aviation are the core business of other sectors. The obvious examples are hydrogen and batteries, but also digitalisation could have a significant impact on the environmental performance of the sector.

The insufficient tracking of technological developments in other sectors may lead to aviation being unaware of potentially interesting research or unable to transfer and take up potentially useful technologies developed elsewhere into its own R&I path.

In addition, those other sectors may be unaware of the specificities of aviation (such as limiting weight, be able to function under extreme heat/cold and at altitude, safety) to be taken into account in their own research. It should be carefully analysed how the experience and know-how of these sectors could be translated to aviation.

Responses to the **Open Public Consultation** widely agreed on the nature of the problem drivers. Most of stakeholders agreed strongly that innovation and development cycles in the industry are both too long and too costly and these views were held in similar proportions across all stakeholder groups. Stakeholders also noted the presence of regulatory barriers in the context of standards and disruptive technology development, although these considerations were felt less strongly than those regarding the innovation cycles. A majority of stakeholders also noted that the lack of global integrated standards undermines the benefits of R&I activities developed at an EU level, thus affecting European competitiveness.

Similar views were also emphasised by most **interviewed stakeholders**, particularly supporting the views that the development cycles in the industry are both long and costly, and that regulatory barriers⁹⁰ need to be suitably addressed to not cause further delay to development cycles. There was a strong consensus, in the absence of policy intervention, that it would not be possible to achieve the long-term strategy and level of stakeholder participation required to achieve the goal of climate neutrality by 2050.

2.3. How will the problem(s) evolve?

The lack of a framework to secure the necessary long-term commitments, reduce the financial risks, and combine the R&I capacity in Europe may result in the delay or cancellation of expensive demonstrators or system integration projects based on decades of research at low and later high TRLs which would significantly reduce the impact of R&I in aviation, and delay achieving the green deal targets. The reshuffling of priorities in response to COVID-19 by the European Industry may have an additional negative influence.

Without policy intervention creating such frameworks, the gap between technological progress and the European Green Deal's ambitions will widen, leaving only market based measures such as additional taxes on fuel, expanding the ETS system etc. to achieve the European Green Deal's ambitions and reducing air traffic, with significant negative social and economic consequences, and reducing the competitive lead of the European industry. In this it should be taken into account that technology maturation requires an exponential increase in resources, rather than a linear one, because the more integration towards the final product/system is achieved, the more complexity needs to be addressed. The kind of demonstration and integration, projects needed before moving towards product development are very costly, and risky for the industry involved.

As explained above, without any policy action, it is anticipated that an increased gap will form between the demand for mobility and the achievement of the climate neutrality target.

The Figure below outlines the potential evolution of the problem if there is no intervention. It uses two sets of numbers, the first set based on the EC PRIMES Reference Scenario⁹¹ whilst the second comes from EC estimations⁹². Those forecasts have been produced before the COVID-19 crisis and may be now overestimated. However, aviation will most likely recover at some point and reconnect with the current trends.

Potential evolution of the problems if there is no intervention

Parameter	Position from 2022	Source	Commentary on starting point and evolution during period of Horizon Europe
Air passenger traffic growth	Ranges between +2.2% per annum	EC (PRIMES) EC (Inception)	Different sources of traffic forecasts anticipate different rates of air passenger growth: the EC

⁹⁰ A brief explanation on these perceived regulatory barriers is annexed

⁹¹ The EU Reference Scenario is one of the European Commission's key analysis tools in the areas of energy, transport and climate action. It allows policy-makers to analyse the long-term economic, energy, climate and transport outlook based on the current policy framework.

https://ec.europa.eu/energy/sites/ener/files/documents/20160713%20draft_publication_REF2016_v13.pdf

⁹² https://ec.europa.eu/info/law/better-regulation/initiative/11904/publication/5722372/attachment/090166e5c639d431_en

	to +4.4% per annum	Impact Assessment)	PRIMES Reference scenario estimates that air passenger will grow an average of 2.2% per annum, whilst the EC IIA estimates that it will grow 4.4% per annum. External forces and/or regulation may alter demand for air travel.
Average evolution of fuel consumption per passenger	-1.5% per annum	EC (PRIMES)	Fuel consumption decreased at an average rate of 1.5% per annum. Without intervention, It is assumed that this trend will continue short term. Long term, disruptive new technologies will be required for when the current technologies reach their maximum performance.
CO₂ emissions by 2050 compared to 2020	Ranges between +0.6% per annum to +2.8% per annum (depending on the air traffic forecast source)	Calculated from EC (PRIMES) and EC (Inception Impact Assessment)	The joint impacts of air passenger traffic growth and fuel consumption per passenger results in fuel consumption and emissions rising between 0.6% and 2.8% per annum. Taking the worst-case scenario, CO ₂ emissions will rise by a further 22% during Horizon Europe. If there is no intervention by 2050 this may rise to 137%
Funding of civil aeronautics research and development activities (outside of Clean Sky) by public and private stakeholders	EUR9 billion per annum	ASD	Currently approximately 7% of the civil aeronautics industry turnover is spent on research and development activities. Without intervention, no change is predicted
Years necessary to achieve TRL 1 to 9	Between 10 and 20 years	IATA	No change is predicted. However, a significant acceleration will be necessary to meet the Green Deal requirements and deadlines, for instance by earlier preparation of certification.

Source: Steer analysis

In summary, without policy intervention leading to transformative technology, traffic growth will offset CO₂ emissions reduction resulting in 22% increased consumption of kerosene by 2027. A worst-case extrapolation to 2050, results in a 136% increase in kerosene consumption, compared to 2020.

The European aviation sector will be at greater risk of losing competitiveness in the global market. In turn this could negatively affect investments in research and innovation for greener technologies, which would be detrimental to the achievement of the European Green Deal's objectives.

As the objective of the European Green Deal are global in nature, a slower path towards clean aviation in the EU could also reduce incentives for other manufacturers to develop greener technologies.⁹³ Unless the European Green Deal's targets become, at least de facto, global industry standards.

The continued fragmented R&I capacity of the European aviation value chains will have to develop safe, secure and interoperable aviation solutions.

⁹³ Indeed, upcoming non-EU manufacturers tend to primarily compete on costs and may place less emphasis on greening aviation.

The combined effects will mean that aviation performance will not be consistent with EU climate targets and that the contribution of European aviation to the growth of the economy and employment will be below potential.

The evolution of the problem will also be driven by the overall aviation strategies that will be put in place at the EU level and MS' level, and to a lesser extent at the international level, on the regulatory framework, and the provision of economic incentives or loans.

Stakeholders interviewed tended to support the view that intervention was required in order to bridge the gap between academic based innovations and their commercial application (the ‘valley of death’)⁹⁴, which was more prevalent before Horizon 2020. Stakeholders providing feedback to the inception impact assessment tended to support the view that problems would persist in the absence of policy intervention

3. WHY SHOULD THE EU ACT?

3.1. Subsidiarity: Necessity of EU action

The rationale for EU intervention follows directly from the previous discussion of the problems. The primary justification for EU public intervention in aviation R&I is to harmonise, optimise and coordinate resources at ecosystem level from all European countries towards climate neutrality in aviation – an ambitious target that cannot be achieved by neither one aeronautics company nor single country alone. As underlined above, there is a need for a holistic R&I approach towards climate neutrality.

Furthermore, all research needs should be coherent with market measures, incentives as well as a robust and modern regulatory and standardisation framework, which can only be designed in the EU context and through international cooperation. This framework should be coherent and aligned with environment and climate policies, trade, defence, space, air traffic management, certification and standardisation schemes which are under the remit of the EU.

In addition, European research with open competitive calls allows participants to break away from their natural suppliers and develop new partnerships with different types of organisations (academia, research centres, industry etc.) including those from EU countries without traditional aviation industry but potentially bringing novel approaches.

The rationale for EU intervention includes risk sharing, considering the high costs of developing and demonstrating innovative technological solutions, which cannot be carried out by individual companies alone.

In the context of the specific characteristics of the aviation sector, the costs and risks of new developments depend on effective cooperation at European scale. Cooperation between different stakeholders is important, both in the development stages as well as during the maturing of innovative technologies.

⁹⁴ The ‘Valley of Death’ was referred to in several stakeholder interviews and is a metaphor often used to describe the gap between academic-based innovations and their commercial application in the marketplace.

3.2. Added value of EU action

With a clear climate policy and clear objectives for 2030 and for 2050, there is a strong need for directionality of European investments as well as additionality. EU action would complement the national schemes to provide a clearer policy approach, especially as innovations are urgently needed to realise the climate action plan and objectives.

The European Commission is ideally placed to strive towards cooperation between the national aviation R&I programmes and the Clean Aviation initiative, avoiding duplication of effort and combining resources towards achieving the European Green Deal's targets.

At the same time, it takes the initiative on many aviation related policy measures and can ensure that policy measures, legislation and R&I efforts are aligned.

Further, The European Commission is an ad-hoc observer in many ICAO⁹⁵ bodies (Assembly and other technical bodies) focusing on aviation safety, security, environment, air traffic management and air transportation.

Among stakeholders responding to the **Open Public Consultation** there was widespread recognition of the problem of fragmentation and lack of effective coordination of R&I activity, underpinning the case for intervention at the European level.

Stakeholders participating in the **interviews** and providing feedback on the **inception impact assessment** were also generally fully supportive of EU action to address these and other aspects of the problem. Member States and businesses agreed that the pan-European nature of the industry coupled with uncoordinated support for R&I at national level justified EU action.

4. OBJECTIVES: WHAT IS TO BE ACHIEVED?

4.1. General objectives of the initiative

Based on the identified problems, the initiative's main objective would be to contribute to **reduce the ecological footprint by accelerating the development of climate neutral aviation⁹⁶ technologies for earliest possible deployment, therefore significantly contributing to the achievement of the general goals of the European Green Deal, i.e.: a 50% to 55% emissions reduction by 2030, and climate neutrality by 2050⁹⁷.**

The focus on climate neutrality, in line with the Commission's top priority, is justified because other environmental aspects can be covered by the collaborative research programme (outside the partnership), and because a push towards climate neutrality requires a strong mobilisation of the whole community around the most promising technologies, which is less the case for other environmental aspects.

⁹⁵ https://ec.europa.eu/transport/modes/air/international_aviation/european_community_icao_en

⁹⁶ Clean Aviation is complemented by a collaborative research effort that deals with other aviation research priorities.

⁹⁷ The main objective complements several of the Sustainable Development Goals (SDGs) supported by the Climate, Energy and Mobility Cluster, including SDG 3 (Good Health and Well-being), SDG 9 (Industry, Innovation and Infrastructure), SDG 11 (Sustainable Cities and Communities), SDG 12 (Responsible Consumption and Production) and SDG 13 (Climate Action).

The second general objective would be to ensure that aeronautics-related research and innovation activities **contribute to the global sustainable competitiveness** of EU aviation, while ensuring that remains a safe, secure, reliable, cost-effective, and efficient means of passenger and freight transportation. Without a strong European supply chain, Europe has no leverage to pursue to ambitious environmental policy.

The third objective would be to **further advance the European R&I capacity** to accelerate and optimise the R&I process. This objective is similarly aligned with several SDGs, especially SDG 9 (Industry, Innovation and Infrastructure).

It should be noted that addressing market and regulatory barriers is not in the research remit of any future initiative but remains vital for achieving the general objectives.

There was strong support from stakeholders responding to the open public consultation to making significant contributions towards achieving the EU's climate-related goals. The vast majority of business organisations (both large organisations and SMEs), business associations, academic and research institutions, public authorities and EU citizens considered that any future European Partnership should respond effectively to achieving European policy goals and recognised that this is hindered by development cycles in the industry that were both lengthy and costly. Most of these groups also confirmed the importance of meeting societal needs and contributing to both EU climate related goals and UN Sustainable Development Goals through the effective deployment of new technology, whilst also maintaining European competitiveness in the market.

Stakeholders interviewed, whether from industry, research institutes, academics or other types of organisations were generally very supportive of the proposed objective of achieving climate neutrality by 2050. It was felt that that objective, whilst ambitious, was more encompassing of the effects of aviation and also allowed a more long-term solution to be realised.

Virtually all stakeholders providing feedback on the **inception impact assessment** also noted their support for the previous objective⁹⁸ of achieving deep-decarbonisation in the industry.

4.2. Specific objectives of the initiative

The following specific objectives have been defined for the R&I efforts under the Clean Aviation initiative:

- **to demonstrate disruptive aircraft technological innovations able to decrease net emissions of greenhouse gasses by no less than 30% by 2030, compared to 2020 state-of-the-art technology;**

The primary objective is to achieve climate neutrality by 2050, with an intermediate step towards 2030. Together with the large-scale deployment and use of new, net-zero or fully decarbonised sustainable aviation fuels such as power-to-liquid synthetic fuels, methane and/or hydrogen, the operating fleet in 2050 could achieve a 90+% improvement in carbon efficiency compared to today's fleet. The sector can meet the Air Transport Action Group's (ATAG) goal to halve total CO₂ emissions in 2050 compared to 2005 levels, while maintaining its forecast growth.

⁹⁸ The objective was changed from deep-decarbonisation to climate neutrality after the inception impact assessment was issued.

The Clean Aviation initiative should **focus on disruptive technologies** that also allow the earliest possible deployment with the greatest potential to contribute to the ambitious European Green Deal targets for 2030 and 2050.

Three key R&I ‘thrusts’ will drive the energy efficiency and the emissions reductions of future aircraft.

- **Hybrid electric and full electric architectures** – driving research into novel (hybrid) electrical power architectures and their integration; and maturing technologies towards the demonstration of novel configurations, on-board energy concepts and flight control.
- **Ultra- efficient aircraft architectures** – to address the short, medium and long-range needs with innovative aircraft architectures making use of highly integrated, ultra-efficient thermal propulsion systems and providing disruptive improvements in fuel efficiency. This will be essential for the transition to low/zero emission energy sources (synthetic fuels, non-drop in fuels such as hydrogen), which will be more energy intensive to produce, more expensive, and only available in limited quantities.
- **Disruptive technologies to enable hydrogen- powered aircraft** – to enable aircraft and engines to exploit the potential of hydrogen as a *non-drop-in* alternative *zero carbon fuel*, in particular liquid hydrogen.

Exclusions:

- Other aspects of the aviation sector’s comprehensive decarbonisation strategy (eg incremental improvements in energy efficiency of engines and aircraft design, drop-in sustainable aviation fuels) should be supported by industry’s own R&D budgets, or by national resources. Operational measures, such as optimised green trajectories and air traffic management will also contribute in achieving climate neutrality and may be covered by another initiative following the current SESAR Joint Undertaking.
- Alternative energy sources that gradually complement or replace kerosene play a pivotal role in achieving climate neutrality in aviation. These energy sources include sustainable aviation fuels⁹⁹ (SAF), batteries and hydrogen. SAF are already available on the market and are therefore excluded from the research activities of a Clean Aviation initiative.
- **Ensure the market readiness of innovative, climate neutral, safe and interoperable solutions for aviation**

The second specific objective is to ensure that the technological innovations are available in time to permit the launch of disruptive new products and services by 2035 – with the aim of replacing 75% of the operating fleet by 2050 – and developing an innovative, reliable, safe and cost-effective European aviation system that is able to meet the objective of climate neutrality by 2050.

⁹⁹ Sustainable Aviation Fuel (SAF) is a clean substitute for fossil jet fuels. Rather than being refined from petroleum, SAF is produced from sustainable feedstocks such as waste oils from biological origin, agri residues or non-fossil CO₂

An independent Impact Monitor mechanism should ensure continuous strategic monitoring and steering, and ensure objectives are met.

The continuous assessment of intermediate project deliverables should guarantee that the developed technologies meet their full innovation potential, or allow re-orienting the research and innovation activities towards the most promising technologies.

Modelling, testing, evaluation, and assessment will play a vital role within the clean aviation initiative in validating technologies and increase their change to reach the market:

- To select the most promising technologies with the highest potential to have significant impact on climate change and to assess the impact that the implementation of those technologies on the market would have.
- To evaluate project progress and assess how practical research results confirm the impact forecasts, potentially leading to re-orienting the projects.
- To identify knowledge gaps and shortcomings and define targeted projects to tackle these.
- To support safety certification in cooperation with an independent EASA to mitigate safety concerns and accelerate the research life cycle and the introduction of technologies in the market later on.

Thorough testing and demonstration (in-flight) of new technologies should guarantee that they are sufficiently matured, reliable and affordable to be integrated in novel aircraft designs and ensure that they are taken up by the market.

The impact monitor could play a role in preparing for international standards and certification of novel technologies.

- **To expand and foster integration of the aviation research and innovations value chains, including academia, research organisations, industry, and small and medium sized enterprises, also by exploiting synergies with other, related, national and European programmes**

The independent Impact Monitor will be used to support dialogue with internal and external counterparts regarding environmental aspects, policies, required infrastructures and critical success factors for the transition to a climate neutral aviation. The Impact Monitor mechanism could also be used to assess other parts of Horizon Europe relevant to the partnership, such as traditional calls.

Building upon the work done under Clean Sky 2, the initiative will increase efforts to exploit synergies with other initiatives and programmes with a special focus on areas offering a high potential such as hydrogen, batteries and digital that could bring new knowledge to the aviation sector.

Discussions on the best mechanisms for exploiting synergies with other partnerships, or with collaborative research in aviation are still on-going.

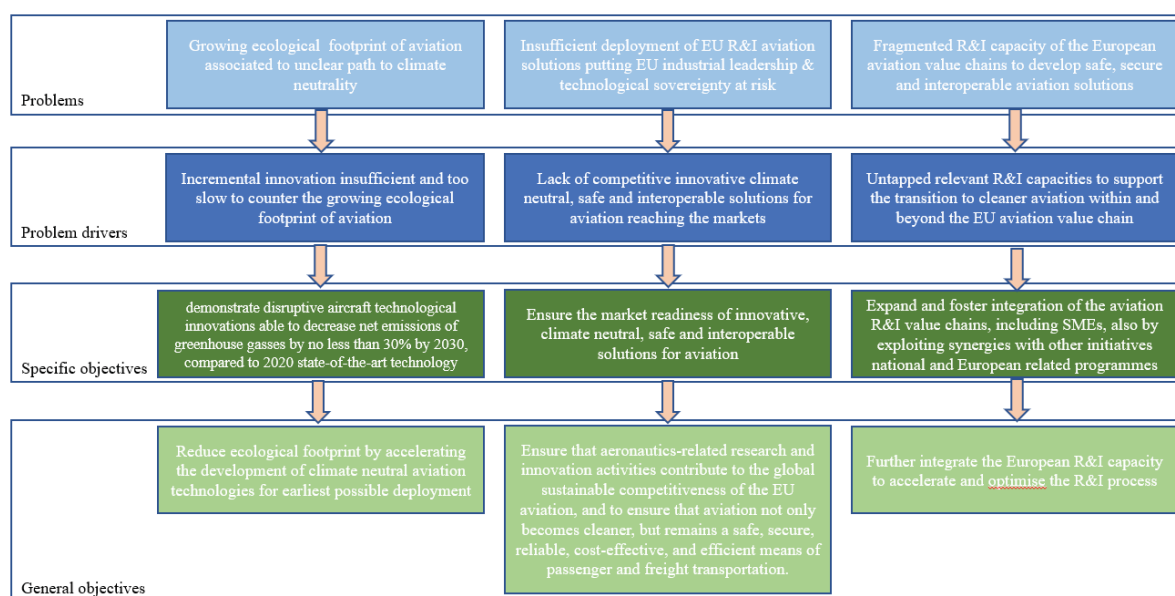

Respondents to the open public consultation – including business organisations of different sizes, business associations, academic and research institutions, public authorities, and EU citizens – largely endorsed the view that a European Partnership

should be responsive to societal needs and should make a significant contribution to achieving the UN SDGs and EU climate-related goals. The vast majority also agreed that more focus should be placed on bringing about a transformative change towards sustainability through the development and effective deployment of technology, whilst also making significant contributions towards EU global competitiveness.

Stakeholders interviewed supported to focus higher proportions of the budget on larger aircraft, as resultant developments have larger impacts versus other aircraft. All stakeholders interviewed supported the inclusion of regulators throughout the development process, albeit in an observational capacity, to assist in addressing market barriers to entry.

Stakeholders providing feedback to the **inception impact assessment** were generally very supportive of the objectives identified in the document, in particular the need to explore, mature and demonstrate new technologies, whilst also ensuring competitiveness of the European aeronautics industry.

4.3. Intervention logic for the initiative

How would success look like?

Should the initiative deliver on its specific objectives, it is expected that it would translate in practice into the following impacts:

Expected Scientific impacts

- Acceleration of the development of know-how and the process of maturing technologies and knowledge transfer for key new technologies and ‘differentiators’;
 - Increased ability to theoretically model and compute the effects of new technologies.
 - Increased scientific knowledge of climate impact and atmospheric effects and so enable optimised interventions in the aviation system.
- Increased diffusion of scientific excellence and high-quality knowledge in the field of aeronautics among research staff from universities, research institutes or private companies;
 - New high-value skills and new engineering capacities for future generations of the European workforce.

- Increased collaboration with other sectors and integration of areas of fundamental research that are not traditionally within the aeronautical scientific ecosystem;
- Strengthened innovation pipeline by creating better directionality of research;

All academic and research institutions responding to the **open public consultation** were highly in favour of the potential partnership being used for the advancement of science. This was supported by most businesses and other stakeholder groups too. The views on its role in development of new scientific knowledge and capabilities were similarly highly positive among all stakeholder groups.

Similar opinions were expressed by stakeholders engaging in the **interviews**, particularly academic and research institutions. During these interviews many academic and research institutions mentioned that more research resulting from the partnership should be published.

Stakeholders responding to the **inception impact assessment** were generally supportive as well of the view that an initiative under Horizon Europe would have important scientific impacts.

Expected economic/ technological impacts

If successful, the proposed initiative has the potential to achieve direct and indirect economic and technological impacts affecting several areas of the EU economy and society, namely:

Direct impact

- New safe, climate neutral and efficient airborne transport modes such as regional aircraft that have the potential to reduce traffic congestion in highly populated areas, and connect remote regions;
- Increased competitiveness of European aeronautics industry through cost-efficiency improvements throughout the entire supply-chain;
 - This would also be a catalyst for a further reduction in environmental impacts. Together, these impacts would contribute to the achievement of SDG 11 (Sustainable Cities and Communities) and SDG 13 (Climate Action);
 - Growth in aviation industry and wider employment;
- New sustainable business models for innovative aircraft technology for future aircraft and fleet retrofits, exploiting next generation digitalisation/automation technologies;
- The emergence of new branches of the aviation industry, such as new sources of propulsion, systems or airframes which will enhance European competitiveness.
 - Strategic partnerships with non-aviation sectors to make use of emerging technologies (e.g. drop-in and non-drop-in fuels, fuel cells, batteries, artificial intelligence, electronics, and materials).

Indirect impact

- A multitude of spin-offs that will benefit Europeans through exploitation of critical areas such as disaster response, emergency interventions, space and security;
- International co-operation prowess, leadership and shared socio-cultural values.
- Strengthened demand for sustainable forms of energy for aviation;
- Increased demand and opportunity for sustainable air mobility leading to job creation;

Most stakeholders consulted as part of the **open public consultation** scored the resulting economic and technological impacts from the partnership as being very relevant. The following impacts received high relevance scores: increased industrial leadership and uptake of new technologies; the acceleration of key technologies through selected demonstrators; as well as the creation of high-skilled jobs in the low-carbon economy.

In addition to supporting above views, several **interviewed stakeholders** highlighted the importance of encouraging participation from a wide group of stakeholders, including those outside the traditional aviation industry, to assist with the development of innovative technologies. As mentioned previously, there was a consensus that regulatory bodies (such as EASA) should also have early knowledge of all developments to ensure that the regulation process did not ultimately delay the introduction of new technologies.

Stakeholders responding to the **inception impact assessment** generally confirmed that an initiative under Horizon Europe could be expected to deliver substantial economic and technological benefits, whilst ensuring competitiveness of the European aeronautics industry.

Expected societal impacts

- Clean Aviation will significantly contribute to the delivery of Europe's climate neutrality by 2050 by pioneering new solutions in the aeronautics disciplines and readying them for market introduction.
 - Considerable impact on reducing climate change, considering that the European aeronautics industry is a world leader in the field and produces +/- 50% of all civil aircraft (SDG 13 Climate Action).
 - Reduction of noise and improved air quality around airports with positive and immediate impact on the health of citizens in support of SDG 11 (Sustainable Cities and Communities).
 - Positive impact on the health and well-being of EU citizens, starting with those living in the vicinity of airports (pollution and noise reduction) as well as for other part of the world. SDG 3 (Health and Well Being)
- Further increase safety and security levels, in cooperation with the European Union Aviation Safety Agency (EASA) by deeply transforming present operations with the help of innovation;
- Fulfil customers' and the general public's expectations of a globally competitive European industry;
- Improving mobility and connectivity of European citizens with safe, reliable, affordable and resilient air travel options.

The majority of the respondents to the **open public consultation** have mentioned the importance of societal benefits and view the reduction in CO₂ emissions and the improvement in public health as being particularly relevant impacts associated with the future partnership.

The vast majority of **interviewees** maintained the view that safety in European aviation was of paramount importance, but also mentioned that developments from new technologies would ensure the longevity and relevance of the European aeronautics industry, whilst also resulting in reductions of gas and noise emissions, which in turn would contribute to improved societal impacts.

4.4. What is needed to achieve these objectives – Key Functionalities needed

Given the focus of the impact assessment on comparing different forms of implementation, the identification of “key functionalities needed” allows making the transition between the definition of the objectives and what would be crucial to achieve them in terms of implementation. These functionalities relate to the type and composition of actors that have to be involved, the type of range of activities that should be performed, the degree of directionality needed and the linkages needed with the external environment.

4.4.1. *Type and composition of the actors to be involved*¹⁰⁰

The inclusion¹⁰¹ of the largest possible number of stakeholders from across the value chain, from different sectors, backgrounds and disciplines, and EU Member States is essential for an initiative for Clean Aviation research and innovation to leverage all the relevant expertise and capabilities. In particular:

The European industry, including SMEs, to develop and ensure the uptake of the most promising climate neutral solutions.

Academic and research organisations to translate disruptive ideas, possibly coming from other sectors, to the aviation context.

The Commission and Member States to ensure alignment and synergies between the EU, national and regional priorities and funding programmes and for a broader political coordination of national and international policies to achieve impact.

An increased involvement of **Member States** in the deployment and uptake of the most promising climate neutral technologies at EU level will promote synergies and economy of scale with the national R&I programmes as well as increase the alignment of the national educational schemes to match the future needs for corresponding skills and jobs.

EASA to provide guidance on certification related matters, and in assessing the environmental impact of the proposed solutions.

The broader stakeholder community (e.g. airports) that will ultimately roll-out and implement the new aircraft at an early stage should allow anticipating practical considerations such as needed infrastructural works from an early stage.

Note: International participation should be considered in compliance with the Horizon Europe rules for associating countries to the Horizon Europe.

The Figure below summarises the stakeholders that need to be involved and indicates the capabilities that they can bring.

Type and composition of actors that need to be involved

¹⁰⁰ This functionality relates to the criterion “Involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness”.

¹⁰¹ Annex 6.9 shows the high interest of stakeholders from various backgrounds (industry, SME, academia, research organisations) for participating in the Clean Aviation initiative.

	Aeronautics Industry	Universities and research institutions	Member States	End-users (Airline and airports)	EASA	Technology-based organisations outside aviation
Long term perspective	✓	✓	✓	✓	✓	✓
Flexibility and disruptive thinking	✓	✓				✓
Expertise in aircraft operations		(✓)		✓	✓	
Understanding of passengers, aviation workers and citizens needs			✓	✓	✓	
Understanding of current R&I	✓	✓	✓			✓
In-kind support	✓	✓			✓	✓
Financial contribution	✓		(✓)			✓

4.4.2. *Type and range of activities needed*

Given the very ambitious objectives, a **strategic vision** for the initiative is essential for the prioritisation and focus. It is important that the initiative sets out and maintains (reality checks) a comprehensive strategic research and innovation agenda including milestones and deliverables.

Increased focus on the most promising breakthrough technologies and a limited set of high TRL (4 to 6+), integration, demonstration and validation demonstrators. These high TRL activities may be supported on a case-by-case basis with limited low TRL (1-3) research activities that are directly linked to the demonstrators.

Increased **openness and transparency** through open calls and actively seeking for potential partners from outside the traditional aviation sector.

Reinforced **public involvement** in the governance of the initiative should avoid a tendency within the private sector for a ‘share the cake’ approach instead of a real strategic orientation towards higher performance and lower climate footprint. This includes a feedback to relevant policy initiatives.

Enhanced governance responsibility for the demonstrator and project progress.

Independent monitoring, progress and impact assessment directly reporting to the governing board. These assessments will also contain aspects related to the post-research stage, in verifying the feasibility of bringing technologies to the market considering the unequivocal deadlines (2030 and 2050) set out in the European Green Deal.

Actively **exploiting synergies** and coordination of R&I activities, especially with the proposed air-traffic management partnership under Horizon Europe (the current SESAR Joint Undertaking).

4.4.3. *Priority setting system and level of directionality required*

A common vision and a Strategic Research and Innovation Agenda is under development, taking into consideration the diverging business agendas and the post-covid-19 aviation crisis. To address the future challenges, Horizon Europe proposes a holistic approach that is based on two main sets of activities.

Firstly, a Clean Aviation initiative that will focus on the acceleration of the development, validation and integration of climate-neutral technologies, towards market uptake and with strong long-term commitment of industry but also academia and research organisations.

A Strategic Research and Innovation Agenda (SRIA) will focus on the activities foreseen in the context of the Clean Aviation initiative. The programme and its content will be clearly described and ring-fenced. Links to, and expected inputs from other research programmes (other partnerships, collaborative research or otherwise) shall be indicated in a summarised form for later elaboration and a close coordination between Clean Aviation, the Commission and these other areas/partnerships is envisaged.

Exclusions:

- Sustainable aviation fuels research is outside the scope of the Clean Aviation initiative (as it is dealt with in the energy-related partnerships, missions and other instruments). However, technological development needed for their use is within the scope. Technical and system level impacts for drop-in can be justified if an essential element of the demonstrator logic. Technology development and initial demonstration efforts for non-drop-in, notably liquid hydrogen, are in scope and of interest.
- Low-TRL research generally are out of the scope of the Clean Aviation initiative unless it concerns the accelerated development of essential low-TRL activities which are directly linked to development, integration and validation of the demonstrator elements and/or their future transition to a market offering.
- Critical enablers i.e. technologies that would lead to essential features of the demonstrator in terms of its successful transition to a viable product can be in scope if motivated properly.

Secondly, collaborative research will bring together all stakeholders, but primarily research establishments, academia and SMEs will mature low-TRL technologies (including climate neutral ones) which could benefit from subsequent acceleration and deployment in the second fifteen-year cycle.

- The bulk of low-TRL aviation research needs an adequate collaborative research programme in Cluster 5. Low-TRL R&I in the collaborative part of Cluster 5 of Horizon Europe will complement the Clean Aviation initiative's SRIA.
- A strong and effective mechanism will be developed together with the Commission for the effective and efficient transfer of knowledge and research outcomes in areas of relevance to the Clean Aviation initiative, and to enhance exploitation through the

absorption in the demonstration programme areas within the Clean Aviation initiative.

- The Commission, through its presence in both the Clean Aviation initiative and in defining the work programmes for collaborative research, will ensure the complementarity between both.

A key added-value of Horizon Europe will be the increased synergies between EU, national and regional levels and the timely development of transformative and disruptive climate neutral aviation pathways. Lessons learned from the current Clean Sky 2 programme include:

- The European strategic R&I agenda needs to be well-focused and designate a few disruptive research paths, since targets cannot be achieved with purely evolutionary paths as it was in the two Clean Sky programmes;
- stronger synergies as well as coherent and timely alignment with national/regional R&I programs;
- better planning and better connection to Pillars I and III of Horizon Europe, as well as other relevant partnerships.

Public oversight, and regular reviews of projects, should ensure that focus on the green deal ambitions is not lost in favour of less disruptive approaches that could fit better the research and commercial agenda of the industry. This entails political commitment from both Member States' and the Commission to ensure that the work (such as infrastructure) needed to support the new technologies on the market is done.

4.4.4. Coherence needed with the external environment

Issues related to the policy, regulatory and financial inadequacies framework have to be addressed in parallel and/or factored in so that the initiative is enabled to achieve its objectives and effectively contribute to the climate policies and targets from a broader perspective. This could be addressed by future developments of the regulatory framework and aviation relevant policies and strategies.

Achieving climate neutrality will partly depend on adopting and integrating new, environmentally friendly energy sources such as sustainable aviation fuels, electricity (batteries) or hydrogen. Links to relevant R&I partnerships and programmes active in these areas will be very important.

The European Commission and Member States should ensure better synergies between the EU, national and regional funding programmes to allocate sufficient resources to the ambitious Clean Aviation projects.

In addition, ties with the broader policy initiatives is crucial to support the achievement of the objectives of an initiative on Clean Aviation by facilitating market uptake.

This could include building upon other European programmes such as:

- European Investment Bank (EIB) loans¹⁰²: EIB loans and guarantees may provide funding for relevant market uptake of projects. One of the current priorities of the EIB is

¹⁰²<https://www.eib.org/en/press/all/2019-313-cu-bank-launches-ambitious-new-climate-strategy-and-energy-lending-policy>

climate and environment, including sustainable transport. Additional support should be in line with WTO rules.

- Cohesion Policy Funds: includes the European Regional Development Fund (ERDF) and Cohesion Fund (CF), which aim to increase economic and social cohesion and reduce imbalances and disparities between the regions of the European Union, may also provide support, including indirect, the further development of the aeronautics industry in certain Member States.
- Connecting Europe Facility¹⁰³ (CEF): CEF is an EU funding instrument to promote growth, jobs and competitiveness via targeted infrastructure investment at EU level. It is important for encouraging the deployment of these technologies, in particular airports' fuel/ electrification infrastructure, and green door-to-door air transports corridors.
- As well as building upon national and regional funding such as the French research national programme (CORAC), as well as the German federal aeronautical research programme *Luftfahrtforschungsprogramm* (LuFo) underlining the need to an increased involvement of Member States in the aviation partnership.

The impact on airport and air traffic management infrastructure and operations will also need to be considered, as new aircraft technologies may result in new operational requirements for airlines, airports, and air traffic management providers.

5. WHAT ARE THE AVAILABLE POLICY OPTIONS?

This section describes the specific functionalities that could be provided under the baseline scenario of traditional calls and the different options of different types of European partnerships.

5.1. What is the baseline from which options are assessed

The baseline scenario used in this impact assessment is a situation without a Partnership and only traditional calls of Horizon Europe. Given that there is a predecessor Joint Undertaking as well as other funding sources in the area, these will continue generating effects even if there is no new Partnership. In particular it is expected that these already existing initiatives will still create effects on maturing technologies addressing environmental concerns up to TRL 6. This is taken into account in the effectiveness assessment.

In parallel, the baseline situation means that the current implementation structure of the Article 187 would be closed, which bears winding down and social discontinuation costs. There would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is taken into account in the efficiency assessment.

Table 1: Key characteristics of the baseline situation - Horizon Europe calls

	What is feasible under this option - Functionalities of option
--	--

¹⁰³ https://ec.europa.eu/transport/modes/air/airports_en

<p>Enabling appropriate profile of participation</p>	<ul style="list-style-type: none"> • The Commission would need to prepare the Strategic Research and Innovation Agenda (SRIA) by consulting a wide range of actors covering the complete aeronautics value and supply chain, and in addition consult key associations such as ACARE, ASD and so on, as well as the broader aviation community (airports, airlines ...) possibly through their federations. • A well-defined process would be needed to ensure that the programme committees of Member States/ Associated Countries were properly informed about R&I priorities, including key demonstration programmes. • The specification of calls over the period of the Framework Programme could reflect the need for an evolving profile of participation, with different consortia forming at different stages to take different types of activity forward.
<p>Supporting implementation of R&I agenda</p>	<ul style="list-style-type: none"> • Implementation would rely on standard infrastructure underpinning the open calls procedure, drawing on resources of relevant Commission Executive Agencies and systems, benefiting from economies of scale. • Administrative costs for the European Commission would be significantly reduced. • Calls for proposals would be published in the work programmes of Horizon Europe. • Transparency and open publication of results would ensure their availability to interested parties. • Dissemination of knowledge and share of practice would happen predominantly among partners within the calls consortia.
<p>Ensuring alignment with R&I agenda</p>	<ul style="list-style-type: none"> • Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from representatives of all relevant stakeholders. • Specification of calls for activity at higher TRLs, particularly demonstration programmes, would need input from industry. • Calls would need to be compatible with CS 2 Joint Undertaking ITDs/ IATD¹⁰⁴ to ensure continuity where appropriate • R&I activity would focus on the short to medium term needs of the industry. • Commission input into specification and oversight of calls would help to ensure alignment with overarching policy objectives but integration with other programmes would require additional coordination. • Selection of high TRL projects would require provision of external expert (and independent) advice to the Commission (as has been done in the past in FP5, FP6, etc.)
<p>Securing effective leveraging of resources</p>	<ul style="list-style-type: none"> • Progress of R&I effort would depend largely on EU funding, with no mechanisms to ensure binding industry commitment and additional contributions. However, depending on the R&I scope and co-financing rules, some contributions from industry support could be expected at project level. • Demonstration programmes would require significant in-kind support and collaboration from industry, but there are some unknowns as to whether critical mass could be reached.
<p>Key differences compared to the current situation</p>	<ul style="list-style-type: none"> • The programme and project management tasks performed by the JU should be performed elsewhere and a separate Technology Evaluator and impact assessment mechanism has to be defined. • Portfolio of individual projects with reduced strategic integration and demonstration leading to less maturation of the technologies. • Potentially very promising Clean Sy 2 outcomes would not find a habitat to be further developed. • Clean Sky 2 knowledge and experience pool disappears, and is not further exploited.

5.2. Option 1 - Co-programmed European Partnership

Table 2: Key characteristics of Option 2 – Co-Programmed European Partnership

¹⁰⁴ ITD: Integrated Technology Demonstrator. IADP: Innovative Aircraft Demonstrator Platform

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation	<ul style="list-style-type: none"> • The partnership would enable participation by key stakeholders as partners – to commit and contribute to the specification and delivery of the common strategic R&I agenda. • The strategic R&I agenda is developed prior to the partnership to ensure that partners know what they sign up to and the wider community is aware of the ambitions. • It would need to consult with a wide range of stakeholders to ensure that the R&I agenda, and ultimately the work programme, was aligned with industry and market needs. • At the same time, it would offer the flexibility to change the profile of participation over time, with new partners joining to support new areas of activity in response to emerging results and changing priorities.
Supporting implementation of R&I agenda	<ul style="list-style-type: none"> • Implementation would rely on standard administrative infrastructure underpinning the open calls procedure, drawing on resources of relevant Commission executive agencies and IT systems. • Calls for proposals would be published in the work programmes of Horizon Europe. • Transparency and open publication of results would ensure their availability to interested parties. • Partners are responsible for drafting input to the work programmes, and for implementing their additional activities, notably to support the take-up of results (these are agreed in the SRIA and annual work programmes)
Ensuring alignment with R&I agenda	<ul style="list-style-type: none"> • Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from the various partners to achieve an appropriate balance of activity directed towards different markets. • The partnership would be responsible for ensuring that priorities for calls were specified in line with R&I priorities, including demonstration programmes. • Specification of calls would need to be informed by CS2 JU ITDs/IATDs to ensure continuity where appropriate • R&I activity would be likely to focus on the medium to long-term needs of the industry. • Commission co-steering role and Programme Committee responsible for mobility would need to ensure alignment with overarching policy objectives and coordination with related programmes.
Securing effective leveraging of resources	<p>Aspirations for partner contributions would be clearly defined at the outset. Commitments from partners would be defined at the outset, with private sector partners expected to match at least half of partnership resources through in-kind contributions.</p> <p>Industry commitments would be best efforts, defined in the contractual arrangement. Expected in-kind contributions from the private sector would be identified in the work programme.</p>

5.3. Option 2 – Institutionalised European Partnership

Table 3: Key characteristics of Option 2 – Institutionalised European Partnership (Article 187 TFEU)

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation	<ul style="list-style-type: none"> • The partnership would enable participation of key stakeholders as partners – to commit and contribute to the specification and delivery of the SRIA. • The strategic R&I agenda is developed prior to the partnership to ensure that partners know what they sign up to. • The implementation of the agenda would not need further consultation, as the structure, thanks to its technical, economical and industrial knowledge and acquired expertise, allows self-management.

	What is feasible under this option - Functionalities of option
	<ul style="list-style-type: none"> • It would provide a forum or even a platform for consulting stakeholders on R&I priorities and the work programme, ensuring that they are aligned with industry, research and market needs and with the agenda of other partnerships and sectoral programmes. • Participation would be less flexible than under other options, but it might nevertheless be possible to change the profile of participation over time, with new partners joining to support new areas of activity in response to emerging challenges and evolving priorities.
Supporting implementation of R&I agenda	<ul style="list-style-type: none"> • A dedicated administrative structure would be established to coordinate the specification of R&I activity, manage implementation and report on the results (with administrative expenditure limited to 4% of the budget and subject to an indicative 40:60 allocation between the Commission and private partners). • Dissemination of knowledge and share of practices would happen among the stakeholders of the community, and through additional diffusion activities managed by the partnership structure. • Calls for proposals would be published broadly by the administrative structure. • Transparency and open publication of results would ensure their availability to interested parties.
Ensuring alignment with R&I agenda	<ul style="list-style-type: none"> • The partnership would be responsible for specifying a work programme fully in line with the R&I priorities identified by the industry to fulfil the European policy needs. • The work programme would reflect the medium- and long-term needs of industry, the research organisations and society in adopting clean aviation solutions. • The work programme can build on, but not be constrained by, the current CS 2 JU ITDs/IADPs to ensure continuity where appropriate. • Commission participation in the partnership governance arrangements and approval of the work programme would help to ensure alignment with overarching policy objectives and enable integration with other programmes.
Securing effective leveraging of resources	<ul style="list-style-type: none"> • Funding requirements would be clearly defined at the outset, with private sector partners required to provide between 50% and up to 75% of partnership resources through in-kind and/or financial commitments. • Given more limited funding than in the past, critical R&I priorities would need to be identified at the outset.

5.4. Options discarded at an early stage

For an initiative on Clean Aviation, industry involvement is vital to ensure that research results are further developed and reach the market as fast as possible. This requires an alignment of the Clean Aviation research agenda and the substantial research budgets of major market participants such as Airbus¹⁰⁵, Rolls-Royce¹⁰⁶, and SAFRAN¹⁰⁷ that spend respectively EUR 3.2 billion, EUR 1.5 billion, and EUR 1.1 billion annually on research and product development¹⁰⁸.

Partnerships, created under Article 185 of the TFEU, do not include private partners, only Member States. A co-funded partnership relies on public bodies with research funders (or governmental research organisations) and other public organisations at the core of the

¹⁰⁵ https://annualreport.airbus.com/pdf/Complete_Annual_Report.pdf

¹⁰⁶ <https://www.rolls-royce.com/investors/annual-report-2016.aspx#group-at-a-glance>

¹⁰⁷ <https://www.safran-group.com/media/safran-2016-annual-results-20170224>

¹⁰⁸ Note that these figures include product development beyond TRL6

consortium. Co-funded partnerships rely on pooling and/ or coordinating national programmes and policies with EU policies and investments. Member States become the ‘owners’ of the priorities and take sole responsibility for its funding. The industry R&I can only be addressed without formal commitments and financial contributions.

For these reasons, these two options have been discarded at an early stage and are not considered suitable for a Clean Aviation initiative where a public-private cooperation is vital to achieving the intended objectives.

6. HOW DO THE DIFFERENT POLICY OPTIONS COMPARE

Based on the objectives pursued by the initiative and the key functionalities identified to be able to achieve them, each option for implementation is assessed in terms of effectiveness, efficiency and coherence compared to the baseline scenario of traditional calls. The analysis is primarily based on the degree to which the different options would cater for the key needed functionalities. All options are compared to the baseline situation of traditional calls, which is thus consistently scored 0 to serve as reference point.

6.1. Effectiveness

To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ – what success would look like – differentiating between scientific, economic/ technological, and societal (including environmental) impacts. This section considers to which extent the different policy options would allow delivering these expected impacts – confronting what is needed (functionalities) with what each form of implementation can provide in practice.

Scientific impacts

The **baseline option** could easily manage fundamental R&I activities (and could be complementary to any type of partnership). It is more directed towards low TRL and academic research and is of less interest to industry players who focus on closer to market research.

It is however unlikely to contribute to the emergence of high TRL solutions and close to market integrated demonstrators that require large scale integration and a coordinated research effort involving many partners and combining the research results of many projects.

This option does not provide for a framework or ecosystem of actors. However, this option could deliver improvements for low and medium TRL applications by a large number of individual small projects if a clear work programme is established.

Option 1 could deliver more impact than the baseline option when it comes to higher TRL applications, where a strong community with all actors is needed in order for all potential partners to liaise on complex projects. It would therefore have a similar or good potential compared to the baseline with scores between 0 and + according to the different types of scientific impacts.

Its better structure would facilitate knowledge exchange between the academic and industrial world.

Option 2 is the most effective option for well-focused integration, demonstration and validation activities in aviation. This option should be complemented with additional collaborative research under Cluster 5, which will bring together all stakeholders, but primarily research establishments, academia and SMEs towards inventing and maturing low-TRL technologies (including climate neutral ones). The management structure can adapt and coordinate the programme orientation based on early individual research results. Its score would therefore be a high potential compared to the baseline with ++ on this aspect.

Economic/ technological impacts

The **baseline option** could contribute to achieve technological impacts but on a very long-term scale, following the current very long life cycle in aviation research. The lack of a community structure beyond the project consortia might limit the sharing and diffusion of experience among the key actors involved and thus limit the coordination and collaboration necessary to integrate the research outcomes.

This option will not significantly support the scaling up of ready-to-market applications as there is no mechanism to facilitate bridging from R&D to market deployment and it is assessed as more difficult for SMEs to access funding. Hence, it will have little impact on the development of new climate neutral transport modes or on creating, on the competitiveness of the industry or on creating new branches of that industry.

This option would probably be less efficient in creating new networks, or to align European, national and company research programmes. In addition, it may not achieve involving the larger aviation community in preparation of market uptake, or in defining priorities for a strategic research and innovation agenda.

Option 1 has a better impact as it provides elements of the governance structure, but does not yet offer the complete governance and management structure required to build large scale demonstrators. Its potential would therefore be between similar and good compared to the baseline (scores of 0/+).

In light of the above, **Option 2** appears as the most effective, provided a concrete commitment from industry not only to develop climate neutral technologies, but also to ensure that the most promising climate neutral solutions would subsequently benefit from a market uptake.

A strategic research and innovation agenda (SRIA) with a clear view on certification needs and implementation measures will be an essential part of the establishment of the Clean Aviation partnership.

A call of expression of interest under the forthcoming research and innovation programme would help identifying the few building blocks where this acceleration of the most promising climate neutral solutions and deployment should be concentrated under the future Partnership.

The future initiative shall have improved, simplified and well performing governance and monitoring capability able to swiftly re-orient the programme where needed. Option 2 would thus be scored as high compared to the baseline with ++.

Societal (including environmental) impacts

The **baseline option**, given the short-term perspective of the calls, and the focus on low TRL research without much attention for technology integration and demonstration, would mainly lead to individual technology improvements. This conflicts with the sense of urgency introduced by the Green Deal that requires a focus on demonstrating integrated solutions close to market and reach concrete impacts by already 2030. Compared to the usual very long development cycles in aviation this is a very short period.

While **option 1** offers some improvements (Scores 0/+) it will require the binding commitments that would be made by the industry in the **Option 2** to enable higher level of market-focused development and demonstration projects and hence a substantially higher level of market take-up, which is essential for meeting the requirements of the European Green Deal.

It would however miss the advanced programme and project management oversight offered by an institutionalised partnership office, making it much more difficult to ensure the correct level of involvement of EASA, and the early detection of risks and issues with projects and demonstrators. This would lead to a loss of effectiveness, and a risk for loss of focus on the most promising technologies and demonstrators. This would inevitably lead to a reduced capacity to reach the green deal climate targets by the deadlines set and would not fulfil the expectations of society.

Option 2 appears to be the only option focussing on the demonstration of the most promising climate neutral technologies with a concrete view (and industry commitment) on their further development into products on the market. Safety would be ensured by involving EASA in the initiative. This would have the envisaged impact on climate neutrality and improvement of citizens' health the initiative aims at.

As demonstrated by the CS and CS2 experience, and recognised in the CS2 mid-term evaluation, Option 2 benefits strongly from its Programme Office that coordinates and executes a very large range of tasks for which ad-hoc and case by case solutions would have to be found under Option 1. This leads to significant gains in effectiveness.

Option 2 is thus scored as having a high potential compared to the baseline with scores of ++.

The capacity to reduce emissions and achieve climate neutrality within the time limits set is directly dependent on the ability to accelerate the integration and demonstration of innovative technologies which requires an advanced programme management.

Table 5: Overview of the options' effectiveness compared to the baseline

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Institutionalised Article 187 TFEU
Scientific impact			
Acceleration of the development of know-how and the process of maturing technologies and knowledge transfer for key new technologies and 'differentiators'	0	+	++
Increased diffusion of scientific excellence and high-quality knowledge in the field of aeronautics among research staff from universities, research institutes or private companies	0	+	+
Increased collaboration with other sectors and integration of areas of fundamental research that are not traditionally within the aeronautical scientific ecosystem	0	+	++

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Institutionalised Article 187 TFEU
Strengthened innovation pipeline by creating better directionality of research;	0	+	++
Economic/technological impact			
New safe, climate neutral and efficient airborne transport modes such as commuter/regional aircraft that have the potential to reduce traffic congestion in highly populated areas, and connect remote regions	0	+	++
Increased competitiveness of European aeronautics industry through cost-efficiency improvements throughout the entire supply-chain	0	0	++
New sustainable business models for innovative aircraft technology for future aircraft and fleet retrofits, exploiting next generation digitalisation/automation technologies	0	0	++
The emergence of new branches of the aviation industry, such as new sources of propulsion, systems or airframes which will enhance European competitiveness	0	0	++
Societal impact			
Clean Aviation will significantly contribute to the delivery of Europe's climate neutrality by 2050 by pioneering new solutions in the aeronautics disciplines and readying them for market introduction.	0	+	++
Further increase safety and security levels, in cooperation with the European Union Aviation Safety Agency (EASA) by deeply transforming present operations with the help of innovation;	0	+	++
Fulfil customer and general public expectations of a globally competitive European industry	0	0	++
Improving mobility and connectivity of European citizens with safe, reliable, affordable and resilient air travel options	0	0	++

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.2. Efficiency

In order to compare the policy options consistently in terms of their efficiency, a standard cost model was developed for the external study supporting the impact assessment for the set of candidate Institutionalised Partnerships. The model and the underlying assumptions and analyses are set out in the Common Part of this Impact Assessment, Section 2.3.2 and in the methodology, in Annex 4. A dedicated Annex 3 also provides more information on who is affected and how by this specific initiative in line with the Better Regulation framework. The scores related to the costs set out in this context allow for a “value for money” analysis (cost-effectiveness) in the final scorecard analysis in Section 6.4.

In addition, for this specific initiative under the baseline scenario of traditional calls, there would be winding down and social discontinuation costs for the existing implementation structure of the current Article 187 initiative.

There would also be longer term financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. These can be estimated at EUR 6 million per year of operation. Overall, it is estimated that the overall longer term cost savings from using traditional calls instead of an Article 187 initiative would exceed the costs incurred for winding down operations. This overall situation is set as the starting point for the comparison of options. The score of this baseline scenario (traditional Horizon Europe calls) is set to 0 to be used as a reference point.

On this basis, the scores for the costs of the different options range from a value of 0, in case an option does not entail any additional costs compared to the baseline, to a score of (-) when an option introduces limited additional costs when compared to the baseline and a score of (-)(-) when substantial additional costs are expected in comparison with the baseline. In case the scores are lower than for the baseline scenario, (+) and (+) (+) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. Indeed, in terms of cost-efficiency, the Co-Programmed Partnership (Option 1) is 2 percentage points more efficient than the baseline and an Article 187 Partnership is 2 percentage points less cost-efficient than the baseline. However, it should be taken into account that winding down the existing Joint Undertaking would have a negative impact on the finalisation of the research agenda of the CS2 programme with key staff leaving before programme finalisation. The objective of the CS2 research programme have a strong link with the European Green Deal's objectives of Clean Aviation independent of the implementation options chosen for the proposed future initiative.

A score of 0 is therefore assigned for **cost-efficiency** to the Co-Programmed options and a score of (-) for the Institutionalised Partnership policy option¹⁰⁹.

Looking at cost-efficiency on the broader perspective of attracting higher level of investments from stakeholders, Option 2 may appear much more cost-efficient. The reason is a much higher total investment in European R&I by the private partners and a more concrete spin-off towards full product development by those private partners leading to new products on the market. This also ensures contribution of the initiative to the Green Deal.

In comparison with CS2, the administrative cost (hence the maximum saving possible when not taking this option) is limited to EUR 80 million compared to a total managed research budget of EUR 4 billion (including additional activities).

Looking at cost-efficiency within context of the effectiveness of achieving meaningful research results with the highest (and fastest) possible value for society and contribute timely to achieving the European Green Deal it should be noted that option 2 scores much higher than any other option.

Although difficult to quantify, a slight loss in effectiveness by choosing option 0 or 1 would lead to much higher costs, and more importantly reduced impact, than potential savings.

In addition, only Option 2 contains all the characteristics as regards partner composition, commitment, governance needed to manage a hugely complex and large research and innovation agenda on time.

Matrix on 'overall costs' and 'adjusted cost scoring'

¹⁰⁹ The baseline (traditional calls) is scored 0, as explained above.

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Administrative, operational and coordination costs	0	(-)	(-)(-)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	0	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline.

6.3. Coherence

6.3.1. Internal coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with other actions, programmes and initiatives under Horizon Europe, in particular European Partnerships (internal coherence).

Strong synergies should be established between the two proposed aviation partnerships, Integrated Air Traffic Management¹¹⁰ and Clean Aviation, and several other proposed initiatives. This should ensure compatibility between the solutions developed by Clean Aviation, and the advanced ATM approaches developed under the Integrated Air Traffic Management initiative. For example, one of the main objectives is the environmental optimisation of air traffic operations in the European airspace. This optimisation requires optimisation in aircraft design and comprehensive meteorological data including different atmospheric parameters. Aligned roadmaps for new aircraft designs and operations, ATM and use of meteorological data will enable the instantaneous calculation of the climate impact caused by the engine emissions released at any point in the four-dimensional space (latitude, longitude, altitude, time).

Cooperation, and the alignment of research agendas, between partnerships is a key condition for success. For instance, the hydrogen initiative and the batteries initiative (potentially delivering alternative energy sources to aviation) could have a huge impact as enablers of zero-emission aviation, if their deliverables respond to the needs of the aviation sector (see Figure in Section 1.4).

Creating synergies would benefit all these initiatives. It is worth mentioning that more-electric aircrafts will require advancements in high-voltage electric power systems, which at high altitudes pose additional safety risks that have to be addressed and technological solutions to be validated. That's why aircraft requirements have to be taken into consideration at initial stages of proposed solutions.

Depending on the selection of the most promising technologies, and the practical research and innovation requirements expressed in the strategic research and innovation agenda, closer cooperation with other initiatives may be envisaged. An overview is available in annex 2.6.

For the **baseline option**: synergies and coherence between Clean Aviation and other initiatives would require an additional level of coordination. Exploiting potential synergies would be hampered by the difference in focus (low TRL versus high TRL) and the more limited scope of lower TRL projects. The baseline option is more appropriate for

¹¹⁰ <https://www.sesarju.eu/approach/environment>

collaborative research/incremental improvements whereas the initiative would focus on disruptive technologies and high TRL demonstrators.

For **Option 1**: The Co-Programmed option would be able to provide this coherence, notably in the context of work programme preparation. The European Commission could ensure coordination at the level of research agendas. Option 1 is not considered optimum to address the complex R&I chains typical for aviation.

For **Option 2**: The institutionalised partnership would allow for greater internal coherence than the two other options, expanding the possibilities of coordination and exploitation of synergies offered by the Co-Programmed option by the existence of the central coordination level, managed by the programme office and supported by the European Commission. This would also enable the development of a shared vision and better exploitation of synergies from joint programmes and calls, in areas such as hydrogen and battery technology,

6.3.2. *External coherence*

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with their external environment, including EU-level programmes and initiatives beyond the Framework Programme and/or national and international programmes and initiatives, but as well as with overarching framework conditions, such as regulation, standardisation, etc. (external coherence).

The **baseline** option and the **co-programmed** partnership are assessed to be less effective than an institutionalised partnership in creating the required systemic effects. This is due to their weaknesses in addressing the international community, ensuring adequate coordination with other programmes, third countries and international organisations, aligning with their own R&D agendas and low carbon roadmaps, and for facilitating market uptake support to be put in place.

The **institutionalised partnership** option, through its programme office, has a dedicated structure that provides a large value in organising systematic links with stakeholders, for establishing a structured dialogue with MS (SRG) or to exploit synergies with ERDF. This is the more important because synergies and sequencing with other EU, national, and regional R&I programmes will help in creating a critical mass to support breakthrough technologies in clean aviation.

In case other initiatives with large potential for synergies (e.g. hydrogen) would become an Article 187 partnership, then there could be a fluent cooperation between the various programme offices.

In addition, it will promote economies of scales, non-duplication and best practices with and among national and regional programs; promote participation of less active countries; and bridge the gap between R&I and national policies on new skills and jobs.

This applies also for setting ambitious standards and performance targets. Working with Member States and international standardisation bodies, the European Commission identifies areas where standards and performance targets could have the greatest impact towards aviation climate neutrality and could propose the development of other standards if needed.

Research provides results, and in this case enables climate neutrality, only when it leads to innovations that enter the market. Trends in EU policies such as the review of the energy

taxation framework, aircraft certification processes, carbon taxation schemes, the Air Quality Directives, as well as the Emissions Directives may create barriers to innovation or on the contrary stimulate research and innovation towards climate neutral aviation by 2050.

For maximising results, research and innovation must be part of a much broader EU strategy encompassing EU programmes, national and international policies.

To ensure continued progress, barriers to innovation as well as accelerators need to be addressed holistically in all EU policies in close cooperation with stakeholders¹¹¹.

All the synergies should be aligned in a shared, integrated and comprehensive roadmap. Combining resources and funding will produce a substantial leverage effect and help reach the objective of climate neutral aviation.

Figure 6 Overview of the options' potential for ensuring and maximizing coherence

	Option 0: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Internal coherence	0	0/+	++
External coherence	0	+	++

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.4. Tabular comparison of options and identification of preferred option

Figure 7 Overall scorecard of the policy options for all criteria

	Items	Baseline Traditional calls	Option 1: Co-programmed	Option 2: Article 187
Effectiveness	Scientific impact			
	Acceleration of the development of know-how and the process of maturing technologies and knowledge transfer for key new technologies and 'differentiators	0	+	++
	Increased diffusion of scientific excellence and high-quality knowledge in the field of aeronautics among research staff from universities, research institutes or private companies	0	+	+
	Increased collaboration with other sectors and integration of areas of fundamental research that are not traditionally within the aeronautical scientific ecosystem	0	+	++
	Strengthened innovation pipeline by creating better directionality of research;	0	+	++

Coherence	Internal coherence	0	+	++
	External coherence	0	+	++
Efficiency	Overall cost	0	-	--
	Cost-efficiency	0	0	-

Notes: Scores for effectiveness and coherence: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline Scores for efficiency: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline

Overall, the implementation of the Clean Aviation initiative through an institutionalised partnership established under Article 187 of TFEU is the preferred option as it would best ensure that private and public sectors remain fully engaged in the development and implementation of a long-term strategy for clean aviation R&I.

It is also consistent with the aim of leveraging industrial financial and in-kind resources, strive towards synergies with national programmes, and create ties with the broader policy initiatives to support to facilitate market uptake. This way, the impact of funding provided by the Commission is maximised.

This form of partnership would continue to provide a stable framework for encouraging the participation of organisations from all concerned sectors (including those outside the traditional aviation industry), securing and allocating resources, managing a wide range of RD&I projects favouring high TRL and creating synergies with other partnerships and initiatives within and outside the Climate, Energy and Mobility Cluster.

It is also considered appropriate to develop a strategy for Clean Aviation that is fully aligned with European Green Deal priorities, and especially the European climate commitment, and with several sustainable development goals.

As documented in the CS2 mid-term evaluation, elements of the CS2 procedural structure are constraining the R&I effort. One objective in Horizon Europe is to optimise the structure of the partnership, in reply to the mid-term evaluation recommendations. This is seen as a key condition for having an Art. 187 partnership. Without such optimisation, a co-programmed partnership could become the better option.

Conclusion:

Three options have been considered **under the Clean Aviation** initiative: traditional calls, a co-programmed partnership and an Article 187 institutionalised partnership. The other

options, a co-funded partnership and an Article 185 partnership, were discarded at an early stage because Clean Aviation builds upon a strong and long-term commitment of industry.

The traditional calls (baseline option) would support a substantial effort for the **exploration of novel solutions**, but it would miss the long-term planning, and large long-term industry commitment, leading to high TRL technology demonstrators required for achieving the Green Deal. In addition, those novel solutions would take far too long to reach TRL 6 stage to be useful for achieving the European Green Deal’s climate neutrality targets on time.

In order to achieve large-scale integrated demonstrators there is a need for a management structure providing in-house programme management capacities, which would allow for close monitoring and swift adaptation of the research and innovation priorities in the course of the programme implementation.

A **co-programmed partnership** would be an improvement compared to traditional calls but would require a very heavy programme management and would lack flexibility.

The dedicated programme office foreseen under the **Article 187 institutionalised partnership** is vital for programme management of large-scale integrated demonstrators. In fact, one of the perceived weaknesses of Clean Sky 2 is that the programme office should have even better governance and programme/ project management capabilities.

In addition, the Article 187 institutionalised partnership ensures long-term commitment of the industry around the European Green Deal climate neutrality target as well as a precise timeline (up to 55% emission reduction by 2030, climate neutrality by 2050), which is vital for the envisaged research which is directly contributing to the European Green Deal climate neutrality target.

The following comparison between the preferred option and the current partnership existing in the area taking into account lessons from past evaluations.

What continues	What is different
<p>Strategic research and innovation agenda as basis for research and innovation activities.</p> <p>Dedicated structure of programme office managed by executive director</p>	<p>The European Green Deal sets a very clear ambition with corresponding target dates. This gives a much stronger focus compared to CS 2.</p> <p>Focus on disruptive research instead of incremental changes.</p> <p>Commitment of industry beyond research and towards market introduction</p> <p>Selection of a very limited number of most promising technologies, with high potential for market introduction, and a business plan on how to get there.</p> <p>Much simplified programme structure with projects selected by open calls instead of pre-allocation of budgets.</p> <p>Better involvement of Member States and the Scientific Community.</p> <p>Strong focus on analysis, project progress monitoring and</p>

	impact assessment.
--	--------------------

Annex 6.11 gives an overview of the weaknesses of the H2020 CS2 Joint Undertaking and how these could be addressed when establishing a new Article 187 Partnership.

7. THE PREFERRED OPTION

In the below table, the alignment of the preferred option of Institutionalised European Partnership under Article 187 TFEU with the selection criteria for European Partnerships defined in Annex III of the Horizon Europe Regulation is depicted.

Seeing that the design process of the candidate Institutionalised Partnerships is not yet concluded and several of the related topics are still under discussion, the criteria of additionality/directionality and long-term commitment are covered in terms of *expectations* rather than ex-ante demonstration.

Alignment with the selection criteria for European Partnerships

Criterion	Alignment of the preferred option
Higher level of effectiveness	<p>An institutionalised partnership would be more effective in achieving the objectives of the initiative within the timeframe set by the Green Deal.</p> <p>This the more important considering the global impact of the European aviation industry, and the global environmental challenges to be addressed.</p> <p>An institutionalised partnership would be considerably more effective in addressing global challenges and delivering research and innovation objectives, in securing EU competitiveness and,</p> <p>The institutionalised partnership would also be effective in securing sustainability (the final goal of “clean aviation”), in strengthening the European Research and Innovation Area, in securing the competitiveness of our industry, and where relevant, in contributing to international commitments (e.g. on standards).</p>
Coherence and synergies	<p>A dedicated management structure similar to the Programme Office in current CS 2 would operate on basis of but with an optimised governance structure, bringing the CS 2 mid-term evaluation recommendations to practice.</p> <p>Projects would be selected by open calls, on the basis of the Strategic Research and Innovation Agenda.</p> <p>Under the supervision of the European Commission, the institutionalised partnership could ensure where possible synergies with relevant strategies and programmes developed by other partnerships and initiatives, in particular in areas such as Clean Hydrogen, Integrated Air Traffic Management and Battery Technology. It would strive towards active coordination and exploiting synergies with national aviation research programmes.</p> <p>This would enable the gradual development of a shared vision and better exploitation of synergies from joint programmes and calls.</p>
Transparency and openness	<p>An institutional partnership would ensure that the outputs of R&I programmes are transparent and available to stakeholders inside and outside the aeronautics industry. The framework governing participation would allow any organisation meeting defined criteria to participate, with a proportion of funded activity subject to open calls.</p> <p>An institutionalised partnership would be better placed to identify priorities and objectives in terms of expected results and impacts, in involving partners and stakeholders from across the entire aviation value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness.</p> <p>SMEs would have the most appropriate support from the partnership, similar to CS 2.</p>

Criterion	Alignment of the preferred option
	<p>An institutional partnership would ensure that the outputs of RD&I programmes are transparent and available to stakeholders inside and outside the aviation community.</p> <p>The approach of using open calls would allow any organisation meeting defined criteria to participate, in an open and transparent way. This framework could provide support and guidance, help networking and build up consortia when addressing complex projects throughout the whole value chain</p>
Additionality and directionality	<p>Only a partnership would be able to secure the necessary industry commitments. The partnership should start on basis of a strategic research and innovation agenda for aeronautical-related R&I and establish a set of common objectives governing the direction, outputs and timeframe of R&I activity under Horizon Europe. This SRIA should, at best, fit within a larger EU aviation policy and strategy.</p> <p>An institutionalised partnership would be very well placed to maintain an Strategic Research and innovation agenda, and adapt it on basis of research results and progressive insights.</p> <p>The active and long term involvement of private as well as public partners would ensure flexibility of implementation and permit to adjust to changing policy, societal and/or market needs, and increase policy coherence between regional, national and EU level.</p>
Long-term commitment	<p>In the case of institutionalised European Partnerships, established in accordance with article 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments</p>

7.1. Operational Objectives

Clean Aviation low and zero emissions technologies will allow fuel efficiency gains of one-third to one-half in 2050, compared to today's fleet.

To deliver on the identified objectives, an initiative in this area must enable aircraft, engines and systems to utilise the full potential of low or zero carbon fuels, including potential disruptive innovations such as hydrogen. Together these outcomes will accelerate the transition towards climate-neutrality.

The ambition of the Clean Aviation Partnership is to ensure that breakthrough technology advancements allow **new aircraft developments by 2030**, with maximum progress towards climate neutral aviation, while meeting socio-economic expectations and providing benefits for European society and businesses. It will go well beyond previous framework programme R&I, and will accelerate the transition towards a climate neutral system by enabling all-new aircraft platforms and configurations, and taking a system-wide approach. To deliver on its objectives, the initiative must aim to bring about decisive steps in new aircraft performance demonstrated and **on offer to airlines and operators by 2030 and available by 2035**. The focus will be on pursuing two pivotal aircraft demonstration efforts for the validation of selected technologies. **Ultra-efficient short-medium range aircraft** coupled with the use of sustainable aviation fuels, and **hybrid electric regional and short-range aircraft** will deliver major steps, together with optimised green trajectories and operations and with accelerated transition to low or zero carbon fuels. Clean Aviation will develop in parallel the technologies to deliver full climate-neutrality by 2050, by bringing key technologies to a maturity that can allow appropriate scaling across the full spectrum of aircraft segments and flight operations, including long-haul travel.

The technical details are worked out in an (approved) Strategic Research and Innovation Agenda¹¹² (SRIA) prepared by the private sector in response to the Clean Aviation initiative.

¹¹² http://clean-aviation.eu/files/Clean_Aviation_SRIA_16072020.pdf

The primary focus of the demonstration efforts will be on the hybrid electric regional and the ultra-efficient short-medium range aircraft concepts, with a stepwise development and demonstration strategy.

This allows for opportunities for technology spin-off to other aircraft categories (commuter and vertical lift applications, long range applications) and for a broad-based participation in the programme, and a much broader and deeper penetration of the overall air transport system with important additional environmental and climate-related benefits.

Note: The SRIA contains a table (page 20) indicating the targets set by the aviation sector for achieving impact linked to the Green Deal with 2030 and 2050 deadlines, confirming the ambition to reach climate neutrality by 2050.

An **Impact Monitor** mechanism and work programme will be included in the Partnership’s work breakdown structure to ensure regular strategic monitoring and steering, and ensure objectives are met. The performance levels in targeted the aircraft types to be demonstrated in Clean Aviation are below.

7.2. Monitoring indicators

We have identified a number of short, medium and long-term monitoring indicators to enable the progress of the partnership towards meeting its objectives to be tracked. However, it is indicated that the development of technologies within EU-funded R&I is limited to TRL 6 activities and additional product development and integration is necessary before first flight and entry into service. Furthermore, the societal impact of the aviation R&I is apparent and quantifiable at least ten years after TRL 6. Having these in mind, the monitoring indicators are shown in the below table.

Monitoring indicators in addition to the Horizon Europe key impact pathway indicators

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
Scientific impact	Alignment of European fundamental and collaborative aeronautics research with medium/long term industry objectives. Cross-fertilisation with other S&T initiatives from relevant areas in Pillar I and II of HE.	Number of times that journal citations generated by the partnership are cited in the global literature Number of occupied and advertised jobs in aeronautical-related R&I Number of PhD thesis, inventions and patents.	Number of patents registered by the aeronautical industry and research organisations located in Europe
Technological / economic impact	Number of programmed projects involving organisations outside the aeronautical industry Number of programmed projects with a documented strategy identifying the potential application of results	Number of programmed projects leading to validated demonstration of new applications of technology Number of years for programmed projects to reach TRL 6 Level and intensity of the	Performance of engine ground demonstrators and/or flying test beds for emissions and noise. Reliability and cost reduction achieved from manufacturing technologies and the projected integration.

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
	to defined market needs	aeronautical-related R&I (in percentage of turn-over) Number of joint ventures or suppliers ready to invest further in the development and integration beyond TRL 5-6	Number of programmed projects with high potential for market take-up Projected value of exports generated by the European aeronautical sector (note this will be significantly beyond year 5+) Projected direct and indirect employment generated by the European aeronautical sector
Societal impact	Number of programmed projects developing technological solutions towards climate neutrality	Level and intensity of the aeronautical-related R&I (in percentage of turn-over) Education and training of students and staff in new technological field	Maintain and/or increase European competitiveness and employment. Level of matching funds from National or International funding mechanisms required to integrate, integrate and certify developed technologies. Changes in air quality and well-being (note this will be significantly beyond year 10+)
Incl. Environmental / sustainability impact	Number of programmed projects focusing on large civil aircraft Number of programmed projects focusing on sustainable aviation fuels integration	Number of programmed projects focusing on alternative energies or technologies. Potential and scalability successfully demonstrated and quantified	Changes in CO ₂ , non- CO ₂ emissions and noise generated by the aviation industry in Europe and globally (note this will be significantly beyond year 10+)

Source: Steer analysis

7.3. Evaluation framework

The evaluation of the Partnership will be done in full accordance with the provisions laid out in Horizon Europe Regulation Article 47 and Annex III, with external interim and ex-post evaluations feeding into the overall Horizon Europe evaluations. As set in the criteria for European Partnerships, the evaluations will include an assessment of the most effective policy intervention mode for any future action; and the positioning of any possible renewal of the partnership in the overall European Partnerships landscape and its policy priorities. In the absence of renewal, appropriate measures will be developed to ensure phasing-out of framework programme funding according to conditions and timeline agreed, ex-ante, with the legally committed partners.

Annex 1 Procedural information

1. LEAD DG, DECIDE PLANNING REFERENCES

Lead DG: Directorate-General Research and Innovation (RTD)

Decide number: PLAN/2019/5304

2. ORGANISATION AND TIMING

Institutionalised partnerships are foreseen in Articles 185 and 187 of the Treaty on the Functioning of the European Union (TFEU). The preliminary agreement on Horizon Europe contained a list of possible areas for institutionalised partnerships based on Articles 185 and 187. For these areas, the Commission considered 12 potential institutionalised partnerships. Their set up involves new EU legislation and the establishment of dedicated implementing structures and therefore an impact assessment for each of these initiatives.

Following political validation in June 2019, the impact assessment process started with the publication of inception impact assessments for each initiative in August 2019.

An inter-service steering group (ISSG) on research and innovation partnerships under Horizon Europe was set up in May 2019 and held four meetings before submission of the Staff Working Document to the Regulatory Scrutiny Board (7 May 2019, 19 June 2019, 5 December 2019, and 20 January 2020). The ISSG consisted of representatives of: the Secretariat-General; Directorate-General for Budget; Directorate-General for Research and Innovation; Directorate-General for Communications Networks, Content and Technology; Directorate-General for Mobility and Transport, Directorate-General for Internal Market, Industry, Entrepreneurship and SMEs, Directorate-General for Energy; Directorate-General for Environment; Directorate-General for Climate Action; and the Legal Service.

An online public stakeholder consultation was launched between September and November 2019, receiving 1635 replies for all 12 initiatives.

3. CONSULTATION OF THE RSB

Two upstream meetings with the Regulatory Scrutiny Board were held on 10 July 2019 and 30 September 2019.

In accordance with the feedback received from the Regulatory Scrutiny Board on 12 June 2020 the Staff Working Document has been revised as presented in Figure 1. The impact assessment was endorsed by the Inter Service Steering Group on 20 January 2020.

4. EVIDENCE, SOURCES AND QUALITY

To ensure a high level of coherence and comparability of analysis for all candidate initiatives, an external study was procured to feed into the impact assessments of the 12 candidate institutionalised partnerships¹. It consisted of a horizontal analysis and individual thematic analyses for each of the initiatives under review.

For all initiatives, the evidence used includes desk research partly covering the main impacts and lessons learned from previous partnerships. A range of quantitative and qualitative data

¹ Technopolis Group, 2020, forthcoming.

sources complement the evidence base, including evaluations; foresight studies; statistical analyses of framework programmes application and participation data and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options. Public consultations (open and targeted) supported the comparative assessment of the policy options. For each initiative up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition the analysis was informed by the results of the Public Consultation (Sept. – Nov. 2019), the consultation of the Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of candidate Institutionalised European Partnerships.

A more detailed description of the methodology and evidence base used, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

Figure 1 Modifications to the draft Staff Working Document based on comments received from the Regulatory Scrutiny Board

Comments from the Regulatory Scrutiny Board	Actions taken for the Staff Working Document
<p>The report should be clearer about the differences between the new partnership and the current one and the underlying drivers (e.g. evaluation results, policy or market developments).</p>	<p>The report, mainly chapter 1, has been updated to better reflect the underlying drivers of the proposed initiative.</p> <p>A summary table, on page 67, compares the preferred option to the current partnership. In addition, an annex 6.11 has been added including a table indicating the changes to the Clean Aviation initiative to address the perceived shortcomings of Clean Sky 2 (source Clean Sky 2 mid-term evaluation and impact assessment study)</p>
<p>The report should clarify how the proposed two-pronged approach would work in practice. It should explain the links between the foreseen actions under the traditional calls for collaborative research and the institutionalised partnership. It should explain to what extent these approaches address different problems and have distinct objectives.</p>	<p>The problems addressed by the Clean Aviation initiative have been better explained in chapter 2 of the report.</p> <p>Point 4.4.3 on priority setting and the level of directionality, has been revised to clarify the distinction between the activities of the Clean Aviation initiative and collaborative research, and how these relate to each other.</p>
<p>The report could explain better the links with other EU policies and instruments in place to support aviation and to tackle its climate and environmental impacts</p>	<p>The revised report explains how activities are linked.</p> <p>Specifically, the revised report, mainly Chapters 1.3 and 4.4.4, address synergies</p>

	<p>while Annex 6.10 contains an initial list of potential synergies.</p> <p>Chapter 3.2 emphasizes the role of the Commission to ensure co-operation between various policy areas, and national programmes.</p> <p>Note also that one of the specific objectives of the initiative is to expand and foster the integration of the aviation R&I value chains, including SMEs, also by exploiting synergies with other initiatives national and European related programmes.</p>
<p>The report should specify more precisely the environmental and climate impacts the initiative will address. It should discuss the extent to which the partnership would be able to deliver these ambitious objectives. In this regard, the report should better explain the foreseen sequencing and expected timing of the forthcoming disruptive technologies.</p>	<p>The environmental impact of aviation is better explained in Annex 6.3. A paragraph has been added to Point 4.1, explaining why the focus on climate neutrality by this initiative is justified.</p> <p>The Clean Aviation initiative will primarily focus on the Green Deal’s ambition to reduce net greenhouse gas emissions. This has been made clearer in the description of the objectives and specific objectives.</p>
<p>The report should explain how the new partnership would be better able to attract relevant stakeholders and Member States. It should discuss whether smaller companies with potential to provide disruptive solutions are likely to be interested in traditional calls, instead of applying for the partnership.</p>	<p>The two-pronged approach (a focussed Clean Aviation, and a complementary collaborative research programme) is explained on page 32 of the main report. This is further detailed in Chapter 4.4.3.</p> <p>An Annex 6.9 has been added confirming the commitment and involvement of the private sector and stakeholders to the Clean Aviation initiative.</p> <p>In addition, the private sector has finalised a Strategic Research and Innovation Agenda (SRIA).</p> <p>The most recent public consultation (statistics also included in Annex 6.9), which was part of the SRIA’s preparation process, received a remarkable high number of positive reactions from SMEs (16%) and private citizens (36%).</p> <p>Overall, the feedback was very positive on the ambition and focus of the presented SRIA, and the stakeholders’ interest in participating.</p>

<p>The report should clarify the logic behind the intervention. It could better explain the links between problems and objectives, and between objectives, targeted impacts and functionalities. The intervention logic should focus on the part of the “two-pronged” approach that the Clean Aviation partnership would address.</p>	<p>The report has undergone various changes to improve the logic from problems to targeted impacts and functionalities; this effort was based on the replies given to the questions asked by the Regulatory Scrutiny Board before and during the hearing with the RSB.</p> <p>The revised intervention logic is focussing on the Clean Aviation partnership activities. The collaborative research is not addressed as this is outside the scope of the partnership.</p>
<p>The report should integrate the latest realistic expectations on the effects of the Covid-19 crisis on the aviation sector. It should consider these in the analysis of the problems, baseline and impacts.</p>	<p>The COVID-19 crisis is still on-going and insights in the potential impact still evolving.</p> <p>The text related to COVID-19 under Chapter 1 has been changed, adding the position of stakeholders that are involved in the preparations for the proposed initiative to protect the focus of the Clean Aviation initiative on its Green Deal-oriented objectives.</p> <p>An Annex 6.2 has been added with a summary of the known information at the moment of writing.</p>

Annex 2 Stakeholder Consultation

1. OVERVIEW FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1.1. Introduction

In line with the Better Regulation Guidelines,² stakeholders were widely consulted as part of the impact assessment process of the 12 candidates for institutionalised partnerships, including national authorities, the EU research community, industry, EU institutions and bodies, and others. These inputs were collected through different channels:

- A feedback phase on the inception impact assessments of the candidate initiatives in August 2019, gathering 350 replies for all 12 initiatives on the “Have your Say” web portal during a three-week period;
- A structured consultation of Member States performed by the EC services 2019 through the Shadow Strategic Configuration of the Programme Committee of Horizon Europe (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.
- An online public stakeholder consultation administered by the EC, based on a structured questionnaire, open between September and November 2019, gathering 1635 replies for all 12 initiatives;
- A targeted consultation run by the external study contractors with a total of 608 interviews performed as part of the thematic studies by the different study teams between August 2019 and January 2020.

1.2. Horizontal results of the Open Public Consultation

The consultation was open to everyone via the EU Survey online system.³ The survey contained two main parts to collect views on general issues related to European partnerships (in Part 1) and specific responses related to one or more of the 12 candidate initiatives (as selected by a participant). The survey was open from 11 September until 12 November 2019. The consultation was available in English, German and French, and was advertised widely through the European Commission’s online channels as well as via various stakeholder organisations.

1.2.1. Profile of respondents

In total, 1635 respondents filled in the questionnaire of the open public consultation. Among them, 272 respondents (16.64%) were identified to have responded to the consultation as part of a campaign (coordinated responses). Based on the Better Regulation Guidelines, the groups of respondents where at least 10 respondents provided coordinated answers were labelled as ‘campaigns’, segregated and analysed separately and from other responses. In total 11 campaigns were identified, the largest of them included 57 respondents⁴. In addition, 162

² https://ec.europa.eu/info/files/better-regulation-guidelines-stakeholder-consultation_en

³ <https://ec.europa.eu/eusurvey/runner/ConsultationPartnershipsHorizonEurope>

⁴⁴ The candidate Institutionalised Partnership Clean Hydrogen has the highest number of campaigns, namely 5. A few initiatives, such as Innovative SMEs, Smart Networks and Systems, were not targeted by campaigns. Some campaign respondents decided to provide opinions about several partnerships.

respondents in the consultation also display similarities in responses but in groups smaller than 10 respondents. Hence, these respondents were not labelled as campaigns and therefore were not excluded from the general analysis.

Table 1: Country of origin of respondents (N=1635)

Country	Number of respondents	Percentage of respondents
Germany	254	15.54%
Italy	221	13.52%
France	175	10.70%
Spain	173	10.58%
Belgium	140	8.56%
The Netherlands	86	5.26%
Austria; United Kingdom	61	3.73%
Finland	49	3.00%
Sweden	48	2.94%
Poland	45	2.75%
Portugal	32	1.96%
Switzerland	28	1.71%
Czechia	24	1.47%
Greece	23	1.41%
Norway; Romania	22	1.35%
Denmark	20	1.22%
Turkey	19	1.16%
Hungary	14	0.86%
Ireland	12	0.73%
United States	11	0.67%
Estonia; Slovakia; Slovenia	10	0.61%
Bulgaria; Latvia	9	0.55%
Bosnia and Herzegovina	7	0.43%
Lithuania	4	0.24%
Canada; Croatia; Israel	3	0.18%
China; Ghana; Iceland; Japan; Luxembourg; Morocco	2	0.12%
Bhutan; Botswana; Cyprus; Iran; Malta; Mexico; Moldova; Mongolia; Palestine; Russia; Serbia; South Africa; Tunisia; Ukraine; Uruguay	1	0.06%

As shown in Figure 2, the three biggest **categories of respondents** are representatives of companies and business organisations (522 respondents or 31.9%), academic and research institutions (486 respondents or 29.7%) and EU citizens (283 respondents or 17.3%). Among the group of respondents that are part of campaigns, most respondents are provided by the same groups of stakeholders, namely company and business organisations (121 respondents or 44.5%), academic and research institutions (54 respondents or 19.8%) and EU citizens (42 respondents or 15.4%).

Figure 2 Type of respondents (N=1635) - For all candidate initiatives

Among all consultation respondents, 1,303 (79.69%) have been **involved in the on-going research and innovation framework programme** Horizon 2020 or the preceding Seventh Framework Programme, while 332 respondents (20.31%) were not. In the group of campaign respondents, the share of those who were involved in these programmes is higher (245 respondents out of 272 or 90.07%) than in the group of non-campaign respondents (1058 out of 1,363 or 77.62%). When respondents that participated in the Horizon 2020 or in the preceding Seventh Framework Programme were asked to indicate in which capacity they were involved in these programmes, the majority stated they were a beneficiary (1,033 respondents) or applicant (852 respondents). The main stakeholder categories, e.g. companies/business organisation, academic/research institutions, etc., show a similar distribution across the capacities in which they ‘have been involved in Horizon 2020 or in the Seventh Framework Programme’ as the overall population of consultation respondents.

Among those who have been involved in Horizon 2020 or the preceding Seventh Framework Programme, 1,035 respondents (79.43%) are/were **involved in a partnership**. The share of respondents from campaigns that are/were involved in a partnership is higher than for non-campaign respondents, 89.80% versus 77.03% respectively.

1.2.2. Characteristics of future candidate European Partnerships

Respondents were asked to assess what areas, objectives, aspects need to be in the **focus of the future European Partnerships** under Horizon Europe and to what extent. According to Figure 6, a great number of respondents consider that a significant contribution by the future European Partnerships is ‘fully needed’ to achieve climate-related goals, to the development and effective deployment of technology and to EU global competitiveness in specific sectors/domains. Overall, respondents’ views reflect that many aspects require attention of the Partnerships.

Overall, only minor differences can be found between the main stakeholder categories. Academic/research institutions value the responsiveness towards EU policy objectives and focus on development and effective deployment of technology a little less than other respondents. Business associations, however, found that the future European Partnerships under Horizon Europe should focus a little bit more on the development and effective deployment of technology than other respondents.

Figure 6: To what extent do you think that the future European Partnerships under Horizon Europe need to (N=1363) (non-campaign replies) For all candidate initiatives

1.2.3. Main advantages and disadvantages of Institutionalised European Partnerships

An open question asked respondents to outline the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe (1,551 respondents). The advantages mentioned focus on the development of technology, overall collaboration between industry and research institutions, and the long-term commitment. Disadvantages mentioned are mainly administrative burdens. An overview is provided below.

Advantages mentioned: Long term commitment, stability, and visibility in financial, legal, and strategic terms; Participation of wide range of relevant stakeholders in an ecosystem (large/small business, academics, researchers, experts, etc.); Complementarity with other (policy) initiatives at all levels EU, national, regional; Efficient and effective coordination and management; High leverage of (public) funds; Some innovative field require high levels of international coordination/standardisation (at EU/global level); Ability to scale up technology (in terms of TRL) through collaboration; Networking between members; Direct communication with EU and national authorities

Disadvantages mentioned: Slow processes; System complexity; Continuous openness to new players should be better supported as new participants often bring in new ideas/technologies that are important for innovation; Lower funding percentage compared to regular Horizon Europe projects; Cash contributions; Administrative burdens; Potential for IPR constraints.

1.2.4. Relevance of EU level to address problems in Partnerships' areas

Respondents were asked to rate the **relevance of research and innovation efforts at EU level efforts to address specific problems in the area of partnerships**. Research and innovation related problems were rated as most relevant across all candidate initiatives, followed by structural and resources problems and problems in the uptake of innovations.

Overall, all three areas were deemed (very) relevant across the partnerships, as more than 80% of respondents found these challenges (very) relevant across the partnerships. Only minor differences were found between stakeholder categories. Research and innovation problems were found slightly more relevant by academic/research institutions, yet slightly less relevant by large companies and SMEs. Structural and resource problems were indicated as slightly more relevant by NGOs, but slightly less by academic/research institutions. While both NGOs and public authorities found it slightly more relevant to address problems in uptake of innovation than other respondents. The views of citizens are not significantly different. Respondents that are/were directly involved in a current/preceding partnership find, however, the need to address problems related to the uptake of innovations was slightly more relevant than other respondents.

Figure 9: To what extent do you think this is relevant for research and innovation efforts at EU level to address the following problems in relation to the candidate partnership in question? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.5. Horizon Europe mode of intervention to address problems

Respondents were asked to indicate how these challenges could be addressed through **Horizon Europe intervention**. Just over 50% of all respondents indicated that institutionalised partnerships were the best fitting intervention, with relatively strong differences between stakeholder categories. The use of Institutionalised Partnership was favoured more by business associations and large companies, but less by academic/research institutions and SMEs. While academic/research institutions valued traditional calls more often, this was not the case for business associations, large companies and public authorities. Public authorities indicated a co-programmed intervention more often than other respondents. Citizens indicated slightly less often that institutionalised partnerships were the best fitting intervention. Respondents that are/were directly involved in a current/preceding partnership, selected the institutionalised partnership intervention in far higher numbers (nearly 70%).

Figure 10: In your view, how should the specific challenges described above be addressed through Horizon Europe intervention? (non-campaign replies) For all candidate initiatives

When asked to reflect on their answers, respondents that pointed to the need for using institutionalised partnerships mentioned the long-term commitment of collaboration, a common and ambitious R&I strategy as well as the overall collaboration between industry and research institutions. Others shared positive experiences with other modes of interventions:

- Traditional calls, because of their flexibility and integration of a wide range of actors, as long as the evaluation panels do not deviate from the policy focus. This was mentioned by 94 participants, including companies (25), academics (26) and EU citizens (25).
- Co-funded partnership, as a mechanism to ensure that all participants take the effort seriously, while allowing business partnerships to develop. This approach was deemed suitable based on previous experiences with ERANETs. This was raised by 84 participants, 36 of them academic respondents, 18 companies and 16 EU citizens.
- Co-programmed partnerships, to tackle the need to promote and engage more intensively with the private sector. This was mentioned by 97 participants, most of them companies (34), followed by academics (22), business associations (15) and EU citizens (11).

1.2.6. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Setting joint long-term agendas

Respondents were asked how relevant it is for the proposed European Partnerships to meet their objectives to have a strong involvement of specific stakeholder groups in setting joint long-term agenda. All respondents see stakeholders from industry as the most relevant, followed by academia and governments. The involvement of foundations and NGOs as well as other societal stakeholders were, however, still found to be (very) relevant by more than 50% of the respondents. Most respondents indicated the stakeholder group they belong to themselves or that represent them as relevant to involve.

Figure 11: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Setting joint long-term agenda with strong involvement of: (non-campaign replies) For all candidate initiatives

Pooling and leveraging resources through coordination, alignment and integration with stakeholders

Respondents were asked how relevant it is for the proposed European Partnership to meet its objectives to pool and leverage resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with specific groups of stakeholders. Respondents see stakeholders from industry as the most relevant, followed by academia and governments (Member States and Associated Countries). The involvement of foundations and NGOs as well as other societal stakeholders are also still found to be (very) relevant for more

than 50% of the respondents. Similarly as described for the question on setting joint long-term agendas, most stakeholder categories valued their own involvement higher than other respondents – although also here differences between stakeholder categories were minor.

Figure 12: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Pooling and leveraging resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with: (non-campaign replies) For all candidate initiatives

Composition of the partnerships

Regarding the composition of the partnership most respondents indicated that for the proposed European Partnership to meet its objectives the composition of partners needs to be flexible over time and that a broad range of partners, including across disciplines and sectors, should be involved (see Figure 13). When comparing stakeholder groups only minor differences were found. Academic/research institutions and public authorities found the involvement of a broad range of partners and flexibility in the composition of partners over time slightly more relevant than other respondents, while large companies found both less relevant. SMEs mainly found the flexibility in the composition of partners over time less relevant than other respondents, while no significant differences were found regarding the involvement of a broad range of partners. Citizens provided a similar response to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, indicated a slightly lower relevance of involving a broad range of partners and flexibility in the composition of partners over time.

Figure 13: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Partnership composition (non-campaign replies) Aggregation of responses of all candidate initiatives

Implementation of activities

Most respondents indicated that implementing activities like a joint R&I programme, collaborative R&I projects, deployment and piloting activities, providing input to regulatory aspects and the co-creation of solutions with end-users are all (very) relevant for the partnerships to be able to meet its objectives. Minor differences were found between the main stakeholder categories, the differences found were in line with their profile. As such, academic/research institutions found joint R&I programme & collaborative R&I projects slightly more relevant and deployment and piloting activities, input to regulatory aspects and co-creation with end-users slightly less relevant than other respondents.

For SMEs an opposite pattern is shown. Large companies, however, also found collaborative R&I projects slightly more relevant than other respondents, as well as input to regulatory aspects. The views of citizens are similar to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, show a slightly higher relevance across all activities.

Figure 14: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Implementing the following activities (non-campaign replies) For all candidate initiatives

1.2.7. Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Respondents were asked to reflect on the relevance of setting up a legal structure (funding body) for achieving a set of improvements, as shown in the below Figure. In general, 70%-80% of respondents found a legal structure (very) relevant for these activities. It was found

most relevant for implementing activities in a more effective way and least relevant for ensuring a better link to practitioners on the ground, however differences are small.

Figure 15: In your view, how relevant is to set up a specific legal structure (funding body) for the candidate European Partnership to achieve the following? (non-campaign replies) Aggregation of responses of all candidate initiatives

When comparing stakeholder categories there are only minor differences. Academic/research institutions indicated a slightly lower relevance for transparency, better links to regulators as well as obtaining the buy-in and long-term commitment of other partners. SMEs also indicated a lower relevance regarding obtaining the buy-in and long-term commitment of other partners. Large companies showed a slightly higher relevance for implementing activities effectively, ensure better links to regulators, obtaining the buy-in and long-term commitment of other partners, synergies with other EU/MS programmes and collaboration with other EU partnerships.

NGOs found it slightly more relevant to implement activities faster for sudden market or policy needs. Public authorities, however, find it slightly less relevant to facilitate collaboration with other European Partnerships than other respondents. The views of citizens show a slightly lower relevance for a legal structure in relation to implementing activities in an effective way. Respondents that are/were directly involved in a current/preceding partnership indicated a higher relevance across all elements presented.

1.2.8. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Consulted on the scope and coverage for the partnerships, based on their inception impact assessments, the large majority considered that the scope and coverage initially proposed in the inception impact assessments is appropriate. However, about 11-15% of the respondents indicated the scope and coverage to be too narrow. About 11-17% of respondents answered “Don’t know”. Overall, differences between the main stakeholder categories were found to be

minor. Academic/research institutions indicated slightly more often that the research area was “too narrow” than other respondents. SMEs on the other hand indicated slightly more often that the research area and the geographical coverage were “too broad”. NGOs and public authorities, however, found the geographical coverage slightly more often “too narrow”.

Large companies found the range of activities slightly more often “too broad” and the sectoral focus slightly more often “too narrow” when compared to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership more often indicated that the candidate institutionalised European Partnership have the “right scope & coverage”.

Figure 16: What is your view on the scope and coverage proposed for this candidate institutionalised European Partnership, based on its inception impact assessment? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.9. Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

When asked whether it would be possible to rationalise a specific candidate European Institutionalised Partnership and its activities, and/or to better link with other comparable initiatives, nearly two thirds of respondents answered “Yes” (1,000, or 62%), while over one third answered “No” (609, or 39%). Nearly no differences were found between stakeholder categories, only large companies and SMEs indicated slightly more often “Yes” in comparison to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership, indicated “No” more often, the balance is about 50/50 between “Yes” and “No” for this group.

Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Finally, respondents were asked to rate the relevance of partnership specific impacts in three main areas: Societal; Economic/technological; and Scientific impacts. All three areas were deemed (very) relevant across the candidate partnerships. Scientific impact was indicated as the most relevant impact, more than 90% of respondents indicated that this as (very) relevant. Only minor difference between stakeholder groups were found.

Academic/research institutions found scientific impacts slightly more relevant, while large companies found economic and technological impacts slightly more relevant than other respondents. NGOs found societal impact slightly more relevant, while SMEs found this

slightly less important. Citizens did not a significantly different view when compared to other respondents. Respondents that are/were directly involved in a current/preceding partnership find all impacts slightly more relevant than other respondents.

Figure 17: In your view, how relevant is it for the candidate European Institutionalised Partnership to deliver on the following impacts? (non-campaign replies) Aggregation of responses of all candidate initiatives

Stakeholder consultation results for this specific initiative

1.2.10. Feedback to the inception impact assessment on candidate initiatives for Institutionalised Partnerships

Following the publication of the inception impact assessment, a feedback phase of three weeks allowed any citizen to provide feedback on the proposed initiatives on the “Have your say” web portal. In total, 350 feedback responses were collected for all initiatives.

For the initiative “Clean Aviation”, 34 individual feedback responses were collected, mainly from businesses and business associations, academic/research institutions, non-governmental organisations and public authorities.⁵ These responses included the following topics:

- Overall support in achieving climate neutrality in aviation;
- Requirement for further collaboration between stakeholders to accomplish the innovation and impact required for achieving the objectives;
- Persistence of problems in absence of policy intervention;
- Support of EU action to address different aspects of the problem;
- The need to explore, mature and demonstrate new technologies, whilst maintaining competition;
- The potential of Horizon Europe to have significant scientific impacts, delivering economic, technological and societal benefits, while ensuring competitiveness in Europe;
- Support of the implementation of an institutionalised partnership to successfully deliver economic and technological impacts; and
- The need to cooperate with other initiatives to enable cutting-edge technologies to be incorporated into the aviation sector.

1.2.11. Structured consultation of the Member States on European partnerships

The structured consultation of Member States resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.

The thematic coverage for the Cluster Climate, Energy and Mobility is perceived as rather satisfying, with 62% being somewhat satisfied and 10% very satisfied, while 7% each are not very satisfied or not satisfied at all.

Many delegations comment on the **balance of topics and suggest a stronger focus on the environment and climate**, as well as energy topics. Mobility is considered too prominent and should be rationalised further. The area of transport in particular appears to have a disproportionate number of partnerships, which may result in an under-investment for open calls in this area.

For the initiative “Clean Aviation”, the following overall feedback was received from Member States.

Relevance and positioning in a national context

⁵ Feedback on inception impact assessment to be found on https://ec.europa.eu/info/law/better-regulation/initiatives/ares-2019-4972457/feedback_en?p_id=5722372

Overall, the results of the consultation confirm the relevance of the proposed European Partnership on Clean Aviation, with 78% considering it ‘very relevant’ or ‘somewhat relevant’ for their national policies and priorities.

Relevance of the European Partnership on Clean Aviation in the national context

On the question of existing national/regional R&I strategies, plans and programmes in support of the proposed partnership on Clean Aviation, 68% (19 out of 28) countries report that they relevant elements in place.

Feedback on aspects that could be reinforced in the proposal for this partnership in order to increase its relevance for national priorities⁶ underline support for the ambition of reducing the environmental footprint of aviation and achieving a carbon neutral aviation. But, there seems to be a divergence of views on the scope of the partnership and the pathway to achieve this goal. For instance, some delegations underline that **the focus should be on real world introduction of new technologies** (i.e. the next generation of commercial aircraft).

Other comments suggest broadening the scope to focus on short-range transport solutions within urban and developing small/ urban aircraft solutions, and thereby ensure bigger involvement of smaller suppliers for the air industry, and to strengthen the impact narrative beyond environmental (e.g. by including safety needs, international competitiveness goals, quicker in-service introduction).

The majority of countries (57%) are undecided regarding their interest in participating.

Feedback on objectives and impacts

Overall, there was a strong agreement (82%) on the use of a partnership approach in addressing challenges related to EU aviation and the development and demonstration of aircraft technologies. There was broad agreement (71%) that a partnership is more effective in achieving the objectives and delivering clear impacts for the EU and its citizens, and to lesser degree that (56%) it would contribute to improving coherence and synergies within the EU R&I landscape.

⁶ Comments on scope and content have to be assessed in the context of the overall priority setting to ensure coherence.

Member States indicated strong agreement with the proposed objectives for the short, medium and long term (75%) and the expected scientific, economic and societal impacts at European level (75%), with the remaining ones remaining neutral. 71% of countries consider the impacts very or somewhat relevant in the national context. There was overall agreement with the envisaged duration of the proposed partnership with 82% of countries finding it adequate.

In addition, individual comments suggested considering the full life-cycle of the aircraft by including the means of production and disposal, as well as to include under objectives innovative flight design, and redesign of the entire aviation system. In terms of technologies, individual respondents highlighted the importance to cover also aeronautics advance manufacturing technologies and materials, and novel battery technologies.

Views on partners, contributions and implementation

The responses suggested that there is good agreement between countries (57%) on the type and composition of partners. In additional comments, several countries called for opening the proposed partnership to more industries involved in aeronautics, and ensuring broad participation of new and small players. There are some countries expressing support for a model with a core group of partners steering the European Partnership, whilst ensuring appropriate involvement of participants from other sectors.

The majority of countries (71%) found that there was insufficient information to assess the nature of contributions and level of commitment from the partners, notably on the introduction of financial contributions from industry.

The proposed mode of implementation in the form of Article 187 TFEU is supported by 46% of countries, whilst three countries. Additional comments suggest considering a co-programmed model for implementing the priority, to merge the proposed European Partnership on Integrated Air Traffic Management, and to move away from mode-specific implementation in mobility. Moreover, several delegations (notably from smaller countries) highlighted the need to ensure transparency and openness of the partnership, including the use of open competitive calls.

1.2.12. Targeted consultation of stakeholders

Approach to the targeted consultation

The stakeholder interviews underpin:

- The selection and description of the policy options for the intervention;
- The comparative assessment of options; and
- The assessment of the preferred option in terms of its effectiveness and coherence as well as in relation to the key criteria for European Partnerships (openness and transparency, additionality and directionality, Member States' involvement, and systemic approach and flexibility).

Accordingly, the consultation exercise covered a wide range of organisations in identifying stakeholders, the following criteria were applied:

- The need to discuss the role of a future partnership with key European bodies with a central role in the delivery of EU policy objectives, in particular the European Commission and the CS2 JU itself;
- The need to engage with stakeholders located in all Member States with an interest in the future direction of aviation-related R&I;

- The need to obtain views from both founding and associate members of the CS2 JU, including manufacturers and industry who can provide insights into the costs and benefits of a partnership approach to sponsorship and coordination of R&I;
- The importance of understanding key developments in research through dialogue with universities and other research institutions engaged in pre-competitive R&I in the aviation sector;
- The need to engage with organisations who have had little or no involvement in the existing JU but whose role in the delivery of clean aviation and in ensuring that the sector meets European economic, social and environmental targets is important;
- The importance of engaging with pan-European representative organisations who can provide an overview of the perspectives of specific stakeholder groups, including environmental representatives who can bring diverging views from the aeronautics industry;
- The need to obtain data to support an analysis of the costs and benefits of different policy options.

Overview of respondents to the targeted consultation

The table below describes the number of interviews undertaken by stakeholder category, as well as its proportion of the total.

Stakeholder category	Number	Share (%)
Key European bodies	7	14%
Member State transport authorities	3	6%
Industry and representatives	19	38%
Research organisations and universities	14	28%
Airlines and airports representatives	3	6%
Non-aviation technology organisations	2	4%
European environmental organisations	2	4%
TOTAL	50	100%

Representatives from all stakeholder groups were interviewed to ensure that all groups were represented in the impact assessment.

1.2.13. Key results/messages from the targeted consultation

Political and legal context: Emerging challenges in the field

All stakeholders interviewed were supportive of the proposed objective of achieving climate neutrality by 2050. It was felt that that objective, whilst extremely ambitious, was more encompassing of the effects of aviation and also allowed a more long-term solution to be realised in comparison with those presented under CS2. As well as mitigating the impacts of climate change there was also a consensus that striving towards climate neutrality would

support the longevity of the aviation industry in Europe. Many stakeholders noted that the European aviation industry was facing increased competition from Russia and China, and thus investing in new technologies could also reinforce Europe's position in the global market place.

Problem definition: What are the problems?

Many interviewed stakeholders highlighted the effect of long development and innovation cycles and high associated costs as a contributing factor to the growing ecological footprint, and that a transformative change was required to achieve sustainability in the industry, despite the actuals of this being unclear at this stage. There was recognition amongst stakeholders that investments would have to be made in both airframe and propulsion technologies as well as in alternative fuels to achieve the objective at hand. Most stakeholders noted the importance of EU industrial leadership in the field, especially in the face of increasing competition from China and Russia.

What are the problem drivers?

The development of the problem drivers also took the views of stakeholders into account and were fixed as follows:

- Demand for mobility increases faster than the deployment of technological improvements;
- Improving the environmental performance of the aviation industry is complex, lengthy, costly and risky;
- Economic incentives for greener aviation are not strong enough; and
- Ensuring strong competitiveness of the EU aeronautics industry is complex.

There was widespread recognition amongst stakeholders that current levels of traffic growth were not sustainable in the longer term, especially given this growth currently causes a net increase in emissions.

Stakeholders agreed in part that this was due to long and costly development cycles in the industry, especially when compared with non-aviation industries. At the same time there was also recognition that shifting the aviation industry to cleaner fuels is a more complicated and involved process than implementing changes to land-based transport modes. Some parties mentioned the effective duopoly in the commercial aircraft market as a reason for stifled development.

European environmental organisations and some other stakeholder also highlighted that the current state of the market permits this rapid growth and that this could be reduced through the implementation of taxes on fossil fuels. The implementation of taxes and/or market-based measures could have the effect of both reducing air transport demand and increasing the attractiveness of greener technologies as they become more cost effective.

Stakeholders also noted that presence of regulatory barriers in the context of standard and disruptive technology development, although these considerations were felt less strongly than those. It was noted by some stakeholders that the lack of global integrated standards undermines the benefits of R&I activities developed at an EU level, thus affecting European competitiveness.

How will the problem(s) evolve?

There was a strong consensus, in the absence of policy intervention, that it would not be possible to achieve the long-term strategy and level of stakeholder participation required to achieve the goal of climate neutrality by 2050. The vast majority of stakeholders recognised that the aviation industry has to be more environmentally friendly, if it wants to continue growing in Europe.

At the same time many stakeholders noted that the current regulation in place for CS2 was not always as efficient as required with the majority of stakeholder citing that it was too inflexible and should be reviewed for Horizon Europe. This would enable resources to be allocated more effectively throughout the programme dependent on levels of achievement rather than through pre-determined allocations.

Why should the EU act?

There was widespread recognition of the problem of fragmentation and lack of effective coordination of R&I activity underpinning the case for intervention at the European level. Many stakeholders described a lack of coordination in R&I activities at Member State level and national interests considerations rather than a united European approach. Stakeholders participating in the interview programme and providing feedback on the inception impact assessment were also generally fully supportive of EU action to address these and other aspects of the problem.

Objectives: What is to be achieved?

The vast majority agreed that more focus should be placed on bringing about a transformative change towards sustainability through the development and effective deployment of technology, whilst also making significant contributions towards EU global competitiveness.

There was general support to focus higher proportions of the budget on larger commercial aircraft as resulting developments would have larger impacts compared other airborne modes. The overwhelming majority of stakeholders interviewed supported inclusion of EASA in Clean Aviation, albeit in different roles, to assist in addressing product certification at an earlier stage. Ultimately this should assist in allowing new products to enter the market more quickly.

Likely scientific impacts

Virtually all stakeholders agreed that the objectives would be achieved through the development of airframe, propulsion and fuel technology, all of which would further the advancement of science in materials, aerodynamics, combustion and fuels. During the interview process many research organisations and universities mentioned however that more research results from the partnership should be published.

Likely economic/technological impacts

Most stakeholders regarded the resulting economic and technological impacts from the partnership as being very relevant and were supportive of ensuring increased European industrial leadership as well as the creation of more high-skilled jobs in a low-carbon economy.

Several stakeholders highlighted the importance of encouraging participation from a wide group of stakeholders, including those outside the traditional aviation-market, to assist with the development of innovative technologies. There was a general consensus that EASA

should also have oversight of all developments to ensure that the regulation process does not delay the introduction of new technologies.

Likely societal impacts

The vast majority of interviewees maintained the view that safety in the European aviation was of paramount importance, but also explained that developments from new technologies would ensure the longevity and relevance of the European aviation industry, whilst also resulting in reductions of gas and noise emissions, which in turn contribute to improved societal impact.

Comparative assessment of the policy options

Assessment of effectiveness

Scientific impacts

Most of stakeholders interviewed for this study supported the view that the scientific impact under Horizon Europe would be best achieved through and institutionalised partnership. Most stakeholders emphasised the importance of a long-term strategy and greater participation of a wider selection of stakeholders. At the same time some stakeholders were of the opinion that the budget should be focussed on higher TRL projects, i.e. levels 3-6, which would ultimately reduce the scientific impact realised from more innovative technologies. Stakeholders interviews also noted that the ability to have more flexibility with regards to programme composition and funding allocation during the partnership would enable resources to be better focussed on more promising technologies, ultimately improving scientific impact.

Economic/technological impacts

Virtually all interviewees considered that an institutionalised partnership was essential if EU sponsorship of aviation related R&I was to have a transformative economic and technological impact on the sector. In the absence of such a framework it transpired, particularly among many of the larger corporations, that their support for the partnership would be substantially reduced. The reason that was most often quoted by stakeholders for supporting a partnership was financial commitment of the industry in this option.

Societal impacts

The vast majority of stakeholders participating in the interview programme considered an institutionalised partnership to be offer the best range of societal benefits, whilst striving for climate neutrality.

Assessment of Coherence

Internal coherence

Stakeholders participating in the interview programme indicated that a future partnership would be able to cooperate more with other initiatives under Horizon Europe to leverage the benefits of technology that is not specific to the aviation sector.

External coherence

A significant proportion of stakeholders mentioned that links with external organisations, such as regulators or the bodies which define the standards, and the synergies drawn from these relationships, are considered as relevant or very relevant topics which need to be addressed by the type of partnerships which is put forwards and reflected in their legal

structure. The ability of each of the options, as described above, to deliver these impacts will be essential to achieve the expected outcomes.

1.3. Open Public Consultation

1.3.1. Characteristics of respondents

There are 191 respondents who have answered (part of) the consultation for the Clean Aviation Partnership. Of these respondents, 55 (29%) were citizens. The largest group of respondents were academic and research institutions (57, 30%) closely followed by businesses 55 respondents (28.80). There were five respondents from business associations (3%). The other respondents were eight representatives of public authorities (4%), three non-governmental organisations (1.57%), or seven others (4%). The overwhelming majority, namely 167 (87%) respondents, have been involved in the on-going research and innovation framework programme, of which 140 respondents (73%) were directly involved in a partnership under Horizon 2020 or its predecessor Seventh Framework Programme.

1.3.2. Characteristics of future candidate European Partnerships – as viewed by respondents to the Clean Aviation initiative

The respondents of this partnership were asked to indicate their views of the needs of the future European Partnerships under Horizon Europe. All 191 respondents answered and mainly indicated that many of these needs were required. The most valued option was making a significant contribution to the EU efforts to achieve climate-related goals (127, 66%).

Views of the respondents in regard to the needs of future European Partnerships under Horizon Europe (N=191)

Stakeholders also noted the presence of regulatory barriers in the context of standards and disruptive technology development and that the lack of global integrated standards

undermines the benefits of R&I activities developed at an EU level, thus affecting European competitiveness.

The Open Public Consultation responses pointed towards several factors that would contribute to a more effective delivery of scientific impacts under an institutionalised partnership.

1.3.3. Relevance of EU level efforts to address problems in relation to Clean Aviation

Respondents were asked to provide their view on the relevancy of research and innovation efforts at EU level to address three types of problems: problems in uptake of Clean Aviation innovations (UI-P), structural and resource problems (SR-P) and research and innovations problems (RI-P).

Views of respondents on relevance of research and innovation efforts at the EU level to address problems in relation to clean aviation

A substantial majority of business organisations, business associations, academic and research institutions, public authorities and EU citizens strongly recognise the impact that long development and innovation cycles and high associated costs of demonstration are having on the growing ecological footprint, whilst all parties also recognise that a future partnership must also make significant contributions to EU global competitiveness.

With regard to the uptake in innovation problems, 76 respondents have indicated that the regulatory framework lagging behind technology developments is very relevant (41%). The lack of consideration of societal and users’ needs was considered as less relevant for research

and innovation efforts at EU level to address, with only 35 respondents indicating this was very relevant (19%)

1.3.4. Horizon Europe mode of intervention to address problems

Respondents were asked to indicate how these challenges could be addressed through Horizon Europe intervention. As shown in Figure 23, just over 45% of respondents indicated that institutionalised partnerships were the best fitting intervention.

Figure 23: Assessment of Horizon Europe intervention

Long-term commitment, demonstration and development of new technology, relevant stakeholders and a common research roadmap were mentioned in support of an institutionalised partnerships

1.3.5. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Respondents were asked how relevant the involvement of actors is in setting a joint long-term agenda to ensure that the proposed European Partnership would meet its objectives. Most respondents indicated that the involvement of industry, (154 respondents; or 82.%) academia (96; 52.%) and Member States and Associated Countries (80; 43.%) is very relevant.

Views of respondents on relevance of actors in setting joint long-term agenda

The responses supported the view that the initiatives should enable the development of a long-term strategy, underpinned by a roadmap, that mainly draws on inputs from industry and academia, with additional inputs from Member States.

1.3.6. Relevance of elements and activities in pooling and leveraging resources

With respect to the relevance of actors in pooling and leveraging resources, such as financial, infrastructure, in-kind expertise etc.), to meet the partnership's objectives, the patterns are very similar. Most of the respondents (13.9; 75%) indicated that industry was very relevant. A large part of respondents also indicated that the involvement of Member States and Associated Countries (96; 52%) and academia (80; 43%) is very relevant.

Among stakeholders responding to the Open Public Consultation there was widespread recognition of the problem of fragmentation and lack of effective coordination of R&I activity, underpinning the case for intervention at the European level.

1.3.7. Relevance of elements and activities for the partnership composition

Respondents were asked about the relevance of Partnership composition, such as flexibility in the composition of partners over time, and involvement of a broad range of partners (including across disciplines and sectors), to reach the partnership's objectives. Ensuring involvement of a broad range of partners has more 'very relevant' answers (99; 55%) than the flexibility in the composition of partners (83; 45%). Overall, 83% of respondents have given flexibility either a score of 4 or 5 (very relevant) which is higher than the 82% who have given the broad range of partners a score of 4 or 5 (very relevant).

Views of respondents on relevance of partnership composition elements

1.3.8. Relevance of implementation of activities

Respondents were asked to provide opinions on relevance of implementation of several activities for meeting objectives of the Clean Aviation. Among activities were listed – joint R&D programme, collaborative R&D projects, deployment and piloting activities, input to regulatory aspects and co-creation of solutions with end-users. Out of 187 respondents, 119 (64%) indicated that collaborative R&I projects are very relevant to ensure that the Partnership would meet its objectives. A Joint R&I programme has also been considered as very relevant by a large number of respondents (112 respondents or 60%). Input to regulatory aspects is seen by the least respondents as very relevant, with 37% (68) of the responses falling in this category, however 72 respondents (40%) have given it a score of 4 on the relevance scale, which indicates that it is still considered as relevant.

No statistical differences were found between the views of citizens and other respondents.

Views of respondents on relevance of implementation of the following activities

In addition, virtually all stakeholders consulted as part of the Open Public Consultation scored the following impacts with high relevance scores: increased industrial leadership and uptake of new technologies; the acceleration of key technologies through selected demonstrators; as well as the creation of high-skilled jobs in the low-carbon economy.

1.3.9. Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Respondents were also asked to assess the relevance of a specific legal structure (funding body) for the candidate European Partnership to achieve several activities. According to Figure 29, the differences across the different categories are not incredibly large. For all but one measure (Implement activities more transparently), over 55% of respondents have selected either 4 or 5 (very relevant) for all the categories. The most respondents indicated that a specific legal structure was ‘very relevant’ to implement its activities more effectively (93 respondents; 50%).

Views of respondents on relevance of a specific legal structure

The Open Public Consultation responses provided further support for the view that a well-defined legal structure of the kind underpinning an institutional partnership could be expected to increase the economic and technological impacts of the initiative.

A substantial majority of business organisations of different sizes, business associations, academic institutions, public authorities and EU citizens considered that such a structure was either relevant or very relevant for achieving more effective and faster implementation of the initiative, increased financial leverage, better links to both regulators and practitioners on the ground, harmonised standards, facilitated synergies with EU/national programmes and facilitated collaboration with other partnerships.

1.3.10. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Respondents were asked to assess the scope and coverage of the Clean Aviation Partnership, based on its inception impact assessment. The clear majority of the respondents indicated that the partnership has the right scope and coverage across all areas, with over 60% of respondents choosing this option. Respondents were the most positive with regard to the type of partners covered (138; 77%), technologies covered (136; 76%) and research areas covered (132; 73%). Across all areas an average of 10% of the respondents indicated that the scope is too narrow.

No statistical differences were found between the views of citizens and other respondents.

Views of respondents on the scope and coverage proposed for the Clean Aviation Partnership

Aside from this multiple choice question, the respondents were also asked to provide any comment that they may have on the proposed scope and coverage for this candidate Institutionalised Partnership. This analysis showed the respondents used this question to talk about low carbon fuel, hybrid electric batteries, impact assessment and the geographical coverage of new technology.

1.3.11. Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

The respondents were also asked if they thought it would be possible to rationalise the candidate European Institutionalised Partnership and its activities, and/or to better link it with other comparable initiatives. 111 respondents (67%) have indicated that they think this is the case.

No statistical differences were found between the views of citizens and other respondents.

The respondents who answered affirmative, were asked which other comparable initiatives it could be linked with. The results show that respondents think the initiative could be linked with comparable initiatives at national level, other European partnerships, including clean hydrogen and traffic management.

In responding to the Open Public Consultation, a majority of stakeholders stated that the legal structure underpinning an institutionalised partnership was either relevant or very relevant to the facilitation of collaboration with other partnerships under Horizon Europe. Support for this view was particularly strong among business organisations with fewer than 250 people, but it was also held by most SMEs, academic and research institutions, public authorities and EU citizens.

A substantial majority in each of the same stakeholder groups confirmed that there would be scope for rationalising the activities of the candidate partnership for Clean Aviation and to link it with other initiatives under Horizon Europe.

1.3.12. Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Respondents were asked to assess the relevance of the candidate European Institutionalised Partnership to deliver on listed impacts. Among societal impacts, a higher number of respondents, namely 134 out of 187 (72%), indicated that the partnership would be ‘very relevant’ for reducing CO₂ emissions. Figure 34 shows that among presented economic/technological impact categories, over 60% of respondents suggest that the partnership would be ‘very relevant’ for increasing industrial leadership in aviation technologies and in uptake of new technologies, for providing highly skilled jobs in industry, and for acceleration of key technologies through selected integrated demonstrators.

Views of respondents on the relevance of the candidate European Institutionalised Partnership to various impacts

Respondents were highly in favour of the potential partnership being used for the advancement of science, to develop new scientific knowledge and capabilities. Impacts that received high relevance scores include increased industrial leadership and uptake of new technologies, the acceleration of key technologies through selected demonstrators and the creation of high-skilled jobs in the low-carbon economy. The reduction in CO₂ emissions and the improvement in public health were also considered as relevant impacts.

1.3.13. Summary of campaigns results for this specific initiative

Three campaigns were identified among respondents that provided answers for the current candidate Partnership. The first campaign includes 17 respondents (campaign #2), the second campaign consists of 19 respondents (campaign #6) and the third campaign consists of 13 respondents (campaign #8).

Overview of responses of the first campaign (campaign #2) (N=17)

Question category	Summary of responses
Research and innovation problems	With exception of one respondent, all respondents from that campaign indicated that the research and innovation efforts at the EU level are ‘very relevant’ to address a listed problem.
Structural and resource problems	With exception of one respondent, all respondents gave a high score (5 ‘very relevant’) for the following categories: “limited collaboration and pooling of resources between public actors and private actors” and “high costs of demonstration of innovative solutions that hinder commercialisation”. Other answer categories received lower and more mixed scores.
Problems in uptake of digital innovations	Respondents views are very mixed across all answer categories. On average, each category received a score of 3.
Preferred Horizon Europe intervention	<p>Institutionalised Partnership was selected by all respondents.</p> <p>When respondents were asked to explain their choice, all of them used the following quote: <i>“Regular calls under Horizon Europe would not deliver the coordinated approach needed for aviation decarbonisation goals. A co-programmed partnership would not have the legal status of an EU body to confer stability, legal certainty and clarity to the partnership. An Institutionalised Partnership has proven effective in ensuring broad participation & financial and legal commitment of all stakeholders, while delivering on ambitious technology Demonstration targets”.</i></p>
Relevance of actors for setting joint long-term agenda	All respondents consider the involvement of industry and academia ‘very relevant’. The involvement of Member States and Associated Countries, on average, scored four. Other answer categories have a lower score, on average.
Relevance of actors for pooling and leveraging resources	All respondents consider the involvement of industry and academia ‘very relevant’. The involvement of Member States and Associated countries, on average, scored four. Other answer categories have a lower score, on average.
Partnership composition	Both categories are considered ‘relevant’ (score 4), on average. However, respondents gave a higher rating to the category “involvement of a broad range of partners, including across disciplines and sectors”.
Implementation of activities	Most respondents gave the highest score to the following activities: “joint R&I programme” and “collaborative R&I projects”. Other categories have more mixed views and a lower score, on average.
Relevance of the legal structure	On average, across all categories, respondents indicated that the legal structure would be ‘relevant’ (score 4). The lowest score (namely, 2.8) was given to the category “ensure better links to practitioners on the ground”.
Scope and coverage of the candidate Partnership	<p>Most respondents consider that listed components of the candidate Partnership have right scope and coverage. The greatest number of respondents that indicated that the scope and coverage are too narrow was for the category “technologies covered”.</p> <p>Respondents were offered an opportunity to provide comments on the proposed scope and coverage of the Institutionalised Partnership. Several of them included the following quote: <i>“Complexity of aviation products and the global-based market and regulations do require any EU effort in improving environmental impact is pursued in parallel and coherently with many other technologies allowing faster in-service introduction, affordability, modularity and simple upgrade of aeronautical products to answer to huge investments EU competitors are doing in those areas to challenge the EU leadership in the Sector”.</i></p>

Question category	Summary of responses
Rationalisation of the candidate Partnership and linking to other initiatives	<p>Out of 17 respondents, 11 (64.71%) consider that it would be possible to rationalise the candidate Partnership and its activities, and/or to better link it with other comparable initiatives.</p> <p>Respondents were asked to explain their answer. Several of respondents that stated that the Partnership and its activities could be rationalised inserted a following quote: <i>“Distinct partnerships needed as stakeholders and processes are different. Lowering emissions need links and synergies with other partnerships. Despite the aeronautical requirements, several building blocks technologies must be developed in common with other sectors and customized to aviation as of basic performances and potential assessed. Among them battery, materials, digitalization, software, big data, industry 4.0, automation, ATM. PPP-I has the strength and role to set-up such strong links”</i>.</p> <p>Almost all respondents that states that it is not possible to rationalise the candidate Partnership and its activities, and/or to better link it with other comparable initiatives inserted the following quote: <i>“The initiatives have distinctly different technology challenges & objectives; while transport partnerships certainly are aligned with one another, the challenges that would be addressed within rail are distinctly.”</i></p>
Societal impact	All respondents consider that the candidate Partnership would be ‘very relevant’ to “reduce CO ₂ emissions”. Other categories received a slightly lower score, but are considered ‘relevant’ by most respondents.
Economic/technological impact	Most respondents consider that the candidate Partnership would be ‘very relevant’ or ‘relevant’ for all suggested impacts.
Scientific impact	Both answer categories are considered ‘very relevant’ by all respondents.

Table 10: Overview of responses of the first campaign (campaign #6) (N=19)

Question category	Summary of responses
Research and innovation problems	All respondents indicated that the research and innovation efforts at the EU level are ‘very relevant’ to address a listed problem.
Structural and resource problems	Most respondents gave a high score (5 ‘very relevant’) for the following categories: “limited collaboration and pooling of resources between public actors and private actors” and “high costs of demonstration of innovative solutions that hinder commercialisation”. Other answer categories received lower and more mixed scores. The lowest score received the category “regulatory barriers in the field of disruptive and digital aviation technology”.
Problems in uptake of digital innovations	The majority of respondents gave a low score (between 2 and 3) across all answer categories.
Preferred Horizon Europe intervention	<p>Institutionalised Partnership was selected by all respondents.</p> <p>When respondents were asked to explain their choice, most of them used the following quote: <i>“Timescales, risks, interdependencies between technologies, integration challenge at aircraft design level require strong coordination. JU = critical mass & strengthens EU aero-industry ecosystem, global leadership & competitiveness. Stable, long-term commitment & collaboration from the innovation chain gives visibility, overcomes inhibitors to increased investment in disruptive R&I & market failure risks. Roadmap aligned with public policy & synergies with national programs”</i>.</p>
Relevance of actors for setting join long-term agenda	All respondents consider the involvement of industry is ‘very relevant’. The involvement of Member States and Associated Countries, as well as, of academia, on average, received a score of 4. Other answer categories have a lower score, on average.

Question category	Summary of responses
Relevance of actors for pooling and leveraging resources	Most respondents consider the involvement of industry and academia is ‘very relevant’. Other answer categories have a lower score, on average.
Partnership composition	Both categories are considered ‘relevant’ (score 4), on average.
Implementation of activities	All respondents gave a high score (either 4 or 5) for all activities, with exception of “co-creation of solutions with end users”. This category received a lower score (3.16), on average.
Relevance of the legal structure	Almost all respondents considered that the legal structure would be ‘very relevant’ for implementation of Partnership activities more effectively, for ensuring better links to regulators, for obtaining more buy-in and long-term commitment from other partners, for facilitating synergies with other EU and national programmes and for facilitating collaboration with other relevant European Partnerships. Other answer categories received a lower score, but all of them are considered ‘relevant’, on average.
Scope and coverage of the candidate Partnership	<p>With exception of one respondent, all listed components of the candidate Partnership are considered to be of right scope and coverage by all respondents.</p> <p>Respondents were offered an opportunity to provide comments on the proposed scope and coverage of the Institutionalised Partnership. Almost all respondents included the following quote: <i>“The Clean Aviation shall serve the green deal policy objectives and contribute to carbon neutrality. Research areas: the Partnership in itself covers the right research areas, but other issues must be tackled in other partnerships: e.g. batteries for aviation in the Battery partnership. Geographical coverage: excellence shall remain the only criterion for the selection of partners”</i>.</p>
Rationalisation of the candidate Partnership and linking to other initiatives	<p>Most respondents (17, 89.47%) consider that it would be possible to rationalise the candidate Partnership and its activities, and/or to better link it with other comparable initiatives.</p> <p>Respondents were asked to explain their answer. Those who stated that it would be possible to rationalise the candidate Partnership included the following quote: <i>“No rationalisation but build bridges with other initiatives. Air transport decarbonisation is too complex for solutions to be developed in CA alone. Upstream cooperation is needed for solutions developed in different sectors to be integrated into aircraft/to ensure new fleets & transport modes can be integrated into ATM. EC should coordinate & support implementation of synergies with ATM, Key Digital Technologies, Batteries, Clean Hydrogen, cybersecurity, AI, 5G, Made in Europe”</i>.</p> <p>Those respondents that considered that it would not be possible to rationalise the candidate Partnership and its activities inserted the following statement: <i>“A dedicated, strong and stable partnership embracing all relevant research and innovation actors not only from within the aeronautics sector, but where appropriate newcomers with key technologies from other sectors joining in the effort is a condition precedent for success. This partnership must maximize synergies with other partnerships such as ECSEL, SESAR and FOF to ensure coordination and increase impact”</i>.</p>
Societal impact	All respondents consider that all listed categories are ‘very relevant’.
Economic/technological impact	With exception of one answer in one category, all respondents consider that the candidate Partnership would be ‘very relevant’ for all suggested impacts.
Scientific impact	All respondents consider that all listed categories are ‘very relevant’.

Annex 3

Who Is Affected And How?

1. PRACTICAL IMPLICATIONS OF THE INITIATIVE

The proposed European Partnership on Clean Aviation focuses on areas where there is a demonstrable advantage in acting at the EU-level due to complexity and size of the industry, the significant societal impact, and scope of the efforts needed for the EU as a whole to achieve the intended objectives.

The partnership will aim at contributing significantly to meeting the intermediate Green Deal targets for 2030 and achieving climate neutrality for aviation by 2050. It will bring together the public, academic and private sectors around this common goal.

The coordinated involvement of the private sector in this context is crucial in designing a strategic research and innovation agenda with concrete targets, milestones and deliverables in line with Green Deal requirements. The private sector, by having a central role in the proposed Clean Aviation Partnership, will benefit from the long-term vision and financial certainty required for its businesses and industries to grow and to strengthen the competitiveness of the EU Clean Aviation value chain (notably SMEs);

The public sector involvement in the partnership needs to ensure adequate policy support to facilitate the market uptake of the partnership's technical achievements.

Academia and the scientific community play a pivotal role in strengthening and integrating scientific capacity to accelerate the development and improvement of advanced clean aviation technologies and create a pipeline of innovative solutions to be picked up by the partnership.

Civil society as a whole is mainly affected by the climate change issue. The proposed Clean Aviation Partnership provides the right framework to accelerate the greening of aviation.

Finally, in an increasingly globalized and interlinked world, governments are required to enhance their role in the fight against climate change. New evidence on this issue should be incorporated in every level of policy-making and in every sector. Governments are responsible for the development, implementation and enforcement of environmental clean energy and climate change regulation.

2. SUMMARY OF COSTS AND BENEFITS

For the preferred option

<i>I. Overview of Benefits (total for all provisions) – Preferred Option</i>		
<i>Description</i>	<i>Estimation (quantitative or qualitative)</i>	<i>Comments</i>
<i>Direct benefits</i>		
Implement Green Deal for aviation	Major contribution to climate neutrality of aviation by 2050, as key policy of the European Union. Significant improvements in pollution related health issues.	Considering the world-wide impact of the European aeronautics industry, the benefits would have world-wide effects

	Reduction of noise around airports	
Increased competitiveness of the European aeronautics industry	Maintain employment. In total, aviation currently supports 12.2 million European jobs.	The technological advancements would significantly increase the quality of the European aircraft helping to maintain the European leadership position in this sector.
The alignment of European, national and company research efforts on basis of a single Strategic Research and Innovation Agenda would significantly increase the impact of aviation research	Increased effectiveness and efficiency of the European research in aviation.	
Better integrated research and innovation landscape	<p>Early involvement of EASA reducing the long research and innovation life cycle in the sector</p> <p>Establish structural links with other sectors (such as batteries and hydrogen) leading to cross sectoral benefits</p> <p>Increased cooperation between European companies across the whole value chain in aviation.</p>	
Indirect benefits		

II. Overview of direct and indirect costs – Preferred option							
		Citizens/Consumers		Businesses		Administrations	
		One-off	Recurrent	One-off	Recurrent	One-off	Recurrent
Management/ Administrative costs	Direct costs				170		170
	Indirect costs			4	790	4	790
Personnel costs	Direct costs			0	2200	0	2200
	Indirect costs			4	105	4	105
Coordination costs (or transaction costs)					110		110

Budget expenditure/ investment costs				45		45	
---	--	--	--	----	--	----	--

TOTAL (kEUR)

6,854.96

The table assumes a similar Office size for the Horizon Europe Clean Aviation partnership as the current Horizon 2020 Clean Sky 2 Joint Undertaking. The table is filled on basis of the actual 2019 administrative budgetary payments of the Clean Sky 2 Joint Undertaking. Since according to the Clean Sky 2 basic act 50% of the admin cost are covered by the private members, the figures were equally split between the “Businesses” and “Administrations” columns.

Thus the “business” part represents what’s paid by industry and the “administration” part what’s paid by EC funds.

In particular please find here after examples of categories of costs included:

Under the personnel category:

- Direct: salaries (interim and SNEs included)
- Indirect (recruitment, training fees, health insurance, transport)

coordination:

- Direct (meetings organisation; SCICOM experts)
- Indirect: N/A

Investment:

- Indirect: audio-visual equipment for meeting rooms, photocopier, laptop

Management:

- Direct: missions, experts reviewers
- Indirect: building, external consultants, communication (publications, events), telecommunications, IT operational expenses (external IT support, connections, systems etc)

REFIT Cost savings table

Not applicable for the proposed Clean Aviation Partnership. The initiative will benefit from the existing organisation/structure (e.g. the Programme Office) already in place for the CS2 JU. There are no additional regulatory costs associated, and no specific simplification measures apply in this case.

Annex 4 Analytical Methods

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines⁷ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This is complemented by integrating the **conditions and selection criteria for European Partnerships**, as well as requirements for setting up Institutionalised Partnerships.⁸

1. OVERVIEW OF THE METHODOLOGIES EMPLOYED

In terms of **methods and evidence used**, the set of impact assessments for all candidate Institutionalised European Partnerships draw on an external study covering all initiatives in parallel to ensure a high level of coherence and comparability of analysis.⁹

All impact assessment mobilised a mix of qualitative and quantitative data collection and analysis methods. These methods range from desk research and interviews to the analysis of the responses to the Open Consultation, stakeholder analysis and composition/portfolio analysis, bibliometric/patent analysis and social network analysis, and a cost-effectiveness analysis.

The first step in the impact assessment studies consisted in the definition of the context and the problems that the candidate partnerships are expected to solve in the medium term or long run. The main data source in this respect was desk research. This includes grey and academic literature to identify the main challenges in the scientific and technologic fields and in the economic sectors relevant for the candidate partnerships, as well as the review of official documentations on the policy context for each initiative.

In the assessment of the problems to address, the lessons to be learned from past and ongoing partnerships were taken into account, especially from relevant midterm or ex-post evaluations.

The description of the context of the candidate institutionalised European Partnerships required a good understanding of the corresponding research and innovation systems and their outputs already measured. Data on past and ongoing Horizon 2020 projects, including the ones implemented through Partnerships, served as basis for descriptive statistic of the numbers of projects and their respective levels of funding, the type of organisations participating (e.g. universities, RTOs, large companies, SMEs, public administrations, NGOs, etc.) and how the funding was distributed across them. Special attention was given to analysing the participating countries (and groups of countries, such as EU, Associated Countries, EU13 or EU15) and industrial sectors, where relevant. The sectoral analysis required enriching the eCORDA data received from the European Commission services with sector information extracted from ORBIS, using the NACE codification up to level 2. These data enabled the identification of the main and, where possible, emerging actors in the

⁷ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

⁸ A pivotal element of the present analysis is the so-called two-step 'necessity test' for European Partnerships, used to establish: step 1) the need for a partnership approach in the first place, followed by step 2) a justification for the form of Institutionalised Partnership. The necessity test is described in Annex 6. This impact assessment focuses on the second step of the test.

⁹ Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe

relevant systems, i.e. the organisations, countries and sectors that would need to be involved (further) in a new initiative.

A Social Network Analysis was performed by the contractors using the same data. It consisted in mapping the collaboration between the participants in the projects funded under the ongoing R&I partnerships. This analysis revealed which actors – broken down per type of stakeholders or per industrial sector – collaborate the most often together, and those that are therefore the most central to the relevant research and innovation systems.

The data provided finally served a bibliometric analysis run by the contractor aimed at measuring the outputs (patents and scientific publications) of the currently EU-funded research and innovation projects. A complementary analysis of the Scopus data enabled to determine the position and excellence of the European Union on the international scene, and identify who its main competitors are, and whether the European research and innovation is leading, following or lagging behind.

A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options.

The conclusions drawn from the data analysis were confronted to the views of experts and stakeholders collected via three means:

- The comments to the inception impact assessments of the individual candidate institutionalised European Partnerships;
- The open public consultation organised by the European Commission from September to November 2019;
- The interviews (up to 50) conducted by each impact assessment study team conducted between August 2019 and January 2020 (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others).

The views of stakeholders (and experts) were particularly important for determining the basic functionalities (see further below) that the future partnerships need to demonstrate to achieve their objectives as well as their most anticipated scientific, economic and technological, and societal impacts. The interviews allowed more flexibility to ask the respondents to reflect about the different types of European Partnerships. Furthermore, as a method for targeted consultation, it was used to get insights from the actors that both the study teams and the European Commission deemed the most relevant. For the comparative assessment of impacts, the external contractors confronted the outcomes of the different stakeholder consultation exercises to each other with a view of increasing the validity of their conclusions, in line with the principles of triangulation.

Annex 2 includes also the main outcomes of the stakeholder consultation exercises.

2. METHOD FOR ASSESSING THE EFFECTIVENESS, EFFICIENCY AND COHERENCE OF EACH OPTION - THE USE OF FUNCTIONALITIES

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has been adapted to introduce “**key functionalities needed**”

– so as to link the intended objectives of the candidate European Partnerships and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1 in the main body of the impact assessment). In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options. It also allows for a structured comparison of the options as regards their effectiveness, efficiency and coherence, and also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)¹⁰.

Figure 3 Overview of key functionalities of each form of implementation of European Partnerships

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
Type and composition of actors (including openness and roles)				
<u>Partners:</u> N.A., no common set of actors that engage in planning and implementation <u>Priority setting:</u> open to all, part of Horizon Europe strategic planning <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> core of national funding bodies or governmental research organisations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> limited, according to national rules of partner countries	<u>Partners:</u> National funding bodies or governmental research organisation <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations
Type and range of activities (including additionality and level of integration)				
<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions <u>Additionality:</u> no additional activities and investments outside the funded projects <u>Limitations:</u> No systemic approach beyond individual actions	<u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake <u>Additionality:</u> Activities/investment s of partners, national funding <u>Limitations:</u> Limited systemic approach beyond individual	<u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake <u>Additionality:</u> National funding <u>Limitations:</u> Scale and scope depend on the participating programmes, often	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach <u>Additionality:</u> National funding	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds). <u>Additionality:</u> Activities/investments of partners/ national

¹⁰ The criterion on the ex-ante demonstration of partners’ long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
	actions.	smaller in scale		funding
Directionality				
<u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years. <u>Limitations:</u> Fully taking into account existing or to be developed SRIA/roadmap	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Input to FP annual work programme drafted by partners, finalised by COM (comitology) Objectives and commitments are set in the contractual arrangement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the Grant Agreement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the legal base.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM (veto-right in governance) Objectives and commitments are set in the legal base.
Coherence: internal (Horizon Europe) and external (other Union programmes, national programmes, industrial strategies)				
<u>Internal:</u> Between different parts of the Annual Work programme can be ensured by COM <u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Limited synergies with other Union programmes and industrial strategies If MS participate, with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with other Union programmes and industrial strategies If MS participate, with national/regional programmes and activities

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made in comparison to the baseline. Therefore, for each of the above criteria, the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. When relevant, this estimation also includes the costs/benefits of discontinuing existing implementation structures. The policy options are then scored compared to the baseline with a + and – system along a two-point scale, to indicate limited (+ or -) or high (++ or --) additional/lower performance compared to the baseline. When a policy option is scored 0, this means that its impact is expected to be roughly equal to the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific,

economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options¹¹.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach¹² to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account¹³. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs of each candidate initiative.¹⁴ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership the costs of preparation and implementation

¹¹ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

¹² For further details, see Better Regulation Toolbox # 57.

¹³ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

¹⁴ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

increase only marginally compared to the baseline (<1%),¹⁵ but lead to an additional R&I investment of at least the same amount than the Union contribution¹⁶ (efficiency of 98% for the overall investment).

- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2-3 times the Union contribution¹⁷. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).¹⁸
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution¹⁹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution²⁰. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs

Annual Work Programme preparation	0		↑		
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑

¹⁵ Specifically, some additional set-up costs linked for example to the creation of a strategic research and innovation agenda (SRIA) and additional running costs linked with the partners role in the creation of the annual work programmes and the Commission's additional supervisory responsibilities. A CPP will have lower overall costs than each of the other types of European Partnership, as it will function with a smaller governance and implementation structure than will be required for a Co-Funded Partnership or an Institutionalised Partnership and – related to this – its calls will be operated through the existing Horizon Europe agencies and RDI infrastructure and systems.

¹⁶ Minimum contributions from partners equal to the Union contribution.

¹⁷ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

¹⁸ These costs reflect set-up costs and additional running costs for partners, and the Commission, of the distributed, multi-agency implementation model.

¹⁹ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

²⁰ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC	0				↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**). In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

3. METHOD FOR IDENTIFYING THE PREFERRED OPTION – THE SCORECARD ANALYSIS

For the **identification of the preferred option**, a scorecard analysis is used to build a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

This scorecard approach also relies on a standard cost model developed for the external study supporting the impact assessment, as illustrated in **Error! Reference source not found.** Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**). In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

These costs essentially refer to the administrative, operational and coordination costs of the various options. The figure shows how the scoring of costs range from a value of 0, in case an option does not entail any additional costs compared to the baseline (traditional calls), to a score of (-) for options introducing limited additional costs relative to the baseline and a score of (- -) when substantial additional costs are expected in comparison with the baseline. Should the costs of a policy option be lower than those of the baseline, (+) and (+ +) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. A score of + is therefore assigned for **cost-efficiency** to the Co-Programmed and Co-Funded options,

a score of zero to the Article 185 option and a score of (-) for the Article 187 Institutionalised Partnership policy option²¹.

Figure 5: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Co- funded	Option 3a: Institutionalised 185	Option 3b: Institutionalised 187
Administrative, operational and coordination costs	0	(0)	(-)	(- -)	(- -)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. <i>cost- efficiency</i>)	0	(+)	(+)	(0)	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared to baseline; score (- -) = substantial additional costs compared to baseline. ; score (+) = lower costs compared to baseline

²¹ The baseline (traditional calls) is scored 0, as explained above.

1. Can the Union act? What is the legal basis and competence of the Unions' intended action?
1.1 Which article(s) of the Treaty are used to support the legislative proposal or policy initiative?
<p>This proposal is based on (1) Article 185 TFEU which stipulates that in implementing the multiannual framework programme, the EU may make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; and (2) Article 187 TFEU according to which the EU may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes (both articles are under Title XIX of the TFEU - Research and Technological Development and Space).</p> <p>The proposal aims to implement Article 8 of the Commission proposal for Horizon Europe - the future EU research and innovation (R&I) programme for 2021-2027, according to which, “<i>European Partnerships shall be established for addressing European or global challenges only in cases where they will more effectively achieve objectives of Horizon Europe than the Union alone and when compared to other forms of support of the Framework programme</i>”. The Horizon Europe proposal has received the political agreement of the Council and the European Parliament.</p>
1.2 Is the Union competence represented by this Treaty article exclusive, shared or supporting in nature?
<p>Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the European Union can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas.</p> <p><i>Subsidiarity does not apply for policy areas where the EU has exclusive competence as defined in Article 3 TFEU²². It is the specific legal basis which determines whether the proposal falls under the subsidiarity control mechanism. Article 4 TFEU²³ sets out the areas where competence is shared between the Union and the Member States. Article 6 TFEU²⁴ sets out the areas for which the EU has competence only to support the actions of the Member States.</i></p>

²² <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E003&from=EN>

²³ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E004&from=EN>

²⁴ <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:12008E006:EN:HTML>

2. Subsidiarity Principle: Why should the EU act?

2.1 Does the proposal fulfil the procedural requirements of Protocol No 2²⁵:

- Has there been a wide consultation before proposing the act?
- Is there a detailed statement with qualitative and, where possible, quantitative indicators allowing an appraisal of whether the action can best be achieved at Union level?

This proposal and the accompanying impact assessment were supported by a wide consultation of stakeholders, both during the preparation of the Horizon Europe proposal and - later on, all the candidates for European Partnerships. Member States were consulted via the Shadow Strategic configuration of the Horizon Europe Programme Committee. On candidates for institutionalised Partnerships based on Article 185/187 of the TFEU, an Open Public Consultation (OPC) was held between 11 September and 6 November 2019. Over 1 600 replies were received. In addition, targeted consultation activities were undertaken to prepare the present impact assessment. In particular, for each of the candidate partnerships, an external consultant interviewed a representative sample of stakeholders. The need for EU action as well as its added value were covered in those interviews.

The explanatory memorandum and the impact assessment (horizontal part, Section 3) contain a dedicated section on the principle of subsidiarity, as explained in question 2.2 below.

2.2 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the conformity with the principle of subsidiarity?

The impact assessment accompanying the proposal features a horizontal part on relevant common elements to all the candidate partnerships, including the conformity of the proposed initiative with the principle of subsidiarity (Section 3). Moreover, the individual assessments of each candidate partnership include additional details on subsidiarity, touching in particular on the specificities of a candidate partnership that could not be adequately reflected in the horizontal part of the impact assessment. This will also be reflected in the explanatory memorandum.

2.3 Based on the answers to the questions below, can the objectives of the proposed action be achieved sufficiently by the Member States acting alone (necessity for EU action)?

National action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term treaty objectives, to deliver on the EU's strategic policy priorities (including the climate and energy goals set out in the Paris Agreement, and the European Green Deal), and to contribute to tackling global challenges and meeting the Sustainable Development Goals (SDGs).

²⁵ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12016E/PRO/02&from=EN>

(a) Are there significant/appreciable transnational/cross-border aspects to the problems being tackled? Have these been quantified?

The thematic areas covered by the candidate partnerships feature a series of challenges in terms of cross-border/transnational aspects, need to pool resources, need for a critical mass to meet intended policy objectives, need to coordinate different types of actors (e.g. academia, industry, national and regional authorities) across different sectors of the economy and society, which cannot be tackled to the same degree by Member States alone. This is particularly true for the research and innovation (R&I) dimension of the proposed initiative: the importance of a multi-centre and interdisciplinary approach, cross-country data collection and research, and the need to develop and share new knowledge in a timely and coordinated manner to avoid duplication of efforts are key to achieve high quality results and impact. The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide extensive qualitative and quantitative evidence on the above points. In addition, Sections 1 and 2 of the individual impact assessments on the candidate partnerships include more detail on the necessity to act at EU-level in specific thematic areas. Finally, it is worth noting that not all Member States have the same capacity or R&I intensity to act on these challenges. As the desired policy objectives can be fully achieved only if the intended benefits are widespread across the Member States, this requires action at the EU-level.

(b) Would national action or the absence of the EU level action conflict with core objectives of the Treaty²⁶ or significantly damage the interests of other Member States?

As per Article 4(3) TFEU, national action does not conflict with core objectives of the Treaty in the area of R&I. The absence of EU level action in this area would however prevent the achievement of core objectives of the Treaty. Indeed, national action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives on e.g. competitiveness, to deliver on the EU's strategic policy priorities, and to contribute to tackling global challenges and meet the Sustainable Development Goals (SDGs).

(c) To what extent do Member States have the ability or possibility to enact appropriate measures?

As foreseen by Article 4(3) TFEU, this proposal does not hamper Member States' ability to enact appropriate measures in the field of R&I. However, the scale and complexity of the policy objectives pursued by the present initiative cannot be fully addressed by acting at national level alone.

(d) How does the problem and its causes (e.g. negative externalities, spill-over effects) vary across the national, regional and local levels of the EU?

As described in the horizontal part of the impact assessment accompanying the present proposal, several problems (e.g. on competitiveness, global challenges, demographic change) and their underlying causes affect the EU as a whole rather than individual Member States.

²⁶ https://europa.eu/european-union/about-eu/eu-in-brief_en

<p>Where important differences between Member States are present, these are described in Sections 1 and 2 of the individual impact assessments.</p>
<p>(e) Is the problem widespread across the EU or limited to a few Member States?</p>
<p>The problem of coordinating R&I efforts in the thematic areas covered by the candidate partnerships affects all Member States, albeit to different degrees. However, from a general EU perspective, available evidence shows that the EU as a whole needs to step up efforts and investments in thematic areas that are crucial to tackle present and future policy challenges on several fronts, e.g. ageing population, global technological trends, and climate change to name a few. The way these problems affect the EU and its Member States is described in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual impact assessments.</p>
<p>(f) Are Member States overstretched in achieving the objectives of the planned measure?</p>
<p>As indicated in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual assessments, the sheer scale, speed and scope of the needed support to R&I would overstretch national resources, without guaranteeing the achievement of the intended objectives. Acting at EU-level would achieve greater impact in a more effective and efficient manner.</p>
<p>(g) How do the views/preferred courses of action of national, regional and local authorities differ across the EU?</p>
<p>No specific differences between the views of national, regional and local authorities emerged from the stakeholder consultation.</p>
<p>2.4 Based on the answer to the questions below, can the objectives of the proposed action be better achieved at Union level by reason of scale or effects of that action (EU added value)?</p>
<p>EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national initiatives in the same area.</p>
<p>(a) Are there clear benefits from EU level action?</p>
<p>Quantitative and qualitative evidence of the benefits of EU level action are available in the interim evaluation of Horizon 2020 and in the impact assessment of Horizon Europe, among others. An analysis of the emerging challenges in each thematic areas, of the EU's competitive positioning, as well as feedback gathered from different types of stakeholders for the present impact assessment indicate that EU level action remains appropriate also for the</p>

present proposal. In addition, the benefits of acting at EU level have been illustrated by the success and the impact achieved by the predecessors to the proposed initiative.

(b) Are there economies of scale? Can the objectives be met more efficiently at EU level (larger benefits per unit cost)? Will the functioning of the internal market be improved?

EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. This is the case both in terms of effectiveness in achieving intended policy objectives, but also in terms of efficiency. Positive impact is also visible in terms of competitiveness: recent data on EU funded R&I activities indicate that EU-funded teams grow 11.8% faster and are around 40% more likely to be granted patents or produce patents applications than non-EU funded teams. Efficiency gains are also visible in terms of dissemination of results to users beyond national borders, including SMEs, and citizens. EU funded R&I is more effective in leveraging private investment. Finally, there are clear additionality benefits (i.e. EU R&I funding does not displace or replace national funding), as the EU focuses on projects that are unlikely to be funded at national or regional level. Overall, this is beneficial to the functioning of the internal market in several respects, including human capital reinforcement through mobility and training, the removal of barriers to cross-border activity for economic players including SMEs, easier access to finance and to relevant knowledge and research, and increased competition in the area of R&I.

(c) What are the benefits in replacing different national policies and rules with a more homogenous policy approach?

A homogeneous policy approach in the various thematic areas covered by the present proposal would reduce fragmentation and increase efficiency and effectiveness in meeting the intended policy objectives. Indeed fragmentation, persisting barriers in the internal market and differences in the resources available to Member States are some of the key problems that stand in the way of fully achieving the intended policy objectives and reaching the required critical mass to obtain tangible results. Specific detail on how these issues differ in each thematic area are illustrated in Sections 1 and 2 of the individual impact assessments, so as to reflect the specificities of each case.

(d) Do the benefits of EU-level action outweigh the loss of competence of the Member States and the local and regional authorities (beyond the costs and benefits of acting at national, regional and local levels)?

The proposed initiative does not lead to a loss of competence of the Member States. In fact, the proposed initiative should be seen as complementary and reinforcing national and sub-national initiatives in the same area. Previous quantitative and qualitative assessments of Horizon Europe and Horizon 2020 have shown that the proposed EU-level action do not displace national ones and tend to concentrate on initiatives that would not have been funded by the Member States themselves, or would not have reached the same scale and ambition without EU-level intervention, due to their complexity and trans-national nature.

(e) Will there be improved legal clarity for those having to implement the legislation?

Yes. The proposed initiatives will be implemented in line with the Horizon Europe single set of rules for participation; this will ensure increased clarity and legal certainty for end beneficiaries, other stakeholders and programme administrators. It will also reduce the administrative burden for beneficiaries, and for the Commission services. In addition, the accessibility and attractiveness of the broader Horizon Europe programme, in particular for applicants with limited resources, would be sustained.

3. Proportionality: How the EU should act

3.1 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the proportionality of the proposal and a statement allowing appraisal of the compliance of the proposal with the principle of proportionality?

The principle of proportionality underpins the entire analysis of the candidate partnerships. Specifically, the analysis included in the accompanying impact assessment is structured along the following logic: 1. Justification of the use of a partnership approach in a given area (including considerations on additionality, directionality, link with strategic priorities) instead of other forms of intervention available under Horizon Europe; 2. If the partnership approach is deemed appropriate, proportionality considerations guide the assessment of which type of partnership intervention (collaborative calls, co-programmed, co-funded or institutionalised partnership) is most effective in achieving the objectives. This will also be reflected in the explanatory memorandum.

3.2 Based on the answers to the questions below and information available from any impact assessment, the explanatory memorandum or other sources, is the proposed action an appropriate way to achieve the intended objectives?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the present proposal leaves full freedom to the Member States to pursue their own actions in the policy areas concerned. This will also be reflected in the explanatory memorandum.

(a) Is the initiative limited to those aspects that Member States cannot achieve satisfactorily on their own, and where the Union can do better?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments.

(b) Is the form of Union action (choice of instrument) justified, as simple as possible, and

coherent with the satisfactory achievement of, and ensuring compliance with the objectives pursued (e.g. choice between regulation, (framework) directive, recommendation, or alternative regulatory methods such as co-legislation, etc.)?

For each of the candidate partnerships, the analysis carried out in the accompanying impact assessment has explored several options for implementation. A comparative assessment of the merits of each option also included an analysis of the simplicity of the intervention, its proportionality and effectiveness in achieving the intended objectives. This is reflected in the fact that a tailored approach has been suggested for each candidate partnership, ranging from looser forms of cooperation to more institutionalised ones, depending on the intended policy objectives, specific challenges, and desired outcome identified in each case.

(c) Does the Union action leave as much scope for national decision as possible while achieving satisfactorily the objectives set? (e.g. is it possible to limit the European action to minimum standards or use a less stringent policy instrument or approach?)

The proposed approach leaves full freedom to the Member States to pursue their own actions in the policy areas covered by the present proposal.

(d) Does the initiative create financial or administrative cost for the Union, national governments, regional or local authorities, economic operators or citizens? Are these costs commensurate with the objective to be achieved?

The proposed initiatives create financial and administrative costs for the Union, national governments and, depending on the chosen mode of implementation, for regional and local authorities. In addition, economic operators and other stakeholders potentially involved in the candidate partnerships will also incur some costs linked to implementation. The financial cost of the proposed initiative is covered under the Horizon Europe programme. Its exact amount is still subject to political decision. As regards the candidate partnerships and the different modes of implementation (co-programmed, co-funded, institutionalised), the relevant costs and benefits are assessed in the individual impact assessments covering each candidate partnership. The additional administrative costs of implementation via partnerships are limited, when compared to the administrative costs of implementation through traditional calls. As indicated by comparable experience with previous initiatives and in feedback provided by a variety of stakeholders, these costs are expected to be fully justified by the benefits expected from the proposed initiative. Where available, additional details on costs are provided in Annex 3 of the impact assessment.

(e) While respecting the Union law, have special circumstances applying in individual Member States been taken into account?

Where relevant, differences between Member States in capacity and stage of advancement of R&I in specific thematic areas have been taken into account in the individual impact assessments.

Annex 6 Additional background information

1. BACKGROUND INFORMATION FOR ALL INITIATIVES

1.1. Selection criteria of European Partnerships

Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

The necessity test for a European Partnership (as set out in the Horizon Europe regulation) has two levels:

1. **The justification for implementing a priority with a European Partnership** to address Horizon Europe and EU priorities. This is linked to demonstrating that a European Partnership can produce added value beyond what can be achieved through other framework programme modalities, notably traditional calls in the work programmes (Option 0 – Baseline).
2. **The justification for the use of the form of Institutionalised Partnership:** Once it has been demonstrated that a partnerships approach is justified, co-programmed and/or co-funded forms are considered for addressing the priorities as they are administratively lighter, more agile and easier to set-up (Options 1 and/or 2). As Institutionalised Partnerships require setting up a legal framework and the creation of a dedicated implementation structure, they have to justify higher set-up efforts by demonstrating that it will deliver the expected impacts in a more effective and efficient way, and that a long-term perspective and high degree of integration is required (Option 3).

The outcomes of the ‘necessity test’ is presented together with the preferred option.

Figure 5 Horizon Europe selection criteria for the European Partnerships

Common selection criteria & principles	Specifications
1. More effective (Union added value) clear impacts for the EU and its citizens	Delivering on global challenges and research and innovation objectives
	Securing EU competitiveness
	Securing sustainability
	Contributing to the strengthening of the European Research and Innovation Area
	Where relevant, contributing to international commitments
2. Coherence and synergies	Within the EU research and innovation landscape
	Coordination and complementarity with Union, local, regional, national and,

Common selection criteria & principles	Specifications
	where relevant, international initiatives or other partnerships and missions
3. Transparency and openness	Identification of priorities and objectives in terms of expected results and impacts
	Involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness
	Clear modalities for promoting participation of SMEs and for disseminating and exploiting results, notably by SMEs, including through intermediary organisations
4. Additionality and directionality	Common strategic vision of the purpose of the European Partnership
	Approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level
	Demonstration of expected qualitative and significant quantitative leverage effects, including a method for the measurement of key performance indicators
	Exit-strategy and measures for phasing-out of the programme
5. Long-term commitment of all the involved parties	A minimum share of public and/or private investments
	In the case of institutionalised European Partnerships, established in accordance with article 185 or 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments

1.2. Overview of potential functions for a common back office among Joint Undertakings

Functions	Current situation	Option of common back office	Comments
Organising calls for grant and proposal evaluations	Each JU organises this independently.	A central organisation of evaluation, logistics, contracting evaluators, managing the data of the evaluation results Central database of potential evaluators with domain expertise in thematic areas of partnerships	The evaluations would still need to be supervised by the Scientific staff of the individual Joint Undertakings (consensus meetings of expert evaluators etc)
Human Resources related matters	Each JU has own HR policy and resources Substantial resources spent on recruitment in some JUs Some HR facilities are procured from external contractors Some JUs have a Service Level Agreement with EC for HR	More generic resources and expertise for HR matters More consistency in HR policy Shared HR investment for specialised expertise (IP and legal)	Ensuring consistency with EC HR policies is already in place
Financial	Each JU conducts own financial	Financial management	Simplifies the harmonisation of

management	contract management; differences between JUs Each JU is audited separately. Auditing at project level more frequent than in other Horizon 2020 parts and outsourced by JUs thus differences ECA: too many audits on JUs	by one core team of financial staff Would reduce the number of interfaces for audits and simplifies the auditing of the all JUs Harmonisation of project auditing	financial management across JUs in line with Horizon Europe
Communication (internal and external)	Each JU has a separate communication strategies, team and resources	A common back-office can support activities such as event organisation, dissemination of results, setting up website communication Can help create a more visible European Partnership brand	A considerable share of communication activity is partnership specific (addressing particular target groups, synthesising project results) however there are generic communication activities that can be shared Needs to avoid duplication of efforts
Data management on calls, project portfolios, information on project results	Most JUs but not all use e-Corda for project data Overall IT integration of JUs still difficult	Harmonised data management Reduction of IT systems and support that is procured	This will need to happen regardless of the common back office but will likely be more smooth if managed centrally

2. COVID-19 IMPACT ON AVIATION AND AVIATION RESEARCH

2.1. The overall impact

At European level, and before the COVID-19 outbreak, Eurocontrol estimated that Europe would see 16.2 million flights in 2040, 53% more than 2017 – that is 1.9% average annual growth per year over the 2017-2040 period, a rather slower growth rate than before 2008.

On 22 March 2020, the European traffic was 75% less than on the same day last year. The current and post COVID-19 economic situation, with the connected national restrictions on travel has led to a situation where the air traffic is about 10% in comparison to before the crisis.

Initial reports suggest that coronavirus could wipe out up to USD 113 billion in worldwide airline revenues in 2020. This figure is nearly half of the five-year (2015-2019) cumulative profit of the airline industry, estimated at USD 269 billion – the best in airline history. The US government approved USD 2 trillion coronavirus stimulus and part of it will go to US airlines and US aircraft manufacturers (i.e. Boeing).

While previous pandemic outbreaks have demonstrated the resilience of the sector to bounce back relatively swiftly²⁷ it must be recognised that the COVID-19 crisis is of unprecedented scale and magnitude. The consequences of the COVID-19 pandemic may be felt strongly and long term in aviation, with reduced customer demand, shrinking civil

²⁷

<https://www.iata.org/en/iata-repository/publications/economic-reports/what-can-we-learn-from-past-pandemic-episodes/>

aircraft fleets and the manufacturing industry confronted with cancelled orders instead of overflowing order-books.

The industrial sector is not expecting a full recovery²⁸ before 2025-30.

2.2. Impact on research and innovation

The impact of coronavirus to the economy will also be felt in EU aviation R&I – hopefully in the short-term only. Many companies, in view of the expected downturn in aviation, have already announced plans to cut costs (including research activities). Research and market decisions, as well as the financial investments, have long-term impact in aviation. Preparation of new transformative R&I programmes entails big financial and technological risk, without any immediate market reward.

The Clean Sky 2 JU and main private partners reported during the Clean Sky 2 Governing Board meeting that COVID-19 and related health measures, already caused a 4-6 months delay across the board for the on-going research projects. It is foreseen that cuts in research and innovation (R&I) investments in the private sector will range from 25% to 40% in 2020.

2.3. Impact on deployment of research results

The COVID-19 crisis may delay the market entry of green technologies.

For airlines to invest in cleaner and more efficient aircrafts, four elements should be timely aligned: healthy air-traffic demand (high regional and/or global growth, limited geopolitical instabilities), high airlines profitability (over a number of years), low interest rates and high fuel prices. At times of high uncertainty (i.e. coronavirus, trade wars, increased geopolitical instabilities), these four parts of the “invest-in-more-efficient-aircrafts” equation do not add up. As a consequence, aircraft makers do not easily decide to invest EUR 20-40 billion for developing a new aircraft.

In addition to the nearly complete halt of air traffic, the recent (March 2020) drop in oil-prices due to coronavirus, exposed airlines to billions of euro of fuel hedging losses. These hundreds of billions of euro in total losses for airlines due to coronavirus will have a direct impact to ongoing as well as future orders and decisions. This makes the investment in aviation R&I even more urgent and more financially demanding. That’s why the limited available European R&I investments should have clear ambitious and achievable objectives.

2.4. Research focus on health

Aviation, climate and economy are all inherently global. It contributes to European prosperity, national security, European social integration, single market and provides EU leaders the financial strength to absorb external shocks (e.g. financial crisis, coronavirus) and invest in climate neutrality and social challenges.

However, aviation has contributed as a carrier for the fast spread of the coronavirus from Asia to the rest of the world – as happened in the past with other infectious diseases (avian flu, SARS, etc). The COVID-19 crisis may thus also lead to new research efforts

²⁸ <https://www.icao.int/sustainability/Pages/Economic-Impacts-of-COVID-19.aspx>

in turning civil aircraft into early warning systems and for collecting health data on planes. This area can however be tackled by collaborative research outside the initiative.

This priority should follow a holistic approach between technologies and operations, at airport and aircraft levels. While, it will build on existing WHO, ICAO, and ACI recommendations on airport preparedness guidelines for outbreaks of communicable diseases, it will also focus on a clean-sheet technological approach to air cabin quality.

The objectives may include:

- breakthrough cost-effective air-cabin circulation technologies that will increase the effectiveness of cabin air circulation, before being filtered by HEPA filters;
- Real-time measurement technologies for pathogens should be developed, validated and tested in real aircraft environment;
- Air-circulation-altering devices for specific rows in the aircraft cabin, or for the whole aircraft should be explored as mitigating measures, especially for long-haul flights;
- Technologies already used in hospitals, based on ultraviolet light UV-C to sterilize rooms against viruses, including superbugs, should be further exploited and become cost-effective at airport and aircraft levels;

Aircraft technologies can act as early warning systems rather than virus spreading vehicles, if post-examination procedures for pathogens in the cabin and lavatories are in place.

2.5. Risks for the Clean Aviation initiative

When the Clean Sky 1 programme started in 2009, the coverage of its activities included nearly all commercial aviation segments and aircraft types (i.e. large passenger aeroplanes, regional aircraft, business jets, and helicopters). The post-2008 financial crisis shifted the centre of attention from the environmental challenges to include a broader focus on competitiveness issues. The result was, however, a less focused, more diverse and less impactful portfolio of technologies (both geographically and in terms of aircraft segments).

For Clean Aviation, the temptations of short-term solutions in response to the present crisis should be resisted as they risk locking the EU into a fossil fuel economy for the longer term. The limited research and innovation funds should not be subsumed into a wider COVID-19 recovery effort, for which there are better-suited instruments at EU and national level.

It should therefore be clear that the EU funding for the proposed Clean Aviation initiative does not aim to contribute to the aviation sector's cash flow balance nor will be able to resolve their post-COVID-19 financial difficulties, especially given that other EU and national programmes will be available for that purpose.

The added-value of the Clean Aviation initiative lies, rather, in providing a clear strategic direction for the aviation sector and its efforts to decarbonise.

3. ENVIRONMENTAL IMPACT OF AVIATION

3.1. Magnitude and trends

The civil aviation market has grown – as flying became much more accessible with the appearance of low-cost carriers and increased competition – combined with rising levels of disposable income, mobile student populations and few equivalent alternatives from other transport modes. While flying has become accessible to a wide audience, aviation is increasingly criticised for its perceived insufficient ambition to decarbonise.

The total impact of global aviation to greenhouse gasses (GHG) emissions in 2005 was estimated to represent 4.9% of total anthropogenic forcing, where 1.6% was attributed to CO₂ and 3.3% was attributed to non-CO₂ emissions. There are significant contributions, to better understanding the non-CO₂ emissions, which have both positive and negative radiative forcing effects and are not directly proportional to CO₂ emissions.

At European level, in 2016, aviation contributed to 3.6% of the total EU28 greenhouse gas emissions and to 13.4% of the total transport emissions. In absolute numbers, European aviation CO₂ emissions in 2016 were 171 million tonnes, while the total anthropogenic CO₂ emissions the same year were estimated to 36,000 million tonnes (or 0.4%). This shows that European aviation CO₂ emissions is not the only driving force of anthropogenic CO₂ emissions.

In 2017, Europe recorded strong and broad-based traffic growth taking flight totals to a record 10.6 million. In Europe, passenger traffic grew at an average rate of 4.4% per year between 2011 and 2018.

In 2018, over 1.2 billion passengers flew to and from over 500 airports in Europe. More than 3,500 intra-EU routes now provide access to both large cities as well as peripheral regions.

It is expected that flights in Europe will, post COVID-19, increase by 1.9% per year²⁹ to 2040, while at the global level flights may increase at 3.7% per annum.

Efficiency improvements are constantly being incorporated into newer generation aircraft, reducing fuel consumption and in turn reducing CO₂ and ufPM emissions, while improvements are also incorporated to reduce NO_x and noise but these are insufficient to counter the growing air traffic.

3.2. Scientific

Aviation has significant impacts on the environment: it contributes to climate change through the emission of carbon dioxide (CO₂) and nitrogen oxides (NO_x), but also through the emission of contrails, sulphur dioxide (SO₂), carbon monoxide (CO), hydrocarbons, ultra-fine particulate matter (ufPM) and soot. All are a product of kerosene (fossil fuel) combustion.

The impact of aviation on the environment and climate is driven by long-term effects (several years to hundreds of years) from CO₂ emissions and shorter-term ones (several hours, days, weeks or years), also from non-CO₂ emissions.

²⁹ https://www.eurocontrol.int/sites/default/files/2019-07/challenges-of-growth-2018-annex1_0.pdf

The CO₂ effects are well understood and emissions are proportional to the fuel used in aviation. The non-CO₂ (mainly water, nitrogen oxides, sulphur oxides, soot, contrails and contrail cirrus) effects emissions relating to aviation are still poorly understood and their effect on climate change largely unknown.

Additional key environmental issues are the generation of noise and particulate matter, specifically in the vicinity of airports where it has impacts on the population living close to the airport area as well as under the main flight paths for take offs and landings. More than 4,2 million people are exposed to harmful noise levels leading to cardiovascular diseases and stress, and more than 1 million people have their sleep disturbed.

The total impact of global aviation on greenhouse gas emissions in 2005 (the most recent complete and reliable available measurements) was estimated to represent 4.9% of the total, where 1.6% was attributed to CO₂ and 3.3% was attributed to non-CO₂ emissions.

There are no quick-fix solutions, but there are aviation research and innovations paths leading towards climate neutrality by 2050. Evolutionary and disruptive technological research, together with accelerated deployment of sustainable aviation fuels (biofuels and e-fuels) and operational optimisations (mostly related to air traffic management) are the key directions for aviation research to be supported under Horizon Europe.

3.3. Mitigation Measures

Airlines' operating business models are still driven by the cost per seat. Environmental issues have not been the central focus or have been considered as a side effect/ objective: for instance, the reduction in CO₂ emissions over the years has been driven by the incentive to reduce fuel costs (circa 25-35% of total operating costs) rather than reducing the environmental footprint. The full environmental costs of aviation are born by society rather than airlines and manufacturers, leading to sub-optimal investment in, and deployment of, new environmentally-friendly technologies.

The ICAO environmental report³⁰ (2019), based on extensive analysis and data, suggests that even under the most optimistic scenario, the projected long-term fuel efficiency of 1.37% per annum falls short of ICAO's aspirational goal of 2% per annum.

ICAO, in the 39th Assembly, recognised that despite the environmental benefits from aircraft technologies, operational improvements and sustainable alternative fuels, sufficient CO₂ emissions reductions to address the growth of international air traffic, will not be achieved in time (CNG2020). ICAO CORSIA - a global market-based measure was therefore designed to offset international aviation CO₂ emissions in order to stabilize the levels of such emissions. Provided that growth in passenger numbers and reductions in fuel consumptions continue at current rates, the overall effect is that emissions from the air transport industry will still continue to rise.

Figure Below: CO₂ Emissions from International Aviation - 2005 to 2050, (ICAO, 2019)

³⁰<https://www.icao.int/environmental-protection/pages/envrep2019.aspx>

The response of the aviation sector needs to go far beyond the incremental efficiency improvements that are constantly being incorporated into newer aircraft generations, reducing fuel consumption and in turn reducing emissions but at a much smaller rate (+/- 1.5% annually) than traffic growth, thus leading to a growing environmental impact from aviation.

In doing that, it would continue to fulfil its economic and societal role as the safest mode of transport³¹ & ³² and by far the most convenient one for medium and long-range distances.

4. POSITIONING OF THE EUROPEAN INDUSTRY IN AVIATION

Europe has become the global leader in the supply of large civil aircraft, as one half of the Airbus-Boeing duopoly. Two main European OEMs, Rolls Royce (UK/ D) and Safran (F), hold almost 40% of the world market for engines, and Safran and GE (USA) run a very successful joint venture (CFM) that dominates the global market for large civil aircraft engines. Europe is by far the international leader in the supply of civilian helicopters. Europe also plays a significant role in the market for maintenance, repair and overhaul of aircraft.

³¹ The number of accidents in the EU-28 in 2013 for three transport modes were: 16 aviation accidents, 1 982 railway accidents and 144 inland water transportation accidents (data for Bulgaria, the Czech Republic, Croatia, Hungary, Austria, Poland, Romania and Slovakia). The total number of fatalities amounts to eight from aeroplane accidents (fatalities from accidents on national territory regardless of the nationality of the aircraft operator); 1 130 from railway accidents, and 16 932 from road accidents (data for 20 out of the 28 EU Member States).

³² https://ec.europa.eu/eurostat/statistics-explained/index.php/Archive:Transport_accident_statistics

Four of the top ten aeronautical manufacturing companies by revenue are European; the others are US-based. The European industry also plays a key role in civil helicopters (Airbus Helicopters and Leonardo), engine manufacturing (Rolls-Royce-ITP, Safran, GE-AVIO, and MTU), and manufacturing, repairs and overhaul (MRO).

Through its direct, indirect and induced economic impact, aviation represents 3.3% of all employment and spurs 4.1% of the EU GDP in 2016³³.

Source: aviationbenefits.org/around-the-world/europe

The industry provides a positive contribution to the EU trade balance (EUR 96 billion in EU exports). In total, aviation supports 12.2 million European jobs and EUR 730 billion in European economic activity.

Compared to its key competitor, the USA, the European aeronautics industry has fewer companies of sufficient size and capability for large risk sharing projects, and crucially does not benefit to the same extent as US companies (such as Boeing, Lockheed Martin, and GE) from government-funded military and space research spill-over effects. R&D investments in the USA (from industry and government) are generally higher than in Europe³⁴. Lastly, the European industry is more exposed to currency exchange risks with sales and revenues expressed in USD (the preferred currency of the global aviation market) and costs made in Europe calculated in EUR³⁵.

Other aircraft manufacturers – such as UAC in Russia and COMAC in China – may in the future weaken the EU and US positions with very price competitive products, backed up by their large and expanding home markets³⁶. For example, in 2018 it was reported that the COMAC C919 aircraft, an A320neo and Boeing 737 competitor, has over 1,000 domestic

³³ <https://aviationbenefits.org/around-the-world/europe>

³⁵ <https://bizfluent.com/facts-6818189-exchange-rate-affects-business.html>

³⁶ https://www.rand.org/content/dam/rand/pubs/research_reports/RR200/RR245/RAND_RR245.pdf

orders³⁷ and is due to enter service in 2021. The aircraft's reported list price is USD 50 million, i.e. about half the cost of the equivalent Airbus and Boeing aircraft³⁸. Russia and China are also collaborating on a new wide-body aircraft, the CR929, to be ready for 2027. Additionally, aeronautics companies are setting up engineering offices in India to access cheaper labour and be active in promising markets. MRO companies are moving to the Middle East, pulled by the growing airlines in that region. Potential risks also arise from offshoring, including possible forced technology or intellectual property transfers. Airbus has final assembly lines in China and the USA and Rolls-Royce in Singapore³⁹.

Table 2: International competitiveness of the global aeronautics industry

1	2 Large Civil aircraft	3 Regional aircraft	4 Business /general aviation	5 Helicopter	6 Engines	7 MRO
8 Market Situation	9 Airbus/ Boeing Duopoly	10 All dominant players linked with Airbus/Boeing	11 Dominance of North American players	12 Dominant European and US players	13 Rolls Royce and Safran (CFM) are significant players	14 Many independent and dependent players

22 European Aeronautics Industry	23 Airbus has grown to compete for the market 50:50 with Boeing	24 Airbus purchased the C-Series from Bombardier. Airbus own a stake in ATR	25 Dassault and some smaller players	26 Civil market leader and technology leader	27 Rolls-Royce and Safran (through CFM) are major world players	28 Strong European position

Source: Competitiveness of the EU Aerospace Industry, Ecorys, 2009, updated by Steer to reflect market developments since (Technopolis, Steer, 2020).

The European aviation industry appears to be in a comfortable position. However, the EU aviation value chain is exposed to increasing international competition (from traditional competitors such as the USA, and from emerging countries like China and Russia) in a complex and global political environment.

In the US, the civil aeronautical industry benefits strongly from defence related research and development activities. The US Department of Defense^{40, 41} and China⁴² are investing huge

³⁷ <https://www.bizjournals.com/seattle/news/2018/03/21/chinas-rival-to-boeing-737-nowhas-nearly-1-000.html>

³⁸ It must be underlined though that the entry into market of this aircraft has been delayed several times

sums on research and innovation for all the underlying technologies relevant to aircraft engines. The US Department of Defense R&D budget in Y2020 amounts to a total of USD 92.3 billion⁴³.

In China, the government has identified the development of a national civil aeronautics industry as a key priority and sponsored⁴⁴ domestic aircraft purchases by Chinese airlines. Over the last decade the patents filled by China have multiplied tenfold. A recent analysis, performed by the UK's Aerospace Technology Institute, on global aerospace patents shows that China's patent quota system, employed since 1999, encouraged vast volumes of patent applications that seem largely superficial as few are converted to publications. Western aerospace companies are increasing their patent⁴⁵ activity in China, recognising the significance of the aviation market there but also the competitive threat posed by a rapidly maturing homegrown industry.

Aircraft engines is also one of the very few advanced technologies that Asian industries have not yet succeeded in developing – therefore relying on European and American engines. Made in China 2025⁴⁶ pays particular attention to that. Because of the synergies between civil and defence, the level-playing field is difficult to achieve.

5. AERONAUTICAL SCIENTIFIC AND TECHNOLOGICAL RESEARCH IN EUROPE

5.1. Scientific and technological achievements

Aeronautical scientific and technological research in Europe, with a transformational impact to air transport and humanity, started more than 100 years ago⁴⁷. Over a century, European aviation research led to scientific and technological advancements in new innovative aerostructures, engines and equipment. Today these innovations are found not only in aircrafts from European integrators (i.e. Airbus, Leonardo, Dassault, Saab). During the last three years, Boeing alone purchased European systems and equipment valued over EUR 25 billion from European suppliers providing employment to 190,000 Europeans⁴⁸.

The impact of **2,073 collaborative European aviation research projects** from FP2 to H2020 and the **demonstration and integration activities in two Clean Sky programmes** (under FP7 and H2020) has been particularly significant. Representative examples that have pronounced impact on clean aviation technologies include:

➔ **Lightweight composite aerostructures** R&I has peaked in FP7, where European research funding (330 ME total cost) enabled the development of new materials, new manufacturing technologies and new integration methodologies. Research efforts in FP6-ALCAS⁴⁹, FP7-MAAXIMUS⁵⁰, FP7-SARISTU⁵¹ and FP7-LOCOMACHS⁵² matured

⁴³<https://www.aia-aerospace.org/report/2019-facts-figures/>

⁴⁴<https://ustr.gov/sites/default/files/Section%20301%20FINAL.PDF> Page 33 onwards

⁴⁵ In aerospace, where long term technology maturity is often the case, patent filing numbers in isolation may not be conclusive and may not give a useful insight into technology strategies.

⁴⁶https://www.merics.org/sites/default/files/2017-09/MPOC_No.2_MadeinChina2025.pdf

⁴⁷ The Rijks-Studiendienst voor de Luchtvaart, the predecessor of today's Royal National Aerospace Laboratory (NLR) in the Netherlands, was established in 1919 in the north part of Amsterdam.

⁴⁸ Communication from Boeing to Commissioner Gabriel – dated 02 December 2019.

⁴⁹<https://cordis.europa.eu/project/id/516092>

⁵⁰<https://cordis.europa.eu/project/id/213371>

composite and adaptive wing technologies. These technologies were developed further by the private industries and finally integrated in the Bombardier C Series, in Belfast⁵³ (now the Airbus A220) and in the Airbus A350 (fuselage and wing).

Research in H2020 further developed innovative concepts and will be demonstrated in the Adapted Wing Integrated Demonstrator Flying test bed⁵⁴ under Clean Sky 2 in 2022. These lightweight composite wings, fuselage and nacelles account for **53% of the empty weight for the A350⁵⁵** and contributed to **25% greater fuel efficiency⁵⁶** than the competition. Such performance gains are attributed to focused R&I activities over three decades⁵⁷ and contribute to environmental gains and European supply chain leadership.

➔ **Ultra-efficient engines** contribute more than anything else in the reduction of the environmental footprint of aviation. They also embed classified (confidential) and patented innovations. In addition, they often share technologies (e.g. internal aerodynamics, high temperature materials and thermal barrier coatings) between civil, defence and even space applications.

The European engine manufacturers (i.e. Safran, Rolls-Royce, MTU and GE-AVIO) together with their American counterparts (GE and P&W) have established joint ventures and deliver propulsion units for all market segments.

Aircraft engines is also one of the very few advanced technologies that Asian industries have not yet succeeded in developing – therefore relying on European and American engines. Made in China 2025⁵⁸ pays particular attention to that. Because of the synergies between civil and defence, the level-playing field is difficult to achieve. The US Department of Defense⁵⁹ &⁶⁰ and China⁶¹ are investing huge sums on research and innovation for all the underlying technologies relevant to aircraft engines. The US Department of Defense R&D budget in Y2020 amounts to a total of \$92.3 billion⁶².

Research efforts in FP7-ENOVAL⁶³, FP7-LEMCOTEC⁶⁴, FP7-E-BREAK⁶⁵, FP7-NEWAC and an array of smaller low TRL R&I collaborative projects matured further low and high

⁵⁷ While European R&I on composite aerostructures started in the early 80s, the A350 programme started in 2007 with entry into service in 2013.

⁵⁸ https://www.merics.org/sites/default/files/2017-09/MPOC_No.2_MadeinChina2025.pdf

⁵⁹ <https://www.sbir.gov/content/high-temperature-materials-and-sensors-propulsion-systems>

⁶⁰ <https://www.nap.edu/read/10056/chapter/6>

⁶¹ <https://www.sciencedirect.com/science/article/pii/S100093611730273X>

⁶² <https://www.aia-aerospace.org/report/2019-facts-figures/>

⁶³ <https://cordis.europa.eu/project/id/604999>

⁶⁴ <https://cordis.europa.eu/project/id/283216>

pressure compressor and turbine parts as well as their combustion cycles towards ultra-high by-pass ratio propulsion systems.

These technologies were developed further by the engine manufacturers and integrated in engines that propel single-aisle and long-haul aircrafts (from Airbus and Boeing). In addition to the collaborative research within FP6, FP7 and H2020, Clean Sky 2 is contributing to the validation and demonstration of Very High Bypass Ratio Large turbofan (TRL 6 in 2023), Ultrahigh Propulsive Efficiency (TRL 5+ by mid-2022) and Advanced Geared Engine Configuration (TRL 5 by 2023).

Examples demonstrating the contribution of the EU-funded research to clean aircraft engines have been documented in the open access deliverables (e.g. FP7-NEWAC⁶⁶, and E-BREAK⁶⁷, Clean Sky⁶⁸) among other scientific publications. The success of the A320neo (New Engine Option) and possibly of B737max (after recertification) is/will be attributed mainly to new engines from GE-SAFRAN and P&W-MTU.

Finally, the **impact of aircraft engines R&I to the environmental footprint of aviation** can be easily quantified. In 2019, civil aviation consumed 380 billion litres of jet fuel. Aircraft engines contribute on the average around 1% of jet fuel efficiency per annum (i.e. **3.8 billion litres of aviation fuel saved per annum**, because of new engine technologies), which is **12 million tonnes of CO₂ less** in the atmosphere.

By increasing the research and development in those technologies and accelerating the development of even cleaner gas turbines, combined with other breakthrough technologies (e.g. hybrid-electric), the European Commission aims to have **250-300 million tonnes less CO₂ over the next 10 years, from aircraft engines alone**. There are no other technologies in the world today (apart from renewable energy) that can achieve such impressive CO₂ reductions. The renewal of the aircraft fleet can also contribute to even more accelerated impact. It is estimated⁶⁹ that yearly emissions equivalent to CO₂ released by 3 million cars could be avoided if half of the global aircraft fleet was equipped with new efficient engines.

5.2. patents and scientific publications

In terms of aviation R&I performance and in particular on **patents and scientific publications**, Europe shows strong leadership, especially in peer-reviewed publications and references with high impact factor. Out of the 50 journals on aerospace engineering⁷⁰ worldwide, 26 are based in Europe, including a clear lead in the total cites over the last three years. The EU-based journal, Progress in Aerospace Sciences, has one of the highest impact factors (9.27), while the EU-based journal Aerospace Science and Technology has one of the highest citation indexes over the last three years (4,113).

⁶⁵ <https://cordis.europa.eu/project/id/314366/reporting>

⁶⁶ https://trimis.ec.europa.eu/sites/default/files/project/documents/20121029_130736_70767_Publishable_Final_Activity_Report.pdf

⁶⁷ <https://cordis.europa.eu/docs/results/314/314366/final1-e-break-project-summary-handbook.pdf>

⁶⁸ <https://www.cleansky.eu/the-uhbr-engine-flight-testing-programme-gathers-momentum>

⁶⁹ <https://www.eco-business.com/news/how-the-aviation-industry-is-lowering-its-carbon-footprint/>

⁷⁰ <https://www.scimagojr.com/journalrank.php?category=2202&area=2200&type=all>

In terms of patents, leading European aeronautics companies hold an extensive portfolio (Airbus⁷¹: 37,000, Safran⁷²: 38,000, Thales⁷³: 15,000). In the EU-funded aviation R&I a considerable number of patents is requested – often after the end of the project (e.g in FP7-SARISTU and FP7-AFLONEXT). In the first Clean Sky programme⁷⁴ a significant number of requests for patent (196) were registered and most of them (166) have been granted.

However, over the last decade the patents filled by China have multiplied tenfold. A recent analysis, performed by the UK’s Aerospace Technology Institute, on global aerospace patents⁷⁵ shows that China’s patent quota system, employed since 1999, encouraged vast volumes of patent applications that seem largely superficial as few are converted to publications.

Western aerospace companies are increasing their patent activity in China, recognising the significance of the aviation market there but also the competitive threat posed by a rapidly maturing indigenous industry. In aerospace, where long term technology maturity is often the case, patent filing numbers in isolation may not be conclusive and may not give a useful insight into technology strategies.

Finally, additional anecdotal evidence **on the relative scientific and technological performance of Europe in aviation** and related clean technologies can be obtained by assessments performed outside of Europe. The government of Canada⁷⁶ assessed that the EU is a key partner in science, technology and innovation for Canada and a major source of new technologies, in particular in the areas of health and aeronautics.

5.3. 2019 Industrial R&D Scoreboard

As regards the R&D investment in the field, EU companies are well positioned compared to the rest of the world according to the 2019 Industrial R&D Scoreboard⁷⁷. The 39 top companies of the Aerospace & Defence sector in terms of R&D investment invested close to EUR 20bn in R&D in 2018 worldwide, where EU companies represent 46% of the investments, slightly more than the USA. This followed a slight decrease over the last 10 years, whereas global R&D growth in 2018-19 was driven by the ICT and the health sector. The table below lists the key indicators for the top 20 companies investing in R&D categorised in this sector, highlighting the ones located in the EU.

Figure Top 2500 companies investing in R&D worldwide – Focus on Aerospace and Defence 20 top companies

World rank	Company	Country	Region	R&D 2018/19 (€million)	R&D year growth (%)	one-year growth	Net sales one-year growth (%)	R&D intensity (%)	Employees

Note: Figures displayed refer only to the 386 out of the 551 EU companies with R&D data available for the all period 2009-2018. These companies represent 86.6% of R&D whole sample in 2018. Source: *The 2019 EU Industrial R&D Investment Scoreboard. European Commission, JRC/DG RTD.*

In terms of scientific performance, the EU28 shows a good performance compared to the rest of the world based on scientific publications in the field of aerospace engineering. Based on Scopus data, EU28 publications represents 23 % of all publications in the field with close to 40,000 publications between 2014 and 2019, involving close to 60,000 authors. Worldwide the most prolific country is China with more than 50,000 publications, followed by the United States (40,000). Publications from authors with affiliations in Germany, the UK, Italy, and France are the best positioned in the EU. The Field Weighted citation Index shows that EU28 publications in the field are cited 23% more than the world average whereas the ones from China show a lower performance than the average. Looking at trends in the field, during the period 2014-2019, the main topics of prominence worldwide (“hot topic”) in terms of publications appeared related to physics, chemistry, chemical engineering, materials sciences and engineering but also energy and environmental sciences.

Figure - Research output in aerospace engineering worldwide – Top 25% topics of Prominence 2014-2019

Source: Scival, based on Scopus data

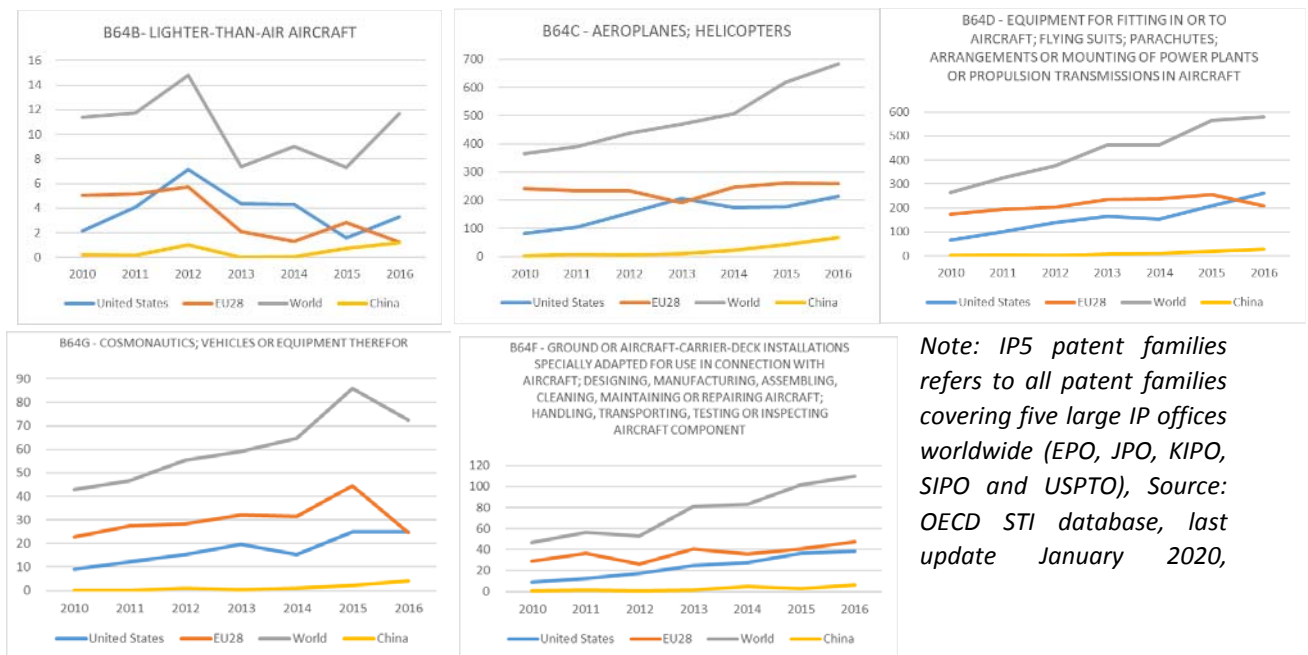

In terms of technological performance, between 2010 and 2016 the EU overall maintains a stable higher performance compared to the USA (details in the Figure below per specific technologies). When looking in the EU industrial R&D Scoreboard at the share of green patenting with respect to the total technological inventions of the biggest R&D investors worldwide, the highest share of green over total patents is revealed by companies operating in transport-related industries, including aerospace & defence (23.2%), totalising almost 3,900 green over more than 17,000 patents in the period 2012-2015, and automobiles and other transports (20.1%). These companies concentrate their green inventions in green transportation technologies. From the top 25 green inventors among the top R&D investors, green patents represent 28% of the patents of the company United Technologies (USA), 20% of the patents filed by Airbus (EU), and 34% of the patents filed by Rolls Royce (UK-DE).

6. ROLE OF EASA IN RESEARCH AND INNOVATION

For new aircraft products, operations and services certification is the gateway from research and development to market uptake, as a compulsory guarantee of safety and environmental compliance. The cost, time and uncertainty related to certification are important factors in preparing new products and services.

The European Union Aviation Safety Agency (EASA) is in charge of certification in Europe, including for technologies developed in EU programmes. However, EASA participation in early R&D activities has been hindered due to the lack of dedicated resources. The solution has been addressed in the context of the revision of the EASA Regulation currently adopted by the Commission that aims – amongst other things – to strengthen the Agency's work in the field of certification.

It is important to shorten time-to-market and to decrease costs of the development and operation of new air transport products and services, notably for market-creating innovations. This would help increase the European share in the fast-growing global market despite increasing global competition.

The cycle from preparation to completion of certification tests for large aircraft can take more than five years. A six-month delay in delivery to an airline can lead to penalties for the manufacturer of up to 2% of the price of each aircraft, or cancellation of orders to the benefit of competitors. Development costs exceed EUR 10 billion for a new large aircraft. If a design issue is detected at a late stage of the certification process, the development costs can increase by 10%. The cycle design-build-test-redesign drives up costs and leads to delays.

Following the R&D stage, all new aviation products and services need to be certified for safety and environmental compliance before market uptake. Therefore, EASA participation is needed in early R&D stages to avoid issues and delays later at the certification level.

Early preparation of certification is particularly important in EU programmes supporting aviation research & innovation, deployment and investment e.g. Horizon 2020 (including Clean Sky 2 and SESAR 2020 JTIs), Connecting Europe Facility (including Single European Sky Deployment) and Structural Funds (at least 20 EU regions include aeronautics among the targeted sectors).

Research underpins the new certification processes and the new regulations, including those adopted internationally by the United Nations International Civil Aviation Organisation (ICAO), where EASA is called upon to play a more active role. The supporting technical evidence put forward firstly by one country (typically USA) is influential in the final decision. The act setting up the US Federal Aviation Administration includes provisions not only for safety regulation but also for the promotion of aeronautics and air-transportation in such a manner as to best foster their development adapted to US commercial needs.

The improvement of certification with EASA participation in early R&D activities can also contribute to three other policy objectives of the Commission, namely: strengthening Europe's role as a global actor, notably at ICAO, where global regulations are discussed among aviation authorities on the basis of evidence collected e.g. from R&D programmes. Timely involvement of EASA in R&D activities could accelerate the pace of setting European regulations and standards, which could then become a reference at global level.

The main issue relates to uncertainties in the timely and cost-efficient development and certification of innovative air transport products, operations and services if EASA is not involved at early stages of the R&I process. Certification issues increase costs and delays, put orders at risk, endanger market penetration, and reduce returns on investments for European companies. In a global market worth an estimated EUR 5000 billion over the next 20 years, each drop of 1% in market share equates to a potential loss of EUR 2.5 billion per year to the European industry.

7. CLEAN SKY BACKGROUND

7.1. The first Clean Sky programme:

The Clean Sky Joint Undertaking (JU)⁷⁸ was created in 2008 as a public-private partnership (PPP) between the European Union (EU) and the aeronautics industry. The first research programme, Clean Sky, had a value of EUR 1.6 billion and was launched under the Seventh Framework Programme, FP7. The EU and industry each contributed 50% of this budget. Clean Sky aimed to demonstrate and validate the technology breakthroughs that are necessary to make major steps towards the environmental goals sets by Advisory Council for Aeronautics Research in Europe (ACARE), the European Technology Platform for aeronautics and air transport, and to be reached in 2020:

- 50% reduction of CO₂ emissions through drastic reduction of fuel consumption.
- 80% reduction of NO_x (nitrogen oxide) emissions.
- 50% reduction of external noise.

⁷⁸ <http://www.cleansky.eu/>

- A green product life cycle: design, manufacturing, maintenance and disposal/recycling.

Clean Sky consisted of six Integrated Technology Demonstrators (ITDs):

1. Smart Fixed-Wing Aircraft.
2. Green Regional Aircraft.
3. Green Rotorcraft.
4. Sustainable and Green Engines.
5. Systems for Green Operations.
6. Eco-Design.

Clean Sky (FP7) had different levels of membership:

- Leaders – the 12 Leaders received 50% of the funding. Two key industry players were appointed to lead each of the six ITDs for the duration of the programme. The Leaders were listed in the Annex to the JU's founding Regulation⁷⁹;
- Associates – the 71 Associates received 25% of the funding. They were private or public organisations, selected through open calls, as permanent members of the Clean Sky JU. They committed to perform, and complete, certain essential work packages in one or more of the ITDs for the duration of the programme.
- Partners – the over 500 Partners received 25% of the funding. They were private or public organisations, selected via Calls for Proposals, that participated for certain specific tasks over a limited period in the programme.

⁷⁹ Council Regulation (EC) No 71/2008 of 20 December 2007 setting up the Clean Sky Joint Undertaking

7.2. The Clean Sky 2 programme

For the second programme under Horizon 2020, Clean Sky 2, a new Clean Sky 2 Joint Undertaking was established in 2014. It was responsible for carrying out the activities of both Clean Sky programmes until the first programme ended in 2017. The new Clean Sky 2 programme has a budget of approximately EUR 4 billion. The EU contributes EUR 1.755 billion and private members EUR 2.2 billion. Clean Sky 2 retains the three tiers of membership:

- **Leaders** – now 16 rather than 12. They receive 40% of funds.
- **Core Partners** – Associates have been re-named as Core Partners, of which 256 have been selected. They receive 30% of the funding.
- **Partners** – Selected via Calls for Partners and are not members of the JU, but contribute to a specific, time-limited, task. Over 730 organisations have been selected from the 10 calls. They receive 30% of the funding.

Clean Sky 2 aims to integrate, demonstrate and validate the most promising technologies capable of:

- increasing aircraft fuel efficiency and reducing CO₂ emissions by 20 to 30% compared to state-of-the-art aircraft entering into service as from 2014.
- reducing aircraft NOx emissions by 20 to 30% compared to 'state-of-the-art' aircraft entering into service as from 2014.
- reducing aircraft noise emissions levels by up to 5dB – using the recognised effective perceived noise levels decibel (EPNdB) standard – per operation compared to 'state-of-the-art' aircraft entering into service as from 2014.

These objectives follow-on from those of the Clean Sky programme but are however more ambitious as they use a more up-to-date reference year, i.e. 2014 rather than 2000. In particular, the fuel efficiency and CO₂ emissions reduction of up to 30% will overtake the average 10-15% reduction for a new generation of aircraft. This will accelerate twice the rate of improvement otherwise achievable and could result in 'skipping a generation' of nominal development.

An additional aim of the Clean Sky 2 programme is industrial competitiveness; it aims at global leadership for European aeronautics, with a competitive supply chain, which includes academia, research bodies and SMEs.

7.3. Interim Evaluation of the CS2 Joint Undertaking

The Interim Evaluation Report⁸⁰ of CS2 JU, published in 2017, noted that the scope of activity identified is still considered relevant. It observed that the scope of CS2 was expanded compared to that of CS1 and also highlighted that recent political developments (such as the 2015 Paris Agreement) underscore even further the need to do everything possible to accelerate the development and introduction of environmentally friendly products and services. The Interim Evaluation and stakeholder discussions held for this study highlighted a number of issues, include the following observations:

Governance: Technology Evaluator: its limited scope (i.e. only technology and only inside Clean Sky 2) is not ideal. It is also dependent on the goodwill of the CS2 SPDs to provide it with input and information. The fact that the Technology Evaluator is within

⁸⁰ Interim Evaluation of the Clean Sky 2 Joint Undertaking (2014-2016) operating under Horizon 2020, Experts Group Report <https://ec.europa.eu/research/evaluations/pdf/cs2.pdf>

Clean Sky 2 may also raise questions regarding its objectivity in assessing CS2's technological achievements;

Scientific Committee: This could have greater focus on technological challenges than on Clean Sky 2 internal management;

States' Representative Group (SRG): there is a need for stronger interaction between Governing Boards and its advisory bodies (States' Representatives Group and Scientific Committee). Efficient collaboration between these bodies is of critical importance to the purposeful functioning and successful outcome of the JUs. A concern expressed related to the low impact of the advisory bodies on the Governing Boards' strategic decisions. For example, the SRG did not seem to have fulfilled its full potential in ensuring a close relationship with Member States in order to influence the Clean Sky programme or to develop synergies with their national research strategies. The Commission needs to stimulate the States' Representative Group to contribute to maximising the leverage effect of research programme synchronisation. The statutory SRG is not actively contributing to Clean Sky coordination with aeronautics research funded by the Member States.

Openness: A more integrative programmatic approach to managing work would be more effective and that there should be greater transparency regarding accomplishments and funding. In particular, the Interim Evaluation highlighted:

- Easier and more proactive disclosure of the parties and their funding;
- The economic impact of the programme should be better promoted, even if this may take years to be realised;
- As a scientific programme, some questioned whether CS2 should not have been able to contribute to more research publications.

Research: Call topics should be less prescriptive and funds should be allocated to create opportunities in areas that CS2 does currently not operate;

- The evaluation suggested to optimise 'complementarity and synergy' with the demonstrator projects while nurturing the bottom-up inspired 'innovation pipeline'.

Technical: Relationships between research activity and the demonstrator objectives in the broad framework should be clearer. Alternative views of research are needed to create visibility in the intended application of each technology development, whilst alternative views of accomplishments are needed to provide an overview of technology maturity – increased insight.

Management and communications: Current administrative processes are not always suitable and add much complexity and rigidity to the management process. The following points were identified:

- Options aim at reducing administrative workload (including grant administration) should be considered.
- Concerns were raised regarding the suitability of the Delegation Agreement.
- Greater use should be made of subcontracting in high TRL projects;
- CS2 currently operates with a top-down structure. A mechanism could be in place to foster more bottom-up working.

7.4. Clean Sky 2 Interim Evaluation Recommendations

The report provided ten points regarding the operation and its environment as elements to take into consideration for the Clean Sky 2 programme, applicable for the design and implementation of large-scale aeronautics research projects, such as Clean Sky 2 at the same time it could apply for the proposed European Partnership on Clean Aviation. The solutions will depend on the combined talents of all the Clean Sky stakeholders to take the right steps for the short and long-term continuity of this programme.

The Delegation Agreement

It is clearly not in the best interests of the CS2 JU to implement the Delegation Agreement that was made with the Commission under its Establishing Regulation just for the sake of it. The Commission should motivate the JU on each point, with reference to their specific needs and the available support for these transitions. The management of the grant agreements for members and research product archive system are two areas that could be considered inappropriate to migrate but the CS2 JU is the best judge of what will best meet their needs and responsibilities.

The framework, rules and suitable derogations should be considered well in advance of the drafting of a Basic Act for future programmes.

Administrative Simplification

Other options for meeting financial controlling requirements in grant administration, at reduced administrative workload, for future large-scale projects should be explored. The governance structure and the dedicated Programme Office of the JU are unique JTI feature that should permit a higher level of trust based operation than would apply to grant management by an Executive Agency.

The Horizon 2020 Aeronautics Innovation Pipeline

The CS2JU's best efforts should be made to convert appropriate parts of the Clean Sky 2 research agenda into call topics that are much less prescriptive than their current practice. Thus, funds could be allocated – where feasible without negative impact on demonstrators objectives – to create opportunities for research in areas that Clean Sky 2 does not currently address, the gaps.

Stimulate Subcontracting

It seems obvious now that the call topics in high TRL development work are small, of short duration, and highly-specified work packages that are valued at less than a few million Euros in value. They are probably not worth the effort of the call for proposal and grant management process. There are adequate mechanisms in place for transparency of subcontracting and increased use of that approach to 'outsourcing' seems preferable. A substantial increase of efficiency should be realised.

A Holistic Approach for Aeronautics Research

The maturity of collaborative, cross border research in the aeronautics research community and the close supply chain integration of the participating entities would suggest that a more integrative programmatic approach to managing this research area would be very effective. An additional responsibility of the CSJU for a collaborative

research work programme would optimise complementarities and synergies' with the demonstrator projects while nurturing the bottom-up inspired innovation pipeline.

Increased Transparency

Finding the recipients of public funding is for Clean Sky can be found but not very easily. The accomplishments of Clean Sky 1 and the objectives of Clean Sky 2 merit substantial respect. The best place for disclosure of the parties and their funding is right next to the accomplishments of each element of the research programme as these are achievements, or goals, to be proud of. The dedicated followers of the Clean Sky electronic newsletter would be pleased to be the first to know about new grant awards.

Increase Insight

The relationships between research activity and the demonstrators' objectives in the broad Clean Sky framework are not always clear and this will not be solved by putting more detail in the breakdown of work based descriptions or the progress reports. Alternative views of research are needed to create visibility in the intended application of each technology development, to ensure that the baseline is indeed state-of-the-art and to prevent research from being duplicated. Alternative views of the *accomplishments* are needed for an overview of the technology maturity that was realised in the programme, the application (or not) of the research outcomes in the realisation of the demonstrators and the contribution of the research to a marketable product. These measurements of the ability of the partners to both choose targets and accomplish them are much stronger performance indicators than milestones and deliverables currently being monitored.

Synergies with National Research

The statutory SRG is not actively contributing to Clean Sky coordination with aeronautics research funded by the Member States. Although synergies are being created by the wake effect of Clean Sky's visibility, and the Clean Sky insights that the SRG members acquire, the Commission needs to further stimulate the SRG to contribute to maximising the leverage effect of research programme synchronisation.

Promote Economic Impact

In the end, the Clean Sky programmes will be judged on the basis of their real world impact and – although that will sometimes take decades to materialise in a new, green air transport fleet – there are still methods by which the predicted benefits of the Clean Sky programmes can be made more substantial. Improved monitoring of industrial uptake, both intended and actual, combined with the elaboration of the scope of the Technology Evaluator to include socio economic impact all promote the need for the programme.

Energise and Enable Academic Participation

Academic participation in demonstrator work tends to focus on established aeronautic research partners that have the facilities and experience to support 'high TRL' development work. Herein lies an opportunity to expand the aeronautics research support base for Clean Sky. The main avenues to exploit could be:

- Enable students to contribute in an industrial environment, particularly in SMEs, which would not otherwise have that luxury, as a subject for PhD research. The "Initial Training Network" approach of the Marie Skłodowska-Curie Actions (MSCA) is a good basis from which to develop a unique 'Clean Sky' approach.

- Engage with universities to explore the unexplained outcomes of Clear Sky research that the ITD/ IAPDs do not prioritise in their own scope of work.
- Import new knowledge, solutions and innovation potential by finding ideas in other sciences and sectors.
- Reward excellent academic performance in the area of transition from fundamental to applied research thru grants, awards, prizes that energize and enable the academic community.

7.5. Clean Sky 2 Joint Undertaking Organisational chart

The Establishment Plan foresees 44 staff in total, out of which 42 staff members [36 Temporary Agents (TA) + 6 Contractual Agents (CA)] and 2 Seconded National Experts (SNE).

Source: CS 2 JU

The governance of the CS2 JU comprises:

- A Governing Board, including representatives of the founding members, Core Partners and the Commission (with 50% of the voting rights); Observers of the Governing Board include the Chairs of the States' Representative Group, and Scientific Committee.
- An Executive Director, supported by three Heads of Unit (Strategy and Horizontal Affairs, Programmes, and Administration and Finance), responsible for day-to-day management.
- A series of Steering Committees responsible for the technical decisions taken within each Integrated Technology Demonstrators (ITD)/ Innovative Aircraft Demonstration Platforms (IADP) and in the Technology Evaluator as set out below.
- A Scientific Committee providing advice to the Governing Board.
- A States' Representative Group (SRG) acting as an advisory body to the Governing Board.
- Various Working Groups.

7.6. Clean Sky 2 Stakeholder analysis

Up to 40% of CS2's available funding is allocated to its 16 Leaders (and their affiliates), and up to 30% to Core Partners, leaving only 30% of the funding to be distributed through calls for proposals and calls for tenders for which industry, SMEs, research organisations and academia are all eligible.

A key objective for the CS2 JU, as defined in Council Regulation 558/2014, is the active promotion of the participation and close involvement of all relevant stakeholders from the full aviation value chain, including from outside the traditional aviation industry in aeronautics-related R&I. The Impact Assessment study analysed this, by NACE industry sector and type of entity. Note that this mapping of the partnership network is based on an identification of the participants in the partnership projects, derived from CORDA.

The results lead to a number of conclusions concerning participation in CS2:

The majority of funding went to private companies, specifically equipment manufacturers. On SMEs participation, information from stakeholders differs with ASD stating that 420 SMEs participated (with a SMEs Call for Partners funding share of 34% (of the 30% of funding reserved for Calls) with the SME average size of topics at EUR 600,000), and European Aerospace Cluster Partnership (EACP) noting that the current small allocation of funding to SMEs stifles innovation and that more funding should be allocated to foster innovation. Note that the 70% of budget that was pre-allocated to the Leaders and Core Partners included very few SMEs.

The JU has involved participation from organisations throughout the value chain, including aircraft manufactures, engine manufactures and avionic manufacturers, as well as research and educational institutions: ASD⁸¹ indicates 373 research centres, 350 universities were involved in addition to 334 bigger industrial organisations.

The weightings of the participating organisations imply a relatively even spread in participation among the organisations, however it should be noted that if the constituent parts of Airbus were to be grouped into one entity it would clearly dominate.

Educational and scientific and research institutions are well represented although, participation is concentrated on a relatively limited number of organisations with NLR, Onera, CIRA, DLR, and *Fraunhofer Gesellschaft* (FhG) being the dominant research organisation, and the University of Nottingham and *Technische Universiteit Delft* being the dominant higher education institutions.

8. THE H2020 EUROPEAN AVIATION RESEARCH LANDSCAPE

Under H2020, two Joint Undertakings are active in the aviation research area. Both these Joint Undertakings have their own specific objectives.

8.1. SESAR

SESAR is dedicated to optimising air traffic management in Europe – in particular in terms of capacity, cost, and safety. This means air traffic management infrastructure, ground and air operations, and to a limited extent aircraft system functionalities. It is strongly linked to the Single European Sky policy.

Most of the industrial partners involved in SESAR have also a prominent role in Clean Sky 2, but SESAR has other important partners, such as Eurocontrol and representatives of airports who are not in Clean Sky 2.

For the future, air traffic management (ATM) has great room for efficiency improvements by progressing with the implementation of the Single European Sky

⁸¹ ASD, 2019

(SES) and further R&I on the Digital European Sky. The fragmented, national organisation of ATM, and the ineffective regulatory framework hinder the technical solutions to be deployed. The legislative process for improving SES has been blocked at Council level for over six years. The proposed European Partnership on Integrated ATM would continue the work of the current SESAR Joint Undertaking. An optimised ATM could lead to a 5 to 10% reduction of emissions if deployed.

8.2. Clean Sky 2

Clean Sky 2 is about optimising the aircraft performance, in particular with regards to environment, [fuel] efficiency and emissions. Clean Sky 2 can be considered to be the predecessor of the Clean Aviation initiative.

The Clean Sky 2 Joint Undertaking has the following objectives:

- to contribute to the finalisation of research activities initiated under Regulation (EC) No 71/2008 and to the implementation of Regulation (EU) No 1291/2013, and in particular the Smart, Green and Integrated Transport.
- to contribute to improving the environmental impact of aeronautical technologies, including those relating to small aviation, as well as to developing a strong and globally competitive aeronautical industry and supply chain in Europe. This can be realised through speeding up the development of cleaner air transport technologies for earliest possible deployment, and in particular the integration, demonstration and validation of technologies capable of:
 - increasing aircraft fuel efficiency, thus reducing CO₂ emissions by 20 to 30% compared to 'state-of-the-art' aircraft entering into service as from 2014;
 - reducing aircraft NO_x and noise emissions by 20 to 30 % compared to 'state-of-the-art' aircraft entering into service as from 2014.

8.3. Cooperation

A memorandum of understanding between the two current H2020 partnerships was signed in December 2015 to exploit areas of mutual interest. The cooperation is leading to:

- coordinating call topics and check if parallel activity is underway, and if needed adapt or even drop the topic in preparation of the Annual Work Plans
- Information exchanges from projects where the analysis of topics shows a benefit to coordinate
- joint communications and coordination of messages
- Extra technical reviews to ensure the complementarity and avoid duplication.
- The two Scientific Committees are 'connected' and exchanges are encouraged
- Experts and reviewers are shared

For the future, some initial discussions between the two JUs including a number of private stakeholders have taken place to analyse possible areas of shared/joint interest between the proposed Integrated Air Traffic Management and Clean Aviation partnerships under Horizon Europe.

A number of areas of possible joint demonstration were identified. The cooperation between the two future programmes could be intensified to ensure that progress in aircraft technology is matched by and is in step with the evolution of ATM and infrastructure capabilities. This is particularly relevant given the evolution in the objectives of the ATM partnership towards ‘Digital Skies’ including areas of automation and autonomy in aircraft and/or ground systems.

The implementation of these joint demonstration activities can be clarified and more areas of cooperation can be defined, once the two programmes are up and running under Horizon Europe. A new memorandum of co-operation between the two new partnerships would then be established.

8.4. Collaborative research

Collaborative research in aviation and aeronautics has been funded by the EU since the fourth framework programme that started in 1994. Since the establishment of Clean Sky, collaborative research projects on aviation have continued to be funded under FP7 and then H2020⁸². This is mainly because the projects’ focus did not fall under the scope of the Joint Undertakings. For example, projects dealing with issues not covered by Clean Sky – for example, safety, international co-operation⁸³, aviation within multi-modal transport, or providing a snapshot of EU aviation research infrastructure – or because they concentrated on more fundamental research at a lower TRL. Under H2020, apart from a few Coordination and Support Actions (CSA), the Commission has delegated the projects’ management to its Innovation and Networks Executive Agency (INEA)⁸⁴.

8.5. Note: National research programmes

Next to the European aviation research and innovation programmes there are national aviation R&I programmes with significant budgets such as those of Germany (LuFo), France (CORAC) and the UK (ATI), with a budget of between EUR 2-3 billion for a period of five years.

However, an external study shows that these programmes were not sufficiently coordinated, neither at national level nor at European level. In some cases, national interest in local employment and technology, led to non-complementary policies, with a possible duplication of activities. The consultation showed that the situation has improved, however stakeholders recognised that there is room for further improvement.

9. STAKEHOLDER REACTION TO THE CLEAN AVIATION INITIATIVE

9.1. Joint Declaration of European Aviation Research Stakeholders

The earliest official recognition of the value of the Clean Aviation initiative by the private sector came under form of a “Joint Declaration of European Aviation Research

⁸² https://ec.europa.eu/inea/sites/inea/files/aviation_brochure_2019-web.pdf

⁸³ Thirteen non-EU countries have been involved in international co-operation during H2020, including .Japan, China, Canada, United States, Russia and Brazil.
https://ec.europa.eu/inea/sites/inea/files/aviation_brochure_2019-web.pdf, p36

⁸⁴ <https://ec.europa.eu/inea/>

Stakeholders”⁸⁵ handed over to Jean-Eric Paquet, Director-General for Research and Innovation, European Commission at the 2019 Le Bourget Airshow.

It was signed by twenty-three Aeronautics Industry leaders, Research Organisations and University Associations from across Europe to express their strong commitment to a future European partnership leading to a deep decarbonisation of aviation by 2050.

9.2. Shared vision

This Joint Declaration was further developed into a “shared vision”, published in January 2020, that recognised that the sector the sector has a duty to act and the power to lead, given support of the European Union, in bringing aviation in line with the European Green Deal.

This shared vision was signed by a broad spectrum of industrial parties, universities, research and technology organisations, EASA, and several associations such as Pegasus, EREA and EASN.

This shared vision already underlined several of the key success factors that have also been addressed in this Impact Assessment.

- The importance of establishing an eco-system for aviation and actively seek and develop synergies with other European Partnerships, EU research programmes, national research and innovation programmes.
- The focus on integration, demonstration and validation of technology.
- The need to involve the wider aviation community to raise awareness, and instil the necessary confidence for long-term investments needed for product development, and to build confidence among airlines and operators.
- The need to align the technical research effort with policy and legislative elements and new infrastructure provisions required for early market acceptance efforts.
- Strong pro-active European Union support on global regulation, standards for and certification of future products, supported through a strong and strategic alignment with EASA.

It also contained a first brief description of the technical dimension of the Clean Aviation initiative including an integrated roadmap comprises four key thrusts aiming at the selection of best approaches and solutions for maturation:

- Full Electric Aircraft and Rotorcraft – maturing technologies towards demonstration of novel configurations, on-board energy concepts and flight control in the small/ commuter segment.
- Hybrid Electric Aircraft – driving research into ultra-efficient aircraft structures, configurations, novel power sources and management, and their integration; aiming predominantly at regional and short-range applications.

⁸⁵ <https://www.cleansky.eu/news/aviation-industry-declares-commitment-to-future-clean-aviation-partnership>

- Ultra-efficient Aircraft and Gas Turbines – to address the short, medium and long-range needs with highly integrated, ultra-efficient gas turbines.
- Sustainable Aviation Fuels-enabled Aircraft – driving the capability of aircraft and engines to fully exploit the potential of both drop-in and non-drop-in alternative low and zero carbon fuels.

9.3. Strategic Research and Innovation Agenda

The Shared Vision was intensely debated between private stakeholders, and with the Commission.

The private sector formed a working group, called CS3PG, responsible to deliver in a timely, open and transparent manner an aligned position from the European aviation stakeholders of an ambitious programme, in support of the Commission's strategic planning and preparatory work towards a legislative proposal on a potential European Institutionalised Partnership on Clean Aviation under Article 187 Treaty on the Functioning of the European Union.

CS3PG members include industrial companies, both large and small; academia; research organisations from across the EU; seven⁸⁶ of the 34 stakeholders preparing the SRIA are not members of the current partnership, including three associations from academia; and Member States.

This significant and sustained effort led to a Strategic Research and Innovation agenda that was released on 1 July 2020.

9.4. Public consultation

The CS3PG organised a public consultation on the SRIA from 15 May -11 June 2020. The 530 respondents from 31 different countries provided more than 1500 comments contributed to the CS3PG analyses of the SRIA leading in some cases to new lines of approach.

Remarkable the high number of SMEs (16%) and private citizens (36%) that provided their feedback and showed interest in the potential European Partnership for Clean Aviation. This indicates that the survey was broadly communicated and reached also the general public and shows that the general public gives importance to the subject.

⁸⁶ Association of European Research Establishments in Aeronautics (EREA); European Aeronautics Science Network (EASN); European Union Aviation Safety Agency (EASA); KU Leuven; Lufthansa Technik; Pegasus (Partnership of the European aerospace universities); Pipistrel (an SME)

Are or were you directly involved in a partnership under Horizon 2020 or its predecessor under the Framework Programme 7?

Are or were you directly involved in a partnership under Horizon 2020 or its predecessor under the Framework Programme 7, or in the preparations of any proposed partnerships under Horizon Europe?

10. POTENTIAL LINKS AND SYNERGIES WITH OTHER PARTNERSHIPS AND EU PROGRAMMES AND INITIATIVES

The Clean Aviation Partnership will work towards establishing strategic synergies with other European Partnerships and Horizon Europe cross-cutting initiatives:

Sustainable Aviation Fuels

Sustainable aviation fuels (SAF) will make a crucial contribution to mitigating the current and expected future environmental impacts of aviation. Thus, it is important that EU initiatives related to sustainable [bio]-fuels include a dedicated area to address the development, production and deployment of bio- or synthetic aviation fuels as well as the logistics and required adaptations of the airport infrastructure.

Clean Hydrogen

Fuel cells represent a unique opportunity to reduce CO₂ emissions thanks to their high system efficiency of about 50% and their higher power density compared to batteries, as well as not releasing NO_x or particulates. They have also a very low noise footprint. It is necessary, to prepare the next generation of innovations, products and services, in close alignment with the Clean Hydrogen and Fuel Cell Initiative, to ensure a European technology breakthrough of this value chain in air transportation.

European battery research

Batteries are a valuable solution for full or partial electrification through hybridisation, mixing electric engines with on-board electricity production. As fundamental battery research cannot be addressed in the Clean Aviation programme, European battery research should include a dedicated area to accelerate towards the very high requirements for aviation to contribute their potential towards climate neutral aviation.

Integrated Air Traffic Management

As autonomous operations are expected to be key drivers for the next generation of aircraft, the research programme activities dealing with the flight management of the vehicle need to be well aligned with research aspects and activities regarding air traffic management as tackled in the SESAR 2020 Programme and the Integrated Air Traffic Management Partnership proposed under Horizon Europe.

Artificial Intelligence

Artificial intelligence will be required to contribute to achieve the ambitious goals of Clean Aviation, starting from design, manufacturing, testing and certification, operation and maintenance of aircraft as well as efficient and secure passenger management.

Electronics / Semi-conductors

The proposed Clean Aviation Partnership agenda relies on several complementary research activities proposed under the Electronic Components and Systems for European Leadership Joint Undertaking (ECSEL JU) regarding electronic components and systems and semiconductor manufacturing.

Advanced Materials and Structures

New materials, their future production processes and assembly techniques are key complementary contributors to improved performance and reduced environmental footprint. An effective systemic approach between Clean Aviation and several Horizon Europe initiatives, such as Made by Europe, Climate Neutral and Circular Industry and the European Institute of Innovation and Technology (EIT) Manufacturing and EIT Raw Material is key to maximise the results.

Security

As in many other sectors, increased automation and autonomy in systems of aircraft are expected to significantly increase the competitiveness. Security and increasingly cybersecurity are prerequisites for making use of the fast-increasing potential of new automated functions in aviation. Large-scale use of digital data/ data transfer e.g. wideband data link between aircraft and ground will require an increased focus of cybersecurity. Here the inherent safety and security of the on-board systems is at stake. Therefore, the fundamental issues of cyber resilience will be tackled in the Global Challenges Digital Europe and dedicated Horizon Europe initiatives, but it needs to be

ensured that their respective work programmes will assign appropriate topics and that their resources will cover the challenging aviation specific requirements.

11. CLEAN AVIATION RESPONSES TO CLEAN SKY 2 PERCEIVED SHORTCOMINGS

As explained in the impact assessment, the H2020 CS2 Joint Undertaking has a number of weaknesses that should be addressed when establishing a new Article 187 Partnership.

The most prominent weaknesses are:

- The scope of the Clean Sky 2 Joint Undertaking research and innovation programme has demonstrated being **too broad**; lacking the focus needed for achieving strategic disruptive results and for making a substantial contribution to the objectives described in the Clean Sky 2 Basic Regulation. The research effort revolves around incremental improvements to existing technologies and not on new technologies with potential step change capabilities.
- Further shortcomings are its **governance** with a Governing Board overloaded with administrative issues, a scientific body and a state representatives group with purely advisory functions, and a technology evaluator embedded in the Joint Undertaking and dependent on the goodwill of the private partners for information.
- It lacks **openness** with 70% of the Clean Sky 2 budget pre-allocated to the leaders (40%) and core partners (30%), leaving only 30% of the budget for open calls. This strongly limits flexibility and the possibility for new parties (including SMEs) to join the partnership.
- The funding imbalance between traditional calls (20%) and Joint Undertaking funding allocation (80%).

The analysis shows that the institutionalised European Partnership option would be the best-suited, provided it takes into account all lessons from the experiences with Clean Sky and Clean Sky 2 – both positive and negative. In particular:

- The dedicated programme office providing in-house programme management capacities would allow **closer monitoring and swift adaptation** of the research effort,
- Demonstrator selection will be based upon **open calls** (no pre-allocated budget), including criteria to assess real-world impact and providing a business case for market uptake. This should also lead to new Clean Aviation **partners outside the core players** (academia, SMEs, countries without a strong aviation industry) to bring technologies that are not common knowledge for aviation.
- In addition, much more attention will be paid to embedding supporting functions such as **environmental and safety certification**, (close collaboration with the European Union Aviation Safety Agency is envisaged) also on an international level, into the research effort. Managing these aspects in parallel to the research effort, instead of the current sequential approach, would ensure that all conditions are met for swift market introduction at the end of the programme.
- A strong governance is envisaged under the JU basic act to monitor progress with the help of an **independent assessment instrument** and steer the research effort on basis of achieved results, and to **maximise synergies with other initiatives** such as the initiatives on batteries or hydrogen, and with national research programmes.

- The strong involvement of the EC services will ensure alignment with EC priorities and policies.

A list of the perceived shortcomings of Clean Sky 2, as outcome of the mid term evaluation, is included in the impact assessment. This list is copied below with a brief description of how these shortcomings could be prevented in future by the Clean Aviation partnership.

<p>Clean Sky 2</p>	<p>Project participation rates are distributed in favour of a relatively limited number of organisations. A large share of the funding is reserved to Leaders and Core Partners. There is a risk that SMEs or EU-13 Member States participants may find it difficult to join it, as project participation in the CS 2 JU is concentrated among a relatively limited number of players reflecting the composition of leaders and core partners</p> <p>collaborative aviation R&I, over the last decade, compared to the large budget for demonstration, has adversely affected the availability and spectrum of lower technology readiness levels</p>	<p>Aspects of the design and implementation of the CS 2 JU have limited effectiveness: certain aspects of its governance arrangements such as the role of the States Representative Group</p>	<p>negative impact on the "time to market", which benefits from the assessment of potential safety risks and environmental standards related to certification of new products and technologies. Safety topics and certification issues regarding Similarly, elements of CS2 JU procedural infrastructure are constraining the R&I effort. There is arguably a need for greater flexibility and for reduction in the administrative burden. There are also some communication improvements that could be made</p>	<p>It is not always easy to establish what the precise outcomes of CS1 and CS2 have been</p>
---------------------------	--	---	--	--

<p>Clean Sky 2</p> <p>There is a lack of multi-level policy coordination, whilst horizontal coordination between research, technology and innovation policies is good in the European aviation sector</p> <p>programmes, one of the weaknesses of the European research landscape is that there is no systematic alignment, and no single roadmap, of the various aviation related research programmes leading to overlaps,</p> <p>Overall, the CS2 programme has not contributed to the alignment of national and EU aviation research programmes – apart from creating some synergies with EU regional funds as outlined in the CS2 2018 Annual Activity Report. In addition, efforts to develop more electric systems as well as composite aero structures were often duplicated by partners, while opportunities for synergies were not exploited</p>	<p>Clean Aviation proposal</p>
	<p>All project and demonstrator selection through open calls.</p>
	<p>Exploit synergies with other partnerships, and research initiatives that could contribute to Clean Aviation.</p> <p>collaborative research and the Clean Aviation initiative. Strong focus of the Clean Aviation partnership on high TRL demonstrator projects while collaborative research will concentrate on low TRL research, mainly unrelated to the Updated Governance structure giving the governing board the direct responsibility for maintaining and evolving the strategic research and innovation agenda, for monitoring projects and demonstrators.</p>
	<p>All other groups such as Impact assessment group, states representatives group, stakeholders group to report directly to the Governing Board.</p> <p>EASA structurally involved from the outset of the initiative for monitoring and impact assessment, advice on safety related issues and assessing the potential environmental performance of the new technologies.</p> <p>Simplification of the governance and increased focus on the management of the research programme and projects instead of administration that could be dealt with by the Executive Director of the Programme Office.</p> <p>Increased transparency and evaluation of progress against the Green Deal ambitions and deadlines. Demonstrator projects could be expected to introduce realistic roadmaps for bringing their technologies to market.</p>

<p align="center">Clean Aviation proposal</p>
<p>Increased involvement of the Commission to ensure the link between European policy initiatives and research.</p>
<p>Development of a European strategic research and Innovation roadmap. Involvement of ACARE as stakeholders group in identifying opportunities for synergies and cooperation.</p>
<p>States Representatives Group with dedicated mandate to ensure the alignment of the European research effort with the national research programmes.</p>
<p>Dedicated related communication effort describing European research needs which could be met by national research activities.</p>

PART 1 - COMMON FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1. BACKGROUND AND CONTEXT TO EUROPEAN PARTNERSHIPS IN HORIZON EUROPE AND FOCUS OF THE IMPACT ASSESSMENT– WHAT IS DECIDED

1.1 Focus and objectives of the impact assessment

This impact assessment accompanies the Commission proposal for Institutionalised European Partnerships to be funded under Horizon Europe, the 2021-2027 Framework Programme for EU Research and Innovation (R&I).¹ It sets out to **help decide in a coordinated manner the right form of implementation for specific candidate initiatives** based on a common approach and methodology to individual assessments². It also provides an **horizontal perspective on the portfolio of candidate European Partnerships** to identify further efficiency and coherence gains for more impact.

European Partnerships are initiatives where the Union, together with private and/or public partners (such as industry, public bodies or foundations) commit to support jointly the development and implementation of an integrated programme of R&I activities. The rationale for establishing such initiatives is to achieve the objectives of Horizon Europe more effectively than what can be attained by other activities of the programme.³

Based on the Horizon Europe Regulation, European Partnerships may be set up using **three different forms**: “Co-funded”, “Co-programmed” and “Institutionalised”. The setting-up of **Institutionalised Partnerships** involves new EU legislation and the establishment of dedicated implementing structures based on Article 185 or 187 of the Treaty on the Functioning of the EU (TFEU). This requires an impact assessment to be performed.

The Horizon Europe Regulation defines **eight priority areas**, scoping the domains in which Institutionalised Partnerships could be proposed⁴. Across these priority areas, **13 initiatives** have been identified as **suitable candidate initiatives** for Institutionalised Partnerships because of their objectives and scope. This impact assessment aims to identify whether 12 of these initiatives⁵ need to be implemented through this form of implementation and would not deliver equally well with traditional calls of Horizon Europe or other lighter forms of European Partnerships under Horizon Europe. This means assessing whether each of these initiatives meets the necessity test set in the **selection criteria** for European Partnerships in the Horizon Europe Regulation, Annex III.

This assessment is done **without any budgetary consideration**, as the overall budget of the Multiannual Financial Framework of the EU – and hence of Horizon Europe – for the next financing period is not known at this stage.⁶

¹ Horizon Europe Regulation (common understanding), <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

² Based on the European Commission Better Regulation framework (SWD (2017) 350) and supported by an external study coordinated by Technopolis Group (to be published in 2020).

³ For further details on these points, see below Section 1.2.2.

⁴ Set out in the Annex Va of the Horizon Europe Regulation (common understanding). <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

⁵ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47).

⁶ EU budget commitments to the European Partnership candidates can only be discussed and decided following the political agreement on the overall Multiannual Financial Framework and Horizon Europe budgetary envelopes. The level of EU contribution for individual partnerships should be determined once there are agreed objectives, and clear commitments

1.2 The political and legal context

1.2.1 Shift in EU priorities and Horizon Europe framework

European priorities have evolved in the last decades, and reflect the social, economic, and environmental challenges for the EU in the face of global developments. In her Political Guidelines for the new European Commission 2019 – 2024⁷, the new Commission President put forward six overarching priorities, which reach well beyond 2024 in scope⁸. Together with the Sustainable Development Goals (SDGs), these priorities will shape future EU policy responses to the challenges Europe faces, and thus also give direction to EU research and innovation.

As part of the Multi-annual Financial Framework (MFF) 2021-27 the new EU Framework Programme for Research and Innovation **Horizon Europe will play a pivotal role for Europe to lead the social, economic, and environmental transitions needed to achieve these European policy priorities**. It will be more impact driven with a strong focus on delivering European added value, but also be more effective and efficient in its implementation.⁹ Horizon Europe finds its rationale in the daunting challenges that the EU is facing, which call for “*a radical new approach to developing and deploying new technologies and innovative solutions for citizens and the planet on a scale and at a speed never achieved before, and to adapting our policy and economic framework to turn global threats into new opportunities for our society and economy, citizens and businesses.*” While Horizon Europe continues the efforts of strengthening the scientific and technological bases of the Union and foster competitiveness, a more strategic and impact-based approach to EU R&I investment is taken. Consequently, the **objectives of Horizon Europe** highlight the need to *deliver on the Union strategic priorities and contribute to the realisation of EU objectives and policies, contribute to tackling global challenges, including the Sustainable Development Goals by following the principles of the Agenda 2030 and the Paris Agreement.*¹⁰

In this context, **at least 35 % of the expenditure from actions under the Horizon Europe Programme will have to contribute to climate action**. Furthermore, a **Strategic Plan** is co-designed with stakeholders to identify **key strategic orientations for R&I support** for 2021-2024 in line with the EU priorities. In the Orientations towards the first Strategic Plan for Horizon Europe, the need to strategically prioritise and “*direct a substantial part of the funds towards the areas where we believe they will matter the most*” is emphasised. The Orientations specify, that actions under Pillar II of Horizon Europe “Global Challenges and European Industrial Competitiveness” will target only selected themes of especially high impact that significantly contribute to delivering on the political priorities of the Union. Most of the candidate European Partnerships fall under this Pillar.

from partners. Importantly, there is a ceiling to the partnership budgets in Pillar II of Horizon Europe (the legal proposal specifies that *the majority of the budget in pillar II shall be allocated to actions outside of European Partnerships*).

¹⁰ Article 3, Common understanding regarding the proposal for Horizon Europe Framework Programme.

1.2.2 Key evolutions in the approach to partnerships in Horizon Europe

Since their start in 1984 the successive set of Framework Programmes uses a variety of instruments and approaches to support R&I activities, address global challenges and industrial competitiveness. Collaborative, competition-based and excellence-driven R&I projects funded through Work Programmes are the most traditional and long-standing approach for implementation. Since 2002, available tools also include **partnerships**, whereby the Union together with private and/or public partners commit to jointly support the development and implementation of a R&I programme. These were introduced as part of creating the European Research Area (ERA) to align national strategies and overcome fragmentation of research effort towards an increased scientific, managerial and financial integration of European research and innovation. Interoperable and integrated national research systems would allow for better flows of knowledge, technology and people. Since then, the core activities of the partnerships consist of building critical mass mainly through collaborative projects, jointly developing visions, and setting strategic agendas.

As analysed in the **interim evaluation of Horizon 2020**¹¹, a considerable repertoire of partnership initiatives have been introduced over time, with 8 forms of implementation¹² and close to 120 partnership initiatives running under Horizon 2020 - without clear exit strategies and concerns about their degree of coherence, openness and transparency. Even if it is recognised that these initiatives allow setting long-term agendas, structuring R&I cooperation between otherwise dispersed actors, and leveraging additional investments, the evaluation points to the complexity generated by the proliferation of instruments and initiatives, and their insufficient contribution to policies at EU and national level.

Box 1 Key lessons from the interim evaluation of Horizon 2020 and R&I partnerships

- The **Horizon 2020 Interim Evaluation** concludes that the overall partnership landscape has become overly complex and fragmented. It identifies the need for rationalisation, improve their openness and transparency, and link them with future EU R&I missions and strategic priorities.
- The **Article 185 evaluation** finds that these public-public partnerships have scientific quality, global visibility and networking/structuring effects, but should in the future focus more on the achievement of policy impacts. From a systemic point of view, it found that the EU public-to-public cooperation (P2P) landscape has become crowded, with insufficient coherence.
- The **Article 187 evaluation** points out that Public-Private Partnership (PPP) activities need to be brought more in line with EU, national and regional policies, and calls for a revision of the Key Performance Indicators. As regards the **contractual PPPs (cPPPs)** their reviews identified challenges of coherence among cPPPs and the need to develop collaborations and synergies with other relevant initiatives and programmes at EU, national and regional level.

Over 80% of respondents to the Open Public Consultation (OPC) indicated that a significant contribution by future European Partnerships is 'fully needed' to achieve climate-related goals, to develop and effectively deploy technology, and for EU global competitiveness in specific sectors/domains. Views converged across all categories of respondents, including citizens, industry and academia.

¹¹ Interim evaluation of Horizon 2020, Commission Staff Working Document, SWD(2017)221 and 222 Interim evaluation of the Joint Undertakings operating under Horizon 2020 (Commission Staff Working Document, SWD(2017) 339); Evaluation of the Participation of the EU in research and development programmes undertaken by several Member States based on Article 185 of the TFEU, Commission Staff Working Document, SWD (2017)340

¹² E.g. initiatives based on Article 187 (Joint Technology Initiatives), Article 185 TFEU, Contractual Public-Private Partnerships (cPPPs), Knowledge & Innovation Communities of the European Institute of Innovation & Technology (EIT-KICs), ERA-NETs, European Joint Programmes, Joint Programming Initiatives.

The impact assessment of Horizon Europe identifies therefore the need to **rationalise the EU R&I funding landscape**, in particular with respect to partnerships, as well as to **re-orient partnerships towards more impact** and delivery on EU priorities. To address these concerns and to realise the higher ambition for European investments, Horizon Europe puts forward **a major simplification and reform for the Commission’s policy on R&I partnerships**¹³. Reflecting its pronounced systemic nature aimed at contributing to EU-wide ‘transformations’ towards the sustainability objectives, Horizon Europe indeed intends to make a more effective use of these partnerships with a **more strategic, coherent and impact-driven approach**. Key related changes that apply to all forms of European Partnerships encapsulated in Horizon Regulation are summarised in the Box below.

Box 2 Key features of the revised policy approach to R&I partnerships under Horizon Europe based on its impact assessment

- ✓ **Simpler architecture & toolbox** by streamlining 8 partnership instruments into 3 implementation forms (Co-Funded, Co-Programmed, Institutionalised), under the umbrella ‘European Partnerships’
- ✓ **More systematic and transparent approach** to selecting, implementing, monitoring, evaluating and phasing out all forms of partnerships (**criteria** for European Partnerships):
 - The selection of Partnerships is embedded in the strategic planning of Horizon Europe, thereby ensuring coherence with the EU priorities. The selection criteria require that partnerships are established with stronger ex-ante commitment and higher ambition.
 - The implementation criteria stipulate that initiatives adopt a systemic approach in achieving impacts, including broad engagement of stakeholders in agenda-setting and synergies with other relevant initiatives to promote the take-up of R&I results.
 - A harmonised monitoring & evaluation system will be implemented, and ensures that progress is analysed in the wider context of achieving Horizon Europe objectives and EU priorities.
 - All partnerships need to develop an exit strategy from Framework Programme funding. This new approach is underpinned by principles of openness, coherence and EU added value.
- ✓ **Reinforced impact orientation:**
 - Partnerships are established only if there is evidence they support achieving EU policy objectives more effectively than other Horizon Europe actions, by demonstrating a clear vision and targets (**directionality**) and corresponding long-term commitments from partners (**additionality**).
 - European Partnerships are expected to provide mechanisms – based on a concrete roadmap - to join up R&I efforts between a broad range of actors towards the development and uptake of innovative solutions in line with EU priorities, serving the economy and society, as well as scientific progress.
 - They are expected to develop close synergies with national and regional initiatives, acting as dynamic change agents, strengthening linkages within their respective ecosystems and along the value chains, as well as pooling resources and efforts towards the common EU objectives.

Under Horizon Europe, a ‘European Partnership’¹⁴ is defined as *“an initiative where the Union, prepared with early involvement of Member States and/or Associated Countries, together with private and/or public partners (such as industry, universities, research organisations, bodies with a public service mission at local, regional, national or international level or civil society organisations including foundations and NGOs), commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”*

The Regulation further specifies that European Partnerships shall adhere to the *“principles of Union added value, transparency, openness, impact within and for Europe, strong leverage effect on sufficient scale, long-term commitments of all the involved parties, flexibility in implementation, coherence, coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions.”*

¹³ Impact assessment of Horizon Europe, Commission Staff Working Document, SWD(2018)307.

¹⁴ Article 8 and Annex III of the Horizon Europe Regulation (common understanding)

1.3 Why should the EU act

1.3.1 Legal basis

Proposals for Institutionalised European Partnerships are based on:

- 1) Article 185 TFEU which allows the Union to make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; or
- 2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes.¹⁵

1.3.2 Subsidiarity

The EU should act only in areas where there is demonstrable advantage that the action at EU level is more effective than action taken at national, regional or local level. Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the EU can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas. The candidate initiatives focus on areas where there is a demonstrable value added in acting at the EU level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national activities in the same area. Overall European Partnerships find their **rationale in addressing a set of systemic failures**¹⁶:

- Their primary function is to create a platform for a strengthened **collaboration** and knowledge exchange between various actors in the European R&I system and an enhanced **coordination** of strategic research agendas and/or R&I funding programmes. They aim to address **transformational failures** to better align agendas and policies of public and private funders, pool available resources, create critical mass, avoid unnecessary duplication of efforts, and leverage sufficiently large investments where needed but hardly achievable by single countries.
- The concentration of efforts and pooling of knowledge on common priorities to solve multi-faceted societal and economic challenges is at the core of these initiatives. Specifically, enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems are among the key objectives of these instruments. In the light of Horizon Europe, the aim is to **drive system transitions and transformations towards EU priorities**.
- Especially in fast-growing technologies and sectors such as ICT, there is a need to **react to emerging opportunities** and address systemic failures such as shortage in skills or critical mass or cross-sectoral cooperation along the value chains that would hamper attainment of future European leadership and/or strategic autonomy.
- They also aim to address **market failures** predominantly to enhancing industry investments thanks to the sharing of risks.

¹⁵ Both Articles are under Title XIX of the TFEU - Research and Technological Development and Space.

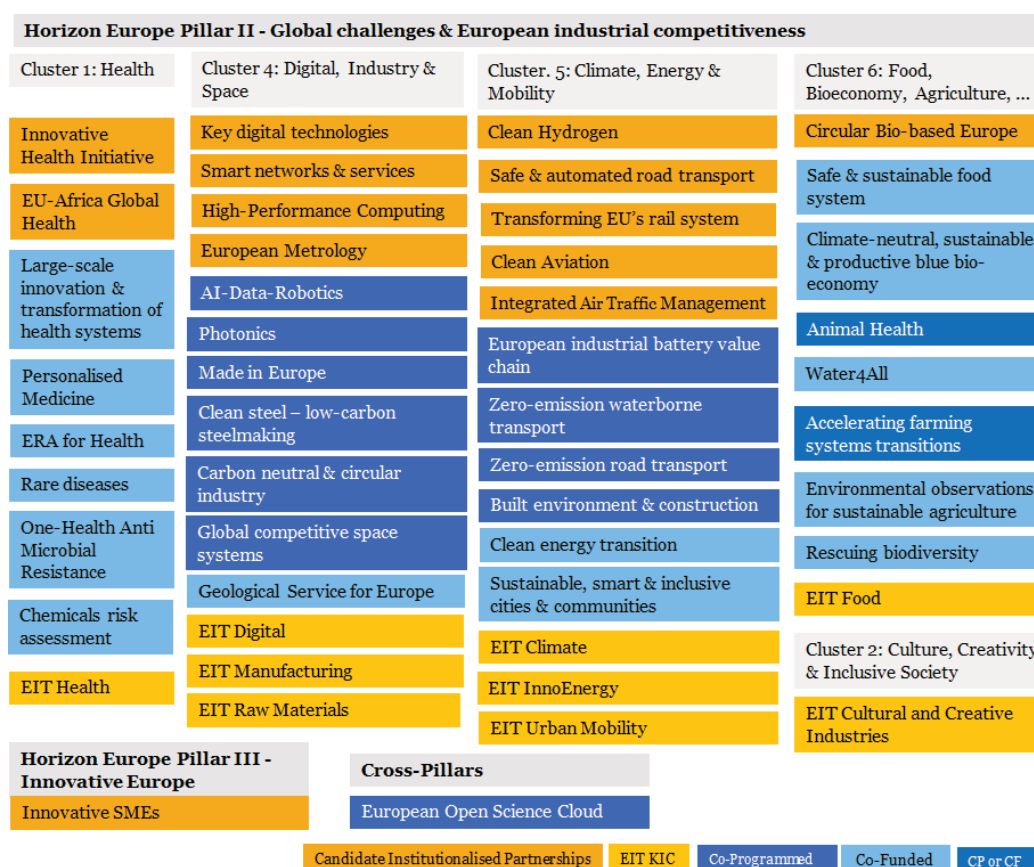

¹⁶ The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide qualitative and quantitative evidence on these points. Sections 1 and 2 of each impact assessment on candidate European Partnerships include more detail on the necessity to act at EU level in specific thematic areas.

2. THE CANDIDATE EUROPEAN PARTNERSHIPS – WHAT NEEDS TO BE DECIDED

2.1 Portfolio of candidates for Institutionalised European Partnerships

The new approach for more objective-driven and impactful European Partnerships is reflected in the way candidate Partnerships have been identified. It involved a co-design exercise aiming to better align these initiatives with societal needs and policy priorities, while broadening the range of actors involved. Taking into account the 8 areas for Institutionalised European Partnerships set out in the Horizon Europe Regulation¹⁷, a co-design exercise as part of the Strategic Planning process of Horizon Europe lead to the identification of **49 candidates for Co-funded, Co-programmed or Institutionalised European Partnerships**¹⁸. Out of these, **13 were identified as suitable candidate Institutionalised Partnerships because of their objectives and scope**¹⁹. Whilst the Co-Funded and Co-Programmed Partnerships are linked to the comitology procedure (including the adoption of the Strategic Plan and the Horizon Europe Work Programmes), Institutionalised Partnerships require the adoption of legislation and are subject to an impact assessment. The Figure below gives an overview of all candidate European Partnerships according to their primary relevance to Commission priorities for 2019-2024.

Figure 1 - Overview of the candidates for Co-Funded, Co-Programmed and Institutionalised European Partnerships according to Horizon Europe structure

Source: Technopolis group (2020)

¹⁷ Horizon Europe Regulation (common understanding), Annex Va.

¹⁸ Shadow configuration of Strategic Programme Committee for Horizon Europe. The list of candidate European Partnerships is described in “Orientations towards the Strategic Plan of Horizon Europe” - Annex 7

¹⁹ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47)

There are only three partnerships for which implementation as an Institutionalised Partnership under Article 185 is an option, i.e. European Metrology, the EU-Africa Global Health partnership, and Innovative SMEs. Ten partnerships are candidates for Institutionalised Partnerships under Article 187. Overall the initiatives can be categorised into ‘horizontal’ partnerships and ‘vertical’ partnerships.

The ‘horizontal’ partnerships have a central position in the overall portfolio, as they are expected to develop methodologies and technologies for application in the other priority areas, ultimately supporting European strategic autonomy in these areas as well as technological sovereignty. These ‘horizontal’ partnerships are typically proposed as Institutionalised or Co-programmed Partnerships, in addition to a number of EIT KICs, they cover mainly the digital field in addition to space, creative industries and manufacturing, but also the initiative related to Innovative SMEs. ‘Vertical’ partnerships are focused on the needs and development of specific application areas, and are primarily expected to support enhanced environmental sustainability thereby addressing Green Deal related objectives. They also deliver on policies for more people centred economy, through improved wellbeing of EU citizen and the economy, like health related candidate European Partnerships.

2.2 Assessing the necessity of a European Partnership and possible options for implementation

Horizon Europe Regulation Article 8 stipulates that Institutionalised European Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

For all candidate Institutionalised European Partnerships the options considered in this impact assessment are the same, i.e.:

- Option 0 – Baseline option – Traditional calls under the Framework Programme
- Option 1 – Co-programmed European Partnership
- Option 2 – Co-funded European Partnership
- Option 3 – Institutionalised Partnership
 - Sub-option 3a Institutionalised Partnerships based on Art 185 TFEU
 - Sub-option 3b Institutionalised Partnerships based on Art 187 TFEU

2.2.1 Option 0 - Baseline option – Traditional calls

Under this option, strategic programming for R&I in the priority area will be done through the mainstream channels of Horizon Europe. The related priorities will be implemented through **traditional calls** of Horizon Europe covering a range of actions, mainly R&I and/or innovation actions but also coordination and support actions, prizes or procurement. Most actions involve consortia of public and/or private actors in ad hoc combinations, while some actions are single actor (mono-beneficiary). There will be no dedicated implementation structure and no support other than what is foreseen in the related Horizon Europe Work Programme. This means that discontinuation costs/benefits of predecessor initiatives should be factored in for capturing the baseline situation when relevant.

Under this option, strategic planning mechanisms in the Framework Programme will allow for a high level of flexibility in the ability of traditional calls to respond to particular needs over time, building upon additional input in co-creation from stakeholders and programme committees involving Member States. The Union contribution to addressing the priority covers the full duration of the initiative, during the lifetime of Horizon Europe. Without a formal EU partnership mechanism, it is less likely that the stakeholders will develop a joint Strategic Research Agenda and commit to its implementation or agree on mutual commitments and contributions outside their participation in funded projects.

2.2.2 European Partnerships

Under this set of options, three different forms of implementation are assessed: Co-funded, Co-Programmed, Institutionalised European Partnerships. These have **commonalities that cannot serve as a distinguishing factor in the impact assessment process**. They are all based on agreed objectives and expected impacts and underpinned by Strategic Research and Innovation Agendas / roadmaps that are shared and committed to by all partners in the partnership. They all have to follow the same set of criteria along their lifecycle, as defined in the Horizon Europe Regulation (Annex III), including ex ante commitment from partners to mobilise and contribute resources and investments. The Union contribution is defined for the full duration of the initiative for all European Partnerships. The Horizon Europe legal act introduces few additional requirements for Institutionalised Partnerships, e.g. the need for long-term perspective, strong integration of R&I agendas, and financial contributions.

Figure 2 - Key differences in preparation and implementation of European Partnerships

Type	Legal form	Implementation
Co-Programmed	Contractual arrangement / MoU	Division of labour , whereby Union contribution is implemented through Framework programme and partners' contributions under their responsibility.
Co-Funded	Grant Agreement	Union provides co-funding for an integrated programme with distributed implementation by entities managing and/or funding national research and innovation programmes
Institutionalised based on Article 185/187 TFEU	Basic act (Council regulation, Decision by European Parliament and Council)	Integrated programme with centralised implementation

The main differences between the different forms of European Partnerships are in their preparation and in the way they function, as well as in the overall impact they can trigger. The Co-Programmed form is assessed as the simplest, and the Institutionalised the most complex to prepare and implement. The functionalities of the different form of Partnerships – compared to the baseline option – are presented in Figure 3. They relate to the types of actors Partnerships can involve and their degree of openness, the types of activities they can perform and their degree of flexibility, the degree of commitment of partners and the priority setting system, and their ability to work with their external environment (coherence), etc. These key distinguishing factors will be at the basis of the comparison of each option to determine their overall capacity to deliver what is needed at a minimised cost.

Figure 3 Overview of the functionalities provided by each form of European Partnerships, compared to the traditional calls of Horizon Europe (baseline)

Baseline: Horizon Europe calls	Option 1: Co-Programmed	Option 2: Co-Funded	Option 3a: Institutionalised Art 185	Option 3b: Institutionalised Art 187
Type and composition of actors (including openness and roles)				
<p><u>Partners:</u> N.A., no common set of actors that engage in planning and implementation</p> <p><u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules</p>	<p><u>Partners:</u> Suitable for all types: private and/or public partners, foundations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules</p>	<p><u>Partners:</u> core of national funding bodies or government-mental research organisations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> limited, according to national rules of partner countries</p>	<p><u>Partners:</u> National funding bodies or governmental research organisation</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations</p>	<p><u>Partners:</u> Suitable for all types: private and/or public partners, foundations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations</p>
Type and range of activities (including additionality and level of integration)				
<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions</p> <p><u>Additionality:</u> no additional activities and investments outside the funded projects</p> <p><u>Limitations:</u> No systemic approach beyond individual actions</p>	<p><u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake</p> <p><u>Additionality:</u> Activities/investments of partners, National funding</p> <p><u>Limitations:</u> Limited systemic approach beyond individual actions</p>	<p><u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake</p> <p><u>Additionality:</u> National funding</p> <p><u>Limitations:</u> Scale & scope depend on participating programmes, often smaller in scale</p>	<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach</p> <p><u>Additionality:</u> National funding</p>	<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds).</p> <p><u>Additionality:</u> Activities/investments of partners/ national funding</p>
Priority-setting process and directionality				
<p><u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years.</p> <p><u>Limitations:</u> Fully taking into account existing or to be developed SRIA/ roadmap</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Input to FP annual work programme drafted by partners, finalised by EC (comitology)</p> <p>Objectives & commitments set in contractual arrangement</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by EC</p> <p>Objectives & commitments set in Grant Agreement</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by EC</p> <p>Objectives & commitments set in legal act</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners & EC, covering usually 7 years, incl. allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by EC (veto-right in governance)</p> <p>Objectives & commitments set in legal act</p>
Coherence: internal (Horizon Europe) & external (other Union programmes, national programmes, industrial strategies)				
<p><u>Internal:</u> Coherence between different parts of the FP Annual Work programme can be ensured by EC</p> <p><u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Limited synergies with other Union programmes & industrial strategies. If MS participate, with national/ regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Synergies with national/ regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Synergies with national/ regional programmes & activities</p>	<p><u>Internal:</u> Coherence among partnerships & with parts of the FP Annual Work programme can be ensured by partners & EC</p> <p><u>External:</u> Synergies with other Union programmes and industrial strategies</p> <p>If MS participate, with national/ regional programmes & activities</p>

2.2.2.1 Option 1 - Co-programmed European Partnership

This form of European Partnership is **based upon a Memorandum of Understanding or a Contractual Arrangement** signed by the Commission and the private and/or public partners. Private partners are represented by industry associations, which also support the daily management of the partnership. This type of partnership would allow for a large degree of flexibility for the activities, partners and priorities to continuously evolve. The commitments of partners are political efforts described in the contractual arrangement and the contributions from partners are provided in kind more than financially. The priorities for the calls, proposed by the Partnership's members for integration in the Horizon Europe's Work Programmes, are subject to further input from Member States (comitology) and Commission services. The Union contribution is implemented within the executive agency managing Horizon Europe calls for research and innovation projects proposals. The full array of Horizon Europe instruments can be used, ranging from research and innovation (RIA) types of actions to coordination and support actions (CSA) and including grants, prizes, and procurement.

2.2.2.2 Option 2 – Co-funded European Partnership

The Co-funded European Partnership is **based on a Grant Agreement** between the Commission and a consortium of partners, resulting from a specific call in the Horizon Europe Work Programme. This form of implementation only allows to address public partners at its core. Typically these provide co-funding to a common programme of activities established and/or implemented by entities managing and/or funding national R&I programmes. The recipients of the EU co-funding implement the initiative under their responsibility, with national funding/resources pooled to implement the programme with co-funding from the Union. The expectation is that these entities would cover most if not all EU Member States. Calls and evaluations would be organised centrally, beneficiaries in selected projects would be funded at national level, following national funding rules.

2.2.2.3 Option 3 – Institutionalised European Partnership

This type of Partnership is the most complex and high-effort arrangement, and requires meeting additional requirements. Institutionalised European Partnership are **based on a Council Regulation (Article 187 TFEU or a Decision by the European Parliament and Council (Article 185 TFEU))** and are implemented by dedicated structures created for that purpose. These regulatory needs limit the flexibility for a change in the core objectives, partners, and/or commitments as these would require amending legislation. The basic rationale for this type of partnership is the need for a strong integration of R&I agendas in the private and/or public sectors in the EU in order to address a strategic challenge. It is therefore necessary to demonstrate that other forms of implementation would not achieve the objectives or would not generate the necessary expected impacts, and that a long-term perspective and high degree of integration is needed. For both Article 187 and 185 initiatives, contributions from partners can be in the form of financial and in-kind contributions. Eligibility for participation and funding follows by default the rules of Horizon Europe, unless a derogation is introduced in the basic act.

Option 3a - Institutionalised Partnerships based on Article 185 TFEU

Article 185 of the TFEU allows the Union to participate in programmes jointly undertaken by Member States and limits therefore the scope to **public partners** which are Member States and Associated Third Countries. This type of Institutionalised Partnership aims

therefore at reaching the greatest possible impact through the integration of national and EU funding, aligning national strategies in order to optimise the use of public resources and overcome fragmentation of the public research effort. It brings together R&I governance bodies of most if not all EU Member States (legal requirement: at least 40% of Member States) as well as Associated Third Countries that designate a legal entity (Dedicated Implementation Structure) of their choice for the implementation. By default, participation of non-associated Third Countries is not foreseen. Such participation is possible only if it is foreseen in the basic act and subject to conclusion of an international agreement.

Option 3b - Institutionalised Partnerships based on Article 187 TFEU

Article 187 of the TFEU allows the Union to set up joint undertakings or any other structure necessary for the efficient execution of EU research, technological development and demonstration programmes. This type of Institutionalised Partnership brings together a stable set of **public and private partners** with a strong commitment to taking a more integrated approach and requires the set-up of a dedicated legal entity (Union body, Joint Undertaking (JU)) that carries full responsibility for the management of the Partnership and implementation of the calls. Different configurations are possible:

- Partnerships focused on creating strategic industrial partnerships where, most often, the partner organisations are represented by one or more industry associations, or in some cases individual private partners;
- Partnerships coordinating national ministries, public funding agencies, and governmental research organisations in the Member States and Associated Countries;
- Or a combination of the two: the so-called tripartite model.

Participation of non-associated Third Countries is only possible if foreseen in the basic act and subject to conclusion of an international agreement.

2.3 Overview of the methodology adopted for the impact assessment

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines²⁰ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This also integrates **key selection criteria for European Partnerships**.

Box 2 Summary of European Partnerships selection criteria²¹

- **Effectiveness** in achieving the related objectives and impacts of the Programme;
- **Coherence** and synergies of the European Partnership within the EU R&I landscape;
- **Transparency & openness** as regards the identification of priorities and objectives and the involvement of partners & stakeholders from the entire value chain, backgrounds & disciplines;
- Ex-ante demonstration of **additionality** and **directionality**;
- Ex-ante demonstration of the partners' **long term commitment**.

2.3.1 Overview of the methodologies employed

In terms of **methods and evidence used**, the impact assessments draw on an external study covering all candidate Institutionalised European Partnerships in parallel to ensure a high level of coherence and comparability of analysis, in addition to an horizontal analysis.²² For

²⁰ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

²¹ For a comprehensive overview of the selection criteria for European Partnerships, see Annex 6.

²² Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Study for the European Commission, DG Research & Innovation

all initiatives, the understanding of the overall context of the candidate institutionalised European Partnerships relied on desk research, including among others the lessons learned from previous partnerships. This was complemented by the analysis of a range of quantitative and qualitative evidence, including evaluations of past and ongoing initiatives; foresight studies; statistical analyses of Framework Programmes application and participation data, and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options, as described below. Public consultations (both open and targeted) supported the comparative assessment of the policy options. For each initiative, up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition, the analysis was informed by the results of the Open Public Consultation run between September and November 2019, the consultation of Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of initiatives.

A more detailed description of the methodology and evidence base that were mobilised, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

2.3.2 Method for identifying the preferred option

The first step of the assessments consisted in scoping the problems that the initiatives are expected to solve given the overall economic, technological, scientific and social context, including the lessons to be learned from past and ongoing partnerships on what worked well and less well. This supported the identification of the objectives of the initiative in the medium and long term with the underlying intervention logic – showing how to get there.

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has then been adapted to introduce “**key functionalities needed**” - making the transition between the definition of the objectives and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1). In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options while allowing at the same time a structured comparison of the options not only as regards their effectiveness, efficiency and coherence, but also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)²³.

²³ The criterion on the ex-ante demonstration of partners' long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made compared to the baseline. Therefore, for each of these aspects the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. This includes the discontinuation costs/benefits of existing implementation structures when relevant. The policy options are then scored compared to the baseline with a + and – system with a two-point scale, to show a slightly or highly additional/lower performance compared to the baseline. A scoring of 0 of a policy option means that it would deliver as much as the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options²⁴.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach²⁵ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account²⁶. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs

²⁴ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

²⁵ For further details, see Better Regulation Toolbox # 57.

²⁶ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

of each candidate initiative.²⁷ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership the costs of preparation and implementation increase only marginally compared to the baseline (<1%), but lead to an additional R&I investment of at least the same amount than the Union contribution²⁸ (efficiency of 98% for the overall investment).
- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2,3 times the Union contribution²⁹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution³⁰. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution³¹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0		↑↑		
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0		↑↑		
Ex-ante Impact Assessment for partnership		0		↑↑↑	
Preparation of EC proposal and negotiation		0		↑↑↑	
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0		↑		

²⁷ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

²⁸ Minimum contributions from partners equal to the Union contribution

²⁹ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

³⁰ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

³¹ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC	0				↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**)³². In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

For the **identification of the preferred option**, the scorecard analysis builds a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

As a last step, the alignment of the preferred option with key criteria for the selection of European Partnerships is described, reflecting the outcomes of the ‘**necessity test**’.³³ The monitoring and evaluation arrangements are concluding the assessment, with an identification of the key indicators to track progress towards the objectives over time.

2.4 Horizontal perspective on candidate Institutionalised European Partnerships

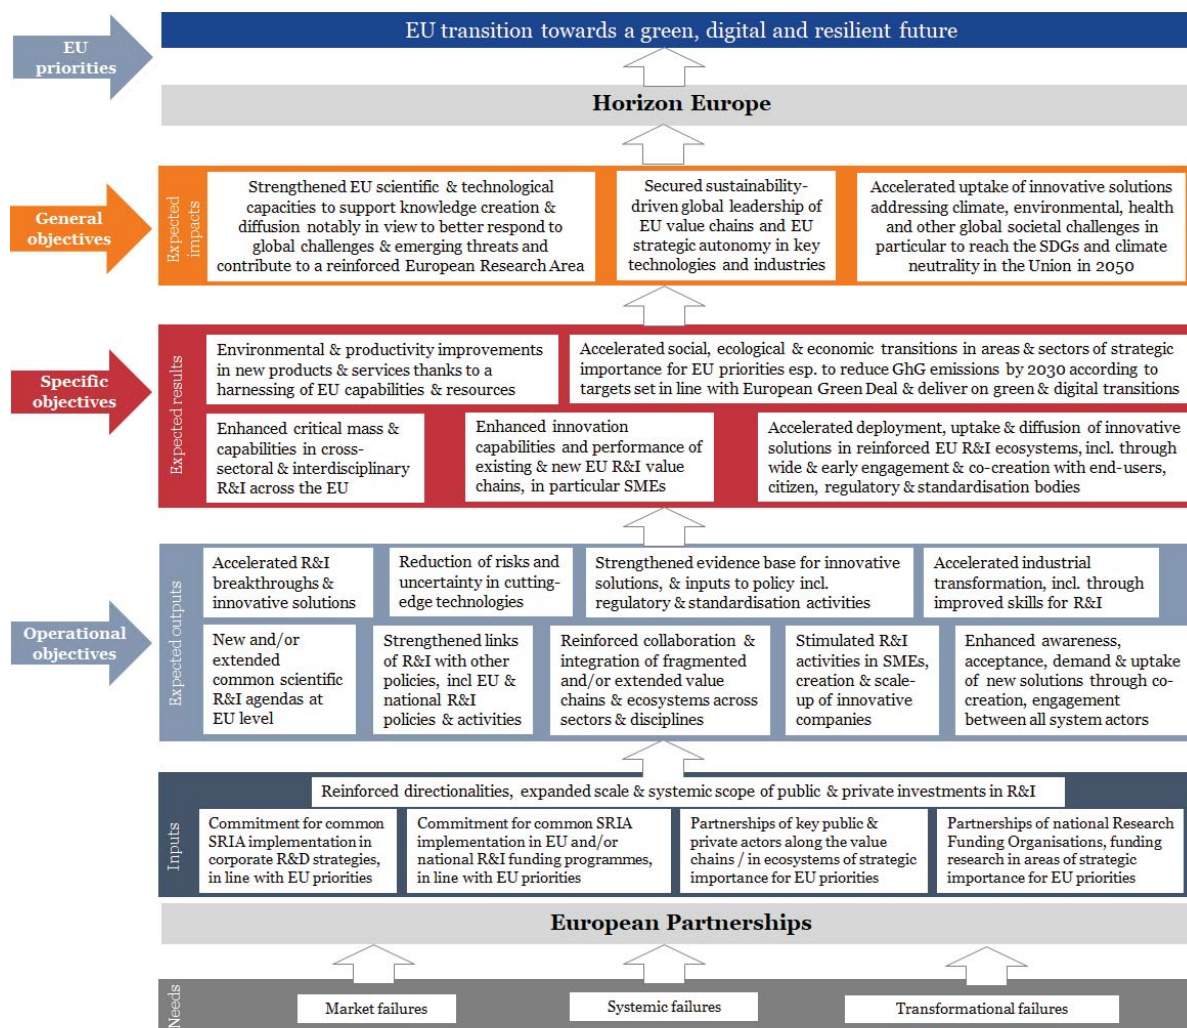

2.4.1 Overall impact orientation, coherence and efficiency needs

The consolidated **intervention logic** for the set of candidate Institutionalised European Partnerships in the Figure below builds upon the objectives as reported in the individual impact assessments.

³² More details on the methodology can be found in Annex 4.

³³ Certain aspects of the selection criteria will be further addressed/ developed at later stages, notably in the context of preparing basic acts (e.g. Openness and Transparency; Coherence and Synergies), in the Strategic Research and Innovation Agendas (e.g. Directionality and Additionality), and by collecting formal commitments (Ex-ante demonstration of partners’ long-term commitment).

Figure 5 – Overall intervention logic of the European Partnerships under Horizon Europe

Source: European Commission, DG Research & Innovation, Unit A2 Programme Analysis and Regulatory Reform, adapted from Technopolis Group (2020)

When analysed as a package the 12 candidate Institutionalised European Partnerships are expected to support the achievement of the European policy priorities targeted by Horizon Europe by pursuing the following joint general objectives:

- Strengthening and integrating EU scientific and technological capacities to support knowledge creation and diffusion notably in view to better respond to global challenges and emerging threats and contribute to a reinforced European Research Area;
- Securing sustainability-driven global leadership of EU value chains and EU strategic autonomy in key technologies and industries; and
- Accelerate the uptake of innovative solutions addressing climate, environmental, health and other global societal challenges contributing to Union strategic priorities, in particular to reach the Sustainable Development Goals and climate neutrality in the Union in 2050.

In terms of specific objectives, they jointly aim to:

- Enhance the critical mass and scientific capabilities in cross-sectoral and interdisciplinary research and innovation across the Union;
- Accelerate the social, ecological and economic transitions in areas and sectors of strategic importance for Union priorities, in particular to reduce greenhouse gas

emissions by 2030 according to the targets set in line with the European Green Deal, and deliver on the green and digital transition;

- c) Enhance the innovation capabilities and performance of existing and new European research and innovation value chains, in particular SMEs;
- d) Accelerate the deployment, uptake and diffusion of innovative solutions in reinforced European R&I ecosystems, including through wide and early engagement and co-creation with end-users, citizen and regulatory and standardisation bodies;
- e) Deliver environmental and productivity improvements in new products and services thanks to a harnessing of EU capabilities and resources.

In terms of their operations, taking an horizontal perspective on all initiatives allows for the identification of further possible collective efficiency and coherence gains for more impact:

- **Coherence for impact:** The extent and speed by which the expected results and impacts will be reached, will depend on the scale of the R&I efforts triggered, the profile of the partners involved, the strength of their commitments, and the scope of the R&I activities funded. To be fully effective it comes out clearly that future partnerships need to operate over their whole life cycle in full coherence with their environment, including potential end users, regulators and standardisation bodies. This relates also to the alignment with relevant EU, national or regional policies and synergies with R&I programmes. This needs to be factored in as of the design stage to ensure a wide take-up and/or deployment of the solutions developed, including their interoperability.
- **Collaboration for impact:** Effectiveness could also be improved collectively through enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems. An adequate governance structure appears in particular necessary to ensure cross-fertilisation between all European Partnerships. This applies not only to initiatives where similar R&I topics are covered and/or the same stakeholders involved or targeted, but also to the interconnections needed between the ‘thematic’ and the ‘vertical’ Partnerships, as these are expected to develop methodologies and technologies for application in EU priority areas. Already at very early stages of preparing new initiatives, Strategic Research and Innovation Agendas and roadmaps need to be aligned, particularly for partnerships that develop enabling technologies that are needed in other Partnerships. The goal should be to achieve greater impacts jointly in light of common challenges.
- **Efficiency for impact:** Potential efficiency gains could also be achieved by joining up the operational functions of Joint Undertakings that do not have a strong context dependency and providing them through a common back-office³⁴. A number of operational activities of the Joint Undertakings are of a technical or administrative nature (e.g. financial management of contracts), or procured from external service providers (e.g. IT, communication activities, recruitment services, auditing) by each Joint Undertaking separately. If better streamlined this could create a win-win situation for all partners leading to better harmonization, economies of scales, and less complexity in supervision and support by the Commission services.

2.4.2 Analysis of coherence of the overall portfolio of candidate initiatives at the thematic level

Looking at the coherence of the set of initiatives at the thematic level, the “**digital centric**”

³⁴ See Annex 6 for an overview of key functions/roles that could be provided by a common back office.

initiatives have a strong focus on supporting the digital competitiveness of the EU ecosystem. Their activities are expected to improve alignment and coordination with Member States and industry for the development of world-competitive EU strategic digital technology value chains and associated expertise. Addressing the Key Digital Technologies, the 5G and 6G connectivity needs as part of a Smart Networks and Services initiative and the underlying supercomputing capacities through a European High Performance Computing initiative present potential for synergies that can be addressed through cooperative actions (e.g. joint calls, coordinated support activities, etc.). They may as well profit from and contribute to Partnerships envisaged for Photonics, AI, data, robotics, Global competitive space system and Made in Europe, together with the EIT Digital. Synergies between these initiatives and several programmes (Digital Europe and Connecting Europe as well as cohesion programmes) are needed in areas where EU industry has to develop leadership and competitiveness in the global digital economy. They are expected to impact critical value chains including on sectors where digital is a strong enabler of transformation (health, industrial manufacturing, mobility/transport, etc.).

The **transport** sector face systemic changes linked to decarbonisation and digitalisation. Large scale R&I actions are needed to prepare the transition of these complex sectors to provide clean, safer, digital and economically viable services for citizens and businesses. Past decades have shown that developing and implementing change is difficult in transport due to its systemic nature, many stakeholders involved, long planning cycles and large investments needed. A systemic change of the air traffic network through an Integrated Air Traffic Management initiative should ensure safety and sustainability of aviation, while a Clean Aviation initiative should focus on the competitiveness of tomorrow's clean aircrafts made in Europe. The initiative for Transforming Europe's rail system would comprehensively address the rail sector to make it a cornerstone in tomorrow's clean and efficient door-to-door transport services, affordable for every citizen as well as the most climate-friendly mode of transport for freight. Connected and Automated Mobility is the future of road transport, but Europe is threatened to fall behind other global regions with strong players and large harmonised markets. The initiative Safe and Automated Road Transport would bring stakeholders together, creating joint momentum in digitalising road transport and developing new user-based services. Stronger links and joint actions will be established between initiatives to enable common progress wherever possible. The Clean Hydrogen initiative would be fundamental to that regard. Synergies would also be sought with partnerships driving the digital technological developments.

To deliver a deep decarbonisation of highly emitting industrial sectors such as the steel, transport and chemical industries would require the production, distribution and storage of **hydrogen** at scale. The candidate hydrogen initiative would have a central positioning in terms of providing solutions to the challenges for sustainable mobility and energy, but also is expected to operate in synergies with other industry related initiatives. The initiative would interact in particular with initiatives on the zero emission road and water transport, transforming Europe's railway system, clean aviation, batteries, circular industry, clean steel and built environment partnerships. There are many opportunities for collaboration for the delivery and end-use of hydrogen. However, the Clean Hydrogen initiative would be the only partnership focused on addressing hydrogen production technologies.

Metrology, the science of measurement, is an enabler across all domains of R&I. It supports the monitoring of the Emissions Trading System, smart grids and pollution, but also contributes to meeting demands for measurement techniques from emerging digital technologies and applications. More generally, emerging technologies across a wide range

of fields from biotechnologies, new materials, health diagnostics or low carbon technologies are giving rise to demands requiring a world-leading EU metrology system.

The initiative for a **Circular Bio-based Europe** is intended to solve a shortage of industry investments in the development of bio-based products whose markets do not have yet certain long-term prospects. The **Innovative Health Initiative** and **EU-Africa Global Health** address the lack of investments in the development of solutions to specific health challenges. The initiative on **Innovative SMEs** supports innovation-driven SMEs in participating in international, collaborative R&I projects with other innovative firms and research-intensive partners. As a horizontal initiative it is expected to help innovative SMEs to grow and to be successfully embedded in global value chains by developing methodologies and technologies for potential application in the other partnership areas or further development by the instruments of the European Innovation Council.

The description of the interconnections between all initiatives for each Horizon Europe cluster is provided in the policy context of each impact assessment and further assessed in the coherence assessment for each option.

PART 2 - THE CANDIDATE EUROPEAN PARTNERSHIP ON A CIRCULAR BIO-BASED EUROPE

1. INTRODUCTION: POLITICAL AND LEGAL CONTEXT

Europe embarked on its course to become the first climate neutral continent by 2050. The roadmap and series of measures and initiatives to lead this green transition are set out in the European Green Deal³⁵, the Commission's new growth strategy to boost the green economy and protect the environment.

The climate and environmental challenges that Europe is facing are interlinked with and reinforced by unsustainable production and consumption patterns, overexploitation of natural resources, ecosystem degradation, biodiversity loss and dwindling availability of critical raw materials³⁶. Research and innovation are fundamental drivers that can turn these complex and multi-faceted challenges into economic and environmental opportunities that are also inclusive and just. They can provide for disruptive innovations that trigger societal transitions, breakthrough technologies that open new market opportunities, as well as sustainable and circular solutions that address environmental challenges.

The bioeconomy – and notably its industrial part ‘the bio-based industry’ - have a strong role to play in delivering environmental and climate neutral solutions through bio-based innovation. Beyond decreasing EU dependency on and accelerating the substitution of non-renewable fossil raw materials and mineral resources, and providing low-toxicity bio-based alternatives, the bio-based industry has the potential to create value from local feedstock and deliver jobs, economic growth and development not only in urban areas but also in rural and coastal territories where biomass is produced.

Definition of the bioeconomy³⁷

“The bioeconomy covers all sectors and systems that rely on biological resources (animals, plants, micro-organisms and derived biomass, including organic waste), their functions and principles. It includes and interlinks: land and marine ecosystems and the services they provide; all primary production sectors that use and produce biological resources (agriculture, forestry, fisheries and aquaculture); and all economic and industrial sectors that use biological resources and processes to produce food, feed, bio-based products, energy and services.³⁸”

Definition of bio-based industry³⁹

The bio-based industry is the part of economy formed by companies that use biological input (feedstock) to produce material, products and services. The biological input can be the biomass extracted from natural environment and purpose grown biomass (e.g. from agriculture and forestry, marine, fisheries and aquaculture), as well as different forms of biological waste, side streams and residues (e.g. by-products, rejects and waste from agriculture, wood processing, food production, industrial biological waste or municipal biological waste). Bio-based industry can produce bulk materials (continuous industry) or

³⁵ COM(2019) 640 final, The European Green Deal.

³⁶ COM(2017) 490 final, 2017 list of Critical Raw Materials for the EU

³⁷ COM(2018) 673 final, EU Bioeconomy Strategy (2018).

³⁸ Biomedicines and health biotechnology are excluded.

³⁹ In this impact assessment biomedicines and health biotechnology is excluded from the definition of the bio-based industry in line with the EU Bioeconomy Strategy,

specific products⁴⁰ (discrete industries). Bio-based industries operate in many manufacturing sectors⁴¹.

Definition of bio-based innovation

Bio-based innovation is a novel concept, technology, process, material or product based on the use and transformation of biological input. The benefits of bio-based innovation include one or more of the following: increased energy or material efficiency of production process, new properties of produced material or product, ability to use and valorise waste, and elimination of pollution.

Building on the scientific advances in life-sciences and biotechnology, the area of bio-based innovation is growing fast. This is particularly the case in certain areas of application, such as health, agriculture, nutrition and specialty materials and consumer products, where there are expectations of high economic returns for the industry. However, the scientific advance in biology can be applied more broadly and introduce bio-based innovative solutions in most manufacturing sectors and thus contribute to the needed climate and environmental transition. The bio-based industry is now expected to invent and bring further to the market a wide set of climate- and environment-friendly circular and sustainable bio-based solutions for the production of basic chemicals and materials, plastics, packaging, construction products, textile and other goods with high material use.

To exploit the full potential of the bio-based industry, improved technologies and new transformation processes still need to be developed, tested in the real-life environment and brought to the market. Life sciences and biotechnologies, including industrial biotechnology and engineering (or synthetic) biology as well as digital, chemical, microbial, enzymatic and electrochemical technologies offer new opportunities for improvement of technologies and processes used by the bio-based industry⁴². These technologies are often platform technologies that can be applied in a number of sectors such as agriculture, foods and feed, pharmaceuticals⁴³, chemicals and materials, energy etc. Some segments of biotechnology are still in their infancy (e.g. marine biotechnology), while others (e.g. industrial biotechnology) are far more advanced and already at the heart of the bio-based industry (e.g. use of enzymes in biomass processing in biorefineries). Yet even in the latter case, the focus on new types of feedstock for processing requires intensive R&I effort to develop more efficient biotechnological processes (e.g. specific enzymatic mixtures or pre-treatment of biomass).

⁴⁰ Bio-fuels are bio-based products and in a broader sense, bio-fuel production is a segment of the bio-based industry. However, the bio-fuel production is excluded from the scope of the proposed R&I initiative as this segment operates in a very different policy and market context from the rest of the industry. The biofuel sector is highly regulated and markets are strongly affected by economic incentives. R&I in biofuel is facing a different set of issues as there are separate R&I and investment programmes and instruments for research in biofuels. From the technological point of view, bio-fuel innovation is still implicitly included in the scope of the proposed initiative, as the technology for production of biofuel is similar to the technology to produce many other bio-based materials. An example is the production of ethanol from agricultural residues through biorefining. This ethanol can be used as bio-additive to fuel or as a feedstock for the chemical industry. Also, the sustainability aspects of the bio-based industry are applicable for biofuels. As a result, the biofuel segment will benefit from this initiative.

⁴¹ In this impact assessment report the term ‘sector’ is interpreted as a part of economy that is defined by the product or service provided. For example there is the “manufacturing of chemicals and chemical products” sector (NACE code C20) which covers all industrial manufacture of chemicals. Within this sector there are companies that use abiotic materials as an input for production of chemicals as well as companies using biological input. The companies using the biological input will be considered as the bio-based industry within the chemicals sector. There is no single NACE code that would be assigned to the bio-based industry.

⁴² OECD, Meeting Policy Challenges for a Sustainable Bioeconomy, Paris, 2018.

⁴³ While biotechnology is at the heart of bio-based processes, health biotechnology and biological medicines are not included in the European Union’s (EU) bioeconomy definition.

The bio-based industry is a capital intensive, high-risk investment area that is facing technological, regulatory and market challenges that cannot be tackled by any Member State alone. It requires concerted action by a wide range of stakeholders and the mobilisation of public and private funding to create a supportive ecosystem that can trigger a green transition. Therefore, since 2014, the European Union supports the ‘Bio-based Industries Joint Technology Initiative’ (BBI Joint Undertaking or BBI JU) -- a public-private partnership between the EU and the Bio-based Industries Consortium⁴⁴. It is aimed at increasing research and innovation investment in the development of a sustainable bio-based industry in Europe. The interim evaluation of the BBI JU⁴⁵ underlined its structuring and mobilising effect on the bio-based industry, but also made recommendations for improvement as regards the scope of its activities, the synergies with other initiatives, and the involvement of stakeholders (e.g. NGOs, brand owners, citizens) and actors such as Member States, regions and municipalities. Since then, the socio-economic, scientific, technological, and political contexts have further evolved putting new demands on these types of partnerships. In particular, the analysis of participation highlighted the need to increase engagement of key actors (e.g. primary biomass producers in bio-based value chains, investors, regions). Furthermore, following the COVID-19 crisis, the bio-based industry is considered a strong catalyst and enabler to drive the green transition to a more resilient and environmentally sustainable EU economy, which is a critical opportunity for the Green Deal and the European recovery plan Next Generation EU⁴⁶ - and therefore this has to be reflected in any future initiative.

Based on lessons learned from past experience⁴⁷ and new and emerging needs, this Impact Assessment document assesses which of the available instruments under Horizon Europe would be the most effective and efficient to focus, structure and align joint European research and innovation activities in bio-based industrial systems to deliver on EU priorities.

Stakeholder opinion

Some 67% of the 1755 respondents (including industry, academic and research institutions, public authorities and NGOs) to the Open Public Consultation consider that the scope and coverage proposed for this candidate Circular Bio-based Europe partnership are right and appropriate in terms of technologies and research areas covered, geographical and sectoral scope, proposed types of partners and range of activities.

1.1 Emerging challenges in the field

Global challenges like climate change, land and ecosystem degradation, coupled with a growing population are forcing us to seek new ways of producing and consuming that respect the ecological boundaries of the planet^{48,49}.

Unsustainable production and consumption patterns are on the rise including the use of fossils, minerals and metals with high climate and environmental footprint⁵⁰. The

⁴⁷ Importantly, additional sources of evidence since the BBI JU interim evaluation (2017), such as BBI JU Annual Activity Reports 2018 and 2019.

⁴⁸ COM(2018) 673 final, EU Bioeconomy Strategy (2018).

⁴⁹ COM(2019) 22 final, Reflection paper towards a sustainable Europe.

⁵⁰ Approximately one quarter of global GHG emissions is caused by material production (from: Material Economics (2019) Industrial Transformation 2050)

McKinsey Global Institute⁵¹ estimates that 60% of global material input can be made using biological means. Yet this is not happening. There is thus an enormous but not fully tapped potential for substitution of abiotic fossil materials with bio-based material which can offer the same functionality, or even have novel properties unachievable by conventional materials and products, such as lower toxicity or better functional characteristics.

The growing European bio-based industry relies on various types of biomass as main input. **This feedstock availability is not constant and quality is not homogenous by default.** It can be affected among others by geography, climate and soil conditions, seasonality, logistical issues, competing uses of biomass for other applications such as energy production, certification requirements and type of feedstock (primary produce or secondary resources: biowaste, residues, etc.). These elements can lead to large price fluctuations and even unavailability of feedstock, which is an important constraint for the functioning of European bio-based industry. In such cases, if the bio-based industry cannot use alternative feedstock or increase feedstock efficiency, price increases or volatility end up reducing competitiveness and demand for bio-based products compared to fossil-based industry alternatives. As a result, bio-based products may become **more expensive than their fossil-based substitutes**, which is a significant structural competitive disadvantage for bio-based industry⁵².

In addition, biomass is the most wasted material – more than one quarter or about 600 megatons of biomass ends up as waste every year, out of which 60 megatons is food waste⁵³ and 88 megatons is municipal waste⁵⁴. **Only about 25% of this resource is collected and recycled**, showing the high level of opportunities for capturing the economic value and reducing environmental impact of biological waste. Higher utilisation of biological waste as a feedstock would make the bio-based industries more **circular**⁵⁵ and contribute to the EU circular economy transition. However, low grade, non-homogenous waste with impurities is difficult to process with the current technologies so the ability of the bio-based industry to use bio-waste feedstock, especially in higher value products accepted by consumers, is a persisting R&I challenge for the future.

Climate change puts pressure on the need to decrease carbon emissions from industry, and bio-based industrial systems are intrinsically carbon efficient. Living organisms and in particular plants bind carbon from the air, soil or water, and turn it into biomass. If this biomass is converted into materials, the carbon stocks contained therein is sequestered for the time until the material is combusted or degraded so that carbon is released back to the atmosphere. However, the overall carbon efficiency of bio-based industrial production systems depends on the amount and form of energy they use in the whole production system including production of biomass, transport, processing, and so on, and can be measured by a whole ‘life cycle assessment’ (LCA). This is why some industrial systems can be demonstrably very carbon efficient and contribute to climate mitigation while others may even emit more carbon than they bind. For instance, in the biofuel sector some older

⁵³ Bio-based Industry Consortium and Zero Waste Europe (2020): Bio-waste generation in the EU: Current capture levels and future potential

⁵⁴ COM (2010) 235 Communication from the Commission to the Council and the European Parliament on future steps in bio-waste management in the European Union

⁵⁵ According to the EC Expert Group on Circular Economy F EIB (2017): Access-to-finance conditions for Investments in Bio-Based Industries and the Blue Economy, the bio-based industry can become circular by: using sustainably sourced renewable biomass as the feedstock, using the biological waste as the feedstock, or by producing materials/products that can be used in circular way (EC Expert Group on Circular Economy Finance (2020): Categorisation System for Circular Economy)

biorefineries in the EU do not meet the current legal requirement for GHG reduction and can actually emit more carbon emissions than equivalent fossil based operations⁵⁶. The scientific community agrees that the carbon efficiency of certain bio-based industrial systems can be improved significantly.

Socio-economic and environmental pressures push for more resilient, circular and local industrial processes. The bio-based industry can make the EU economy more circular and locally sourced. Bio-based technology can use domestic sustainably produced biomass or use local biological waste or residues from agriculture and forestry, industrial processes and municipal waste.

The **recovery from the economic crisis** caused by the Covid-19 pandemic further demonstrates the need for structural changes that will make the EU economy more resilient to future shocks. The bio-based industry can contribute to the economic recovery and maintain high growth for an extended period. As the bio-based industry uses domestic resources, e.g. the biological waste, it makes this industry more resilient to external crises and fluctuation in availability and cost of raw materials. It can bring jobs to economically depressed areas that may be affected by the crisis disproportionately without leaving certain groups or regions behind⁵⁷ by providing additional income to those who produce biomass in rural and depressed regions that typically do not benefit from industrial development. This **potential can however be undermined by the unequal capacity for bio-industrial activity in different regions.** The challenge is to ensure the development of bio-industrial activity in those parts of Europe where there are suitable conditions for bio-based industrial activities but insufficient capacity, e.g. in Central and Eastern Europe⁵⁸. This particular issue correlates with the policy support given by some EU Member States, demonstrated by the presence or absence of national Bioeconomy strategies⁵⁹.

The overall challenge for the EU bio-based industry to grow in an environmentally sustainable way and deliver jobs and income to rural and low-income regions is not only a concern for the economic actors involved. It is in the public interest that the bio-based industry delivers on its potential to address the societal problems of climate change, resource efficiency and socially fair transition. As research and innovation are fundamental enablers for the bio-based industry, R&I investment in bio-based industrial systems is both in the private and public interest, provided that there are effective safeguards that public policy goals will be pursued by joint activities.

The current state and pace of development is however insufficient for the bio-based industry to play its potential role in the immediate future. The bio-based industry is not yet ready for radically increased investment in the next decade as there are persistent technology, market and policy risks preventing the bankability of bio-based projects. In the context of the post-Covid-19 economic recovery, there is also a risk that unprepared sectors or market players will not be in a position to absorb the investment that could be made available through recovery policies. As a result, this investment is likely go into the conventional industries, thus cementing the unsustainable situation.

⁵⁹ Issue identified by the BBI JU Interim Evaluation (2017). See Section 1.2 below for further details on national strategies.

1.2 EU relative positioning in the field⁶⁰

The relative positioning of the bio-based industry and bio-based innovation can be analysed from different perspectives: the recent development and the current performance of the bio-based industry that indicates how well the EU exploits the potential of the industry based on past innovation; and the level of investment in bio-based industry, the intensity of R&I activities and the development of supporting policies that indicate how the bio-based industry will grow and exploit the potential in the future. This chapter will take both perspectives (within the limits of data availability) comparing the EU to global competitors as well as comparing the situation between different EU Member States.

The EU bio-based industry claims the leadership position in the world⁶¹. The industry has the annual turnover of 700 billion Euro and employs 3.6 million employees (based on 2016 data that do not reflect the impact of Covid-19 crisis)⁶². This is the result of 17% growth over the period 2008-2016 including the economic slowdown in 2009 and 2010. The fastest growing segments of bio-based industry were pharmaceuticals and chemicals. For example the production of bio-based chemicals grew by 33% in volume (from 15 to 20 megatons) and 40% in value (from 20 to 28 BEUR) in the same period. The bio-based industry also improves its position within traditional sectors, i.e. it grows faster than the rest of the industry. For example the share of bio-based industry in the chemicals sector grew from 5% in 2008 to 7% in 2016.

Within the EU, four Member States – Germany, Italy, France and Spain -- represent more than half of the bio-based industrial activity, both from the turnover and employment perspective⁶³. In terms of labour productivity Belgium, Sweden, Denmark, Finland and the Netherlands are the leading Member States⁶⁴. There are 2,362 biorefineries⁶⁵ (facilities processing biomass for product manufacturing) in Europe. The Member States where biorefineries are most present are Germany (close to 600), France, Italy, Sweden and Finland. The Central and Eastern European EU Member States lag behind in terms of turnover, jobs, labour productivity and the number of industrial facilities. Figure 7 below shows specifically the distribution in Europe of bio-based facilities identified as smaller size plants which did not yet reach the commercial phase, including pilot, demo and R&D facilities, based on the distribution in terms of product categories.

⁶⁰ The relative position of the bio-based industry and bio-based innovation is not yet well described due to the lack of detailed data. The bio-based industry cut across the sectoral taxonomy and other statistical categories. Methodologies in different studies differ and provide incomparable results. Also the international comparison is affected by different definitions of bio-based industry applied in national statistical systems.

⁶¹ Bio-based Industry Consortium (2018): A new EU bioeconomy strategy and action plan: Calling for tangible action to scale up the circular bioeconomy

⁶⁴ Ronzon T. et al. (2020): Developments of Economic Growth and Employment in Bioeconomy Sectors across the EU, Sustainability 2020 vol. 12

⁶⁵ European Commission Joint Research Centre, DataM dashboard on Bio-based industry and biorefineries, <https://datam.jrc.ec.europa.eu/datam/perm/news/666>

Figure 7 Pilot, demo and R&D bio-based plants across the EU

Source: European Commission Joint Research Centre (2020)⁶⁶,

At global level the main competitor to the EU bio-based industry is the bio-based industry in the USA, China and Brazil⁶⁷. The bio-based industry generated added value of 400 billion USD and employed 4 million employees in 2013⁶⁸ and the industry was expected to grow fast due to market drivers and proactive policies (tax credits, public procurement, etc.) with expected employment of 5.3 million in 2020. The direct comparison is impossible due to statistical categorisation difference but the most comparable segment – bio-based chemicals – seems to similar dynamics than the EU one with annual growth of 12% in 2014⁶⁹ compared to 11% growth in the EU in 2015.

In the fast growing bio-based industry it is important to understand those factors that will affect the growth in the future. These factors include investment in bio-based industry infrastructure (e.g. biorefineries), intensity of research and innovation activities and the development of policies driving the growth (e.g. economic incentives).

Concerning the level of **investment** the total investment in bio-based industry is not available but one of its representative segment – the bio-based chemicals – attracted 9.2

⁶⁶ Parisi, C., Distribution of the bio-based industry in the EU, Publications Office of the European Union, 2020, ISBN 978-92-76-16408-1, doi:10.2760/745867, JRC119288

⁶⁷ The comparison will be limited to comparison with the US as the industrial structure and statistical systems seems to be most comparable to the EU one.

⁶⁸ US Department of Agriculture (2015): An Economic Impact Analysis of the U.S. Biobased Products Industry

⁶⁹ Grand View research (2020): Bio-based Platform Chemicals Market Size, Share & Trends Analysis Report

billion USD globally from 2010 to 2015⁷⁰. The distribution of this investment is approximately equal for the four global regions (Europe, North America, South America and Asia) with the specific focus in Europe and the US on R&I and pilot facilities, while in Asia and South America investment goes more into commercial production plants. The recent investment in all four regions resulted in a comparable production capacity. The remarkable difference is the investment of venture capital funds that is predominantly attracted (82%) by the US market.

The intensity of R&I activities in the bio-based innovation area can be measured by proxy indicators including R&I spending, scientific publications and patents. The **private investment** in biotechnology – the key R&I area for the bio-based innovation – is dominated by the US with more than 50 billion USD in 2017 compared to estimated 15 billion in the EU⁷¹. As a percentage of biotech R&I on the total private R&I expenditure the US leads before all EU Member States except Belgium (13% in the US and 32% in Belgium). The **public expenditure** in biotech R&I in the EU Member States is estimated to 3.1 billion Euro.

In **scientific publications** in the bio-based area, cumulative statistics for EU countries show EU leadership at global level followed by the US and China⁷². However the US leads on the **number of patents** in the biotechnology area (37% compared to 24% of the EU). The EU is losing its position in patenting also to countries like China and Korea.

Figure 8 Revealed EU28 technological advantage in biotechnologies based on patents, 2005-07 and 2015-17

Source: OECD, STI Micro-data Lab: Intellectual Property Database, Index based on IP5 patent families, fractional counts <http://oe.cd/ipstats>, October 2019. The revealed technological advantage index is calculated as the share of country (or economy) in biotechnology patents relative to the share of country (or economy) in total patents. Only countries and economies with more than 100 patents per period are included in the figure.

⁷⁰ Dammer L. et al., *Current situation and trends of the bio-based industries in Europe. Pilot study by nova-Institute for BBI-JU*, 2017.

⁷¹ OECD (2020): Key biotechnology indicators

⁷² Technopolis (2020), the analysis of the bio-based sector performed for the impact assessment study.

Concerning the **favourable policies** that facilitate the uptake of bio-based innovation and growth in the bio-based industry the EU Bioeconomy Strategy encourages Member States to develop their national Bioeconomy Strategies and other policies to stimulate bio-based industries. Currently, nine EU Member States (Austria, Finland, France, Germany, Ireland, Italy, Latvia, Spain, the Netherlands) have a national strategy while other Member States are involved in macro-regional bioeconomy initiatives (e.g. Denmark, Sweden) or have sub-national/regional strategies (e.g. Belgium)⁷³. Despite their large biomass potential most Central and Eastern European (CEE) countries lag behind in the development of dedicated national Bioeconomy Strategies⁷⁴.

The national and regional Bio-economy Strategies provide an important stimulus for bio-based industry, especially if they include synergies with regional development and agriculture policy, including the utilisation of the EU Regional Development Fund and the Common Agricultural Policy funding to incentivise bio-based industrial development. However, this policy is fragmented as there are national and regional difference in the approach and in some regions such stimuli are missing completely.

Compared to the EU fragmented approach the US has developed a comprehensive approach with effective policy at federal level complemented by policy initiatives at states and regional levels. This policy includes tax incentives (15% tax rebate for bio-based industries), public procurement and labelling policy (BioPreferred Programme), subsidies (USDA Biorefinery Assistance Program) and public investment in R&I activities (e.g. USDA/DoE Biomass research and Development Programme)⁷⁵.

The only policy initiative at the EU level specifically focused on bio-based industry is the ‘Bio-based Industries Joint Technology Initiative’ (BBI Joint Undertaking). Since 2014 the European Union supports this public-private partnership aiming at increasing research and innovation investment in the development of a sustainable bio-based industry in Europe (see the box below).

Box 3 Support for the field in the previous Framework Programmes – key strengths & weaknesses identified

What was/is being done with EU research and innovation funding until now

Dedicated R&I activities related to the bioeconomy have been supported through the Framework Programmes, notably via Horizon 2020 Societal Challenge 2 “Food Security, sustainable agriculture, and forestry, marine and maritime and inland water research and the bioeconomy”. In the years 2014 - 2019 there were 807 grants⁷⁶ signed under this Societal Challenge, which received 2,7 billion EUR of EU contribution (4,93% of Horizon 2020), with total cost of 3,6 billion EUR (5,1% Horizon 2020). This covers traditional (collaborative) projects but also support provided through the ‘Bio-based Industries Joint Technology Initiative’ (BBI Joint Undertaking) under Horizon 2020, which in the same period and under the same Societal Challenge funded 104 projects with 602 million EUR of EU contribution, and 909 million EUR of total costs. Thus, 22% of the EU funding (contribution) in Horizon 2020 Societal Challenge 2 was provided through the BBI JU, and 25% of total costs. In total, the BBI JU EU contribution represented 1,07% of Horizon 2020

⁷³ https://ec.europa.eu/knowledge4policy/visualisation/bioeconomy-different-countries_en

⁷⁴ <https://publications.jrc.ec.europa.eu/repository/bitstream/JRC120324/how-big-is-the-economy.pdf>

⁷⁵ USDA (2015): An Economic Impact Analysis of the U.S. Biobased Products Industry

⁷⁶ Horizon 2020 Dashboard (data accessed on 20 July 2020).

EU contribution (amounting to 56,28 billion EUR), and 1,29% of total costs of Horizon 2020 (amounting to 70,52 billion EUR).

The Bio-based Industries Joint Undertaking (BBI JU) was initiated in 2014⁷⁷ with the aims to attract consistent private investment, promote R&I along whole values chains, to avoid fragmentation and duplication of efforts, and improve coordination in innovation activities of bio-based industries. It has originally been allocated **EUR 975 million** from Horizon 2020, and this sum is planned to be matched by EUR 2.73 billion by industries engaged in the partnership.

In terms of **activities**, the BBI JU partnership focuses on sustainable resource use, especially in resource-intensive and high-impact sectors such as agriculture, textiles, manufacturing and construction, in particular also aiming at local operators, manufacturers, plants and factories. It creates awareness, capacities and appropriate structures in a systemic approach. In addition, it focuses on market-oriented measures, such as engagement of consumers and local communities, cost-competitiveness via enlarging the market volume of bio-based innovation, and social innovation for inclusiveness and reducing overconsumption of resources⁷⁸.

In terms of **participants**, it extends beyond industry actors, and mobilises producers of biological resources from land and sea, public authorities managing local development and environmental protection, scientific communities, and end users. The private partner of the BBI JU is the Bio-based Industries Consortium (BIC), which originally included 35 bio-based companies. Since the setup of the BBI JU, the group of BIC members has been growing to over 250 (of which 150 associated members) entities from across different value chains⁽⁷⁹⁾. Over 80% of them are SMEs – mostly in BIC via regional SME clusters. The members cover the whole value chain, from primary production to the market, across multiple and diverse sectors. BIC associated members include research and technology organisations, universities, European associations and organisations, European technology platforms, public institutions, regional organisations and private banks.

What has or is being achieved so far

One of the unique features of the BBI JU initiative has been to foster the closer collaboration between the scientific community and industry, ascending the scale of Technology Readiness Level (TRL) and thus enabling a swifter move towards innovation mentioned in the Strategic Innovation Research Agenda 2017⁸⁰. The scientific community mobilisation is evidenced by the 28.4% participation level of universities and research centres in the BBI JU projects. It is further confirmed by the annual survey directed to the BBI JU project coordinators⁸¹: according to the projects' reports, 80% of them contribute to knowledge creation, 79% contribute to increasing the academia-industry cooperation, and more than half contribute to the building of scientific community networks and to technology transfer. With regard to the mobilization of the SME community, the BBI JU has been very successful, with 41% of beneficiaries of BBI JU projects being SMEs, and 35% of funding

⁷⁷ Council Regulation (EU) 560/2014 amended by Council Regulation (EU) 2018/121 <https://www.bbi-europe.eu/>

⁷⁸ <https://www.bbi-europe.eu/>

⁷⁹ An overview of BIC's current membership, including information about the type of membership (industry or associate, the industrial sector, large or SME, and so on) is available at <https://biconsortium.eu/sites/biconsortium.eu/files/documents/BIC%20members%20list%20January%202020.pdf>.

⁸⁰ KPI 8 (Technology Readiness Level gain) <https://www.bbi-europe.eu/sites/default/files/sira-2017.pdf>

⁸¹ BBI JU Annual Activity Report 2018 ; <https://www.bbi-europe.eu/sites/default/files/bbi-ju-aar-2018.pdf>

dedicated to SMEs. This represents significantly higher level as compared to the 20% target for Horizon 2020.

The expected environmental impact from the projects other than flagships is large as two thirds of them report producing bio-based products with lower GHG emissions⁸². More than half of them expect to contribute to waste reduction, reuse, valorisation or recycling and a decrease of their energy consumption. Finally, 40% of the projects report they expect to improve land use and seven projects report a positive impact on biodiversity, e.g. by developing a sustainable agro-forestry biomass cultivation practice⁸³.

What are the key areas for improvement & unmet challenges?

However, several issues have come up and many lessons were learnt during the implementation of the BBI JU⁸⁴, which have to be taken into account when setting up a new initiative in the area.

Areas for improvement / challenges to overcome:

- **Better synergies with national and regional developments** are needed to develop interconnections between primary producers⁸⁵, regional authorities and biorefinery plants, as well private operators such as brand owners⁸⁶, and taking into account the need for higher circularity and digitalisation⁸⁷, inter-sectorial cooperation⁸⁸, as well as improved participation of EU-13 actors⁸⁹, and integration of territories in need of revitalisation⁹⁰.
- National and regional authorities should be aware of the economic and environmental potential of bio-based solutions and supported in the deployment of bio-based solutions, and an improved exchange of best practices should be put in place⁹¹.
- Programming of the initiative should take into account the public interest, especially critical for long-term impact, and avoiding the risk of industry capture⁹², while considering win-win scenarios for international cooperation⁹³.

⁸² As self-evaluated by the projects. A dedicated evaluation of the Key Performance Indicators and validation of impacts is underway (results expected by 1Q2021).

⁸³ BBI JU Annual Activity Report 2018; <https://www.bbi-europe.eu/sites/default/files/bbi-ju-aar-2018.pdf>. As mentioned, an independent study is ongoing to further assess the Key Performance Indicators for the current JU.

⁸⁴ Commission Staff Working Document - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, {SWD (2017) 339 final}

⁸⁵ Addressing their low participation, as found by the BBI JU 2018 study on agricultural primary biomass producers, and following its specific recommendations.

⁸⁶ BBI JU interim evaluation, recommendation “To include increasingly brand owners and sectors at the interface with consumers with synergies with the existing ones”.

⁸⁷ BBI JU interim evaluation, recommendations “To respond to important emerging trends through future calls that could consider conversion of biogenic CO2 into chemicals and materials as well as digitalization (including big-data analysis and exploitation) as one aspect in Bioeconomy value chains” and “To cover emerging trends, such as synthetic biology and platform technologies (e.g. bioinformatics), in the future BBI work programmes”.

⁸⁸ BBI JU interim evaluation, recommendations “To strengthen the whole value chain approach by a greater participation of end users and customers” and “Efforts should be made to support development of completely new value chains and cross-value chains products and processes”.

⁸⁹ BBI JU interim evaluation, recommendation “To improve the participation of EU-13 MS and Third Countries through a more open programming strategy, which should take into account potentials for growth at macro regional level, also in synergy with other EU initiatives (e.g. Smart Specialisation Strategies, S3).”

⁹⁰ BBI JU interim evaluation, recommendation “To reach out to EU member states and regions with rural or deindustrialized areas for catalysing revitalisation through bio-based industries”.

⁹¹ BBI JU interim evaluation, recommendation “To analyse cases of success in terms of national participation and deliver ‘best practices’ for Member States, offering also mentoring support”.

- At this stage of the current BBI JU initiative, for most BBI-specific KPIs, BBI JU projects are expected to largely exceed the key performance (KPI) targets set for 2020. On one hand, this shows that the BBI JU has contributed to the systemic evolution of the bio-based industry in bridging the gap between innovation and market. On the other, it also hints at the possibility that the **KPIs were not assessed accurately** beforehand, or lacked sufficient ambition⁹⁴.
- The **low focus on biodiversity preservation and enhancement** as part of the pursued biomass value chains has to be improved⁹⁵.
- The private partner of BBI JU, BIC, did not follow up on its **commitment on the financial contribution**⁹⁶ for the operational costs; this led to the need to amend the establishing Regulation (thus generating also additional administrative burden). The amended Model Financial Regulation ensures that the private partner will have to follow up its official financial commitment.
- The way of **reporting** the private partner's in-kind contributions⁹⁷ to operational and additional costs has proven to be complicated and costly. Based on the lessons drawn from current experience, it is possible to mitigate this risk by following the draft legal guidelines on financial commitments, and improving on the measuring the impact⁹⁸.
- The BBI JU Regulation under Horizon 2020 specified that the Union and BIC were to share the JU administrative costs equally. However, a contribution of the grant amount (4%) was asked from beneficiaries that were not members of the JU to cover the private share of these costs. With the adoption of the revised model Financial Regulation and the relevant BBI JU Financial Rules, this practice was put to an end.

Recently, the Corporate Europe Observatory (CEO), a corporate NGO, criticised the existing BBI JU initiative for being captured by private interests⁹⁹. It is legitimate for the public to demand that the public investment in a partnership with the private industry delivers benefits for the society at large. The CEO report also reiterated some of the lessons learned during the implementation of the BBI JU. At the time the BBI JU was established in 2014, it was not subject to an impact assessment process as it is the case for institutionalised partnerships under Horizon Europe. In addition the policy context has changed over the years. Firstly a solid basis was formed based on the interim evaluation report of the BBI JU that covered the years 2014 up to 2016. This was supplemented by information and experience drawn from the publicly available Annual Activity Reports covering the periods

⁹² BBI JU interim evaluation, recommendation "To avoid programming strategies aiming at short term benefit of BIC's specific sectors but rather invest resources in topics able to create wider and long lasting benefits both at multi-sectorial and macro-regional levels".

⁹³ BBI JU interim evaluation, recommendation "To identify win-win strategies for a larger involvement of Third Countries while ensuring the protection of EU industry's interests".

⁹⁴ BBI JU interim evaluation, recommendation "To monitor further progress of BBI JU by an annual comparison between BBI-specific KPIs projected, achieved and accumulated in the corresponding year".

⁹⁵ Issues identified in BBI JU Annual Activity Report 2018 and 2019.

⁹⁶ BBI JU interim evaluation, recommendations "To monitor the effectiveness of the measures implemented for solving the problems related to industrial financial contributions to operational costs and consider possible complementary measures to assure a balanced contribution of the Public and Private members to BBI JU" and "To deliver reports that provide comprehensive description of the actual private and public contributions to BBI JU delivered so far as well as the detailed plan for the delivery of the contribution of the two Partners over the next years"

⁹⁷ BBI JU interim evaluation, recommendations "To monitor the effectiveness of the guidelines for reporting and certification of IKOP and IKAA" and "To deliver reports that provide comprehensive description of the actual private and public contributions to BBI JU delivered so far as well as the detailed plan for the delivery of the contribution of the two Partners over the next years"

⁹⁸ BBI JU interim evaluation, recommendation "To build up metrics and statistical data on the bio-based industries in the EU with annual reporting on economic growth"

⁹⁹ <https://corporateeurope.org/en/BBI-research-and-destroy>

from 2014 to 2019, experience from managing the BBI JU for the past six years and the continuous interaction with stakeholders from the various sectors of the bioeconomy. Combining the changing policy landscape, the learnings from the mid-term evaluation and experience from the BBI JU programme have allowed to adjust the course during the implementation of the programme but also frame from the outset the design of the proposed successor and its governance structure. This is why any future initiative in the area needs to be based on a sound assessment of policy options from the perspective of governance, including in particular the possibility to set adequate safeguards to ensure that the public interests are duly respected in all operations. This is fully in line with the recommendations from the BBI JU interim evaluation referenced above¹⁰⁰. CBE initiative will build on the success of BBI but will have evolved by learning from BBI JU shortfalls.

To conclude the EU comparative positioning, the EU is still a leader, together with the USA, in the field of bio-based industry, with strong growth and increasing share in the economy. However, these traditional leaders are being caught up by China, Brazil and other emerging economies of Asia and South America. Pro-growth initiatives, necessary for ensuring the continuing leadership, including the R&I and proactive policies tend to be fragmented and uneven across the EU.

1.3 EU policy context beyond 2021

The policy related to the bio-based industry has evolved in the last two years to provide a comprehensive frame and define what constitutes the public interest in the development of this industry in the near future. It also gives a sense of directionality for incentives, including for public R&I funding focused on sustainability issues.

The Green Deal communication¹⁰¹ creates the overarching framework for sustainable economic transition and sets the objective of carbon neutrality, resource efficiency and zero pollution. The Green Deal calls for mobilisation of R&I instruments in support of its objectives. It foresees the creation of partnership with the private sector to support R&I on circular bio-based industry¹⁰².

The Clean Planet for All communication¹⁰³ considers the circular economy and bioeconomy as key transition pathways to climate neutrality. It foresees the increased use of sustainable biomass in the form of biofuels and bio-based materials and calls for safeguards that increased demand for biomass will not lead to reduction of natural carbon sinks.

In the Circular Economy Action Plan¹⁰⁴ the Commission commits itself to support the sustainable and circular bio-based industry. The New Industrial Strategy¹⁰⁵ announces the EU support to key enabling technologies including industrial biotechnology. The Sustainable Finance Regulation foresees the development of the taxonomy for circular economy in the near future. In the preparatory work for the taxonomy, the Expert Group on Circular Economy Finance Support categorised bio-based industrial activity as a part of circular economy and proposed a set of performance criteria for substantial contribution to circular economy objectives.

¹⁰⁰ Especially the recommendation “To avoid programming strategies aiming at short term benefit of BIC’s specific sectors but rather invest resources in topics able to create wider and long lasting benefits both at multi-sectorial and macro-regional levels”.

¹⁰¹ COM(2019)640 final

¹⁰² COM(2019)640 final, p18

¹⁰³ COM(2018)773 final, p12, p13

¹⁰⁴ COM(2020)98 final, p6

¹⁰⁵ COM(2020)102 final

The Farm to Fork communication¹⁰⁶ refers to the bio-based economy as the opportunity for farmers and the Commission commits itself to actions to speed up market adoption of bio-based solutions. The Common Agricultural Policy is a powerful instrument for Member States to promote and incentivise the bio-based industry if they consider it as a strategic priority for rural development. The new Biodiversity Strategy¹⁰⁷ announced a plan to assess the availability of biomass for bio-fuel and review the legislative framework¹⁰⁸ as well as set sustainability criteria for use of forest biomass.

The updated EU Bioeconomy Strategy¹⁰⁹ and its Action Plan¹¹⁰, provides the most detailed operational guidelines on the development of the bio-based industry. Its first action area focusses on the strengthening and scaling up the bio-based industry, unlocking investment and markets. It commits the Commission to the following five actions: (1) to mobilise public and private stakeholders in research, demonstration and deployment of sustainable, inclusive and circular bio-based solutions; (2) to launch a Circular Bioeconomy Investment Fund; (3) to study enablers and bottlenecks for the deployment of bio-based innovations; (4) to promote and develop standards, labels and market uptake of bio-based products; (5) to facilitate the development of new sustainable biorefineries; and (6) to develop substitutes to fossil based materials that are bio-based, recyclable and marine biodegradable.

All the above policy objectives and actions have been reflected in the programming documents for the EU R&I programme for the period 2021-2027 – Horizon Europe. The Specific Programme¹¹¹ identifies the priority areas for R&I and indicates the plan to establish an initiative with private partners representing the bio-based industry. The priority agreed between the EU institutions in the Specific Programme are now operationalised in lower level planning documents including the Strategic Plan for 2021-2024 and Work Programme 2021-2022.

The overall policy framework is clear about the strategic role of the bio-based industry in contributing to achieving the EU sustainability objectives and about the direction in which the EU support will be oriented in the coming decade. The R&I programme is charged with the task of facilitating the development and deployment of bio-based innovations that contributes to climate neutrality, resource efficiency, biodiversity, and zero pollution objectives while ensuring also the bio-based industry's contribution to economic growth and regional development. In light of the above, the relevant policy question is thus not whether support in this area is justified but rather what form this support should take to deliver the greatest positive impact for EU investments.

The proposed initiative is among the activities envisaged to implement the Commission's vision for the period beyond 2020 under the Horizon Europe Pillar II, specifically Cluster 6 (Food, Bioeconomy, Natural Resources, Agriculture and Environment). It is one of the European Partnerships foreseen in the Partnership Area of 'sustainable, inclusive and circular bio-based solutions'. As shown below, an initiative for a Circular bio-based Europe would have potential interconnections with other candidate European partnerships such as Safe and Sustainable Food Systems, Accelerating Farming Systems Transition, Rescuing Biodiversity and more.

Figure 9: Potential interconnections between partnership initiatives in the Food, Bioeconomy, Natural Resources, Agriculture and Environment cluster of Horizon Europe

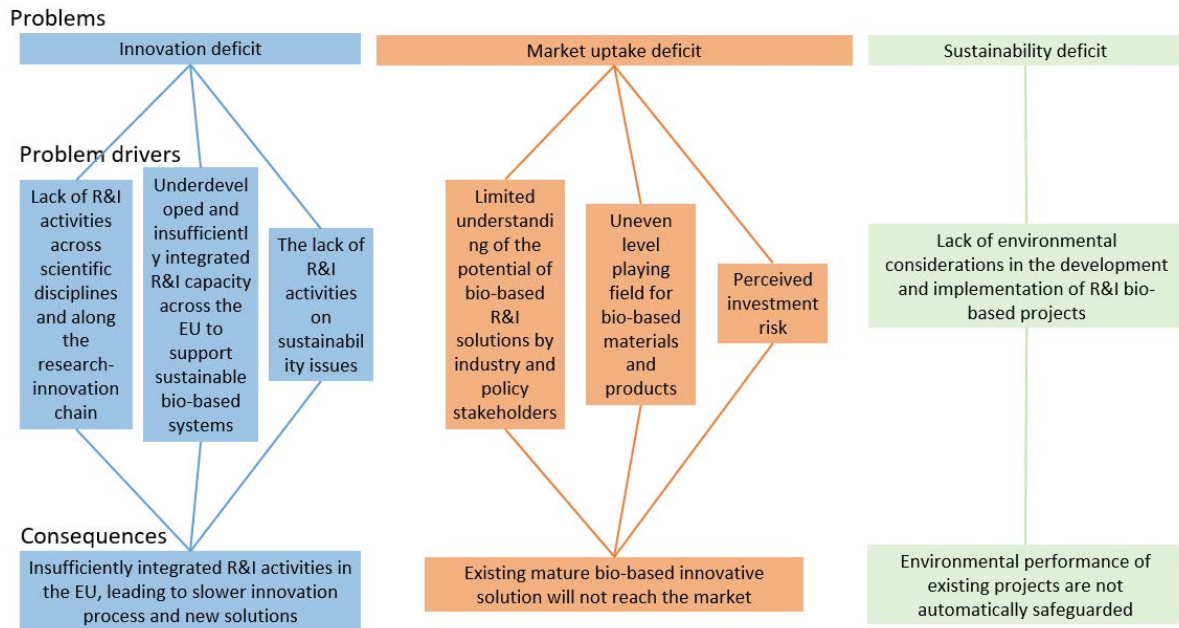

2. PROBLEM DEFINITION

Given the scale of the challenges ahead for the bio-based industry, the current scientific, technological and economic positioning of Europe in the field, and the overarching EU policy context, a set of problems have been identified where EU research and innovation in the circular bio-based industry would have a specific role to play.

The Figure below provides an overview of the problems and problem drivers that will be discussed in this section.

Figure 10: Problem tree for the initiative on Circular Bio-based Europe

2.1. What are the problems?

In general, the EU economy does not exploit bio-based innovation to the full potential and the bio-based industry does not contribute sufficiently to the societal objectives of sustainable and fair growth in the medium and long term. Despite the EU being a world leader in bio-based industry, there are still forgone economic and environmental benefits. As a result, at the moment, the bio-based industry brings a sub-optimal contribution to the carbon neutrality objective of the Green Deal and to the resilient economic recovery objective of the Next Generation EU.

This overarching problem can best be illustrated by focusing on three different strands – insufficient innovation, market failures that prevent mature bio-based innovations from entering markets, and a sustainability challenge to ensure that economically viable bio-based solutions deliver on environmental objectives.

2.1.1. Deficit of cutting-edge science and innovation serving the EU bio-based industry (Innovation deficit)

The bio-based industry is driven by innovation. Although bio-based solutions have been used throughout human history (e.g. food production and preservation, textile, tannery, paper, adhesives, etc.), the modern bio-based industry is based on innovative solutions that enhance the efficacy of natural biological processes. For example, new enzymatic processes or entire bio-based production systems – known as bioroutes – can do one or more of the following: radically improve the efficiency of production processes; enable the use of alternative (more available or cheaper) raw material input; and result in different products with new properties, and increased utility and value.

The biological science is undergoing a revolution that is enabled by advances in molecular biology and computing. The production of biological data is exploding, which is visible in

the accelerating rates of DNA sequencing and the development of “omics”¹¹². This accelerating production of scientific results is a consequence of an acceleration of research using applied biological sciences. The biology science is then combined with physics, chemistry, medical, engineering and IT research to turn the theoretical bio-science concepts into innovative solutions in many areas ranging from medicine to i.a. pharmaceuticals, nutrition, industrial production based on biomachines, and IT based on bio-computing. The scientific community considers as scientifically plausible what used to be inconceivable a short time ago¹¹³.

These advances in biological science can also revolutionise more traditional industrial sectors. Specifically, they can make the existing use of biological resources radically more efficient. An example is squalene, a substance used in vaccines and cosmetics that was traditionally produced from shark liver. Squalene is now produced at industrial scale by an engineered yeast. Bio-based solutions can produce materials that are currently derived from non-renewable abiotic resources, e.g. microorganisms are already being used to produce plastics or bio-based alternatives to cement. Completely new materials or products can be produced by microorganisms as a bio-based optical films to be used in computer displays and flexible electronic circuits.

Stakeholder opinion

57.8% of respondents to the OPC (including industry, academic and research institutions, public authorities and NGOs) indicated that the innovation gap in the EU in translating research results into the development of innovative circular/bio-based products is very relevant. Collaborative R&I projects were also considered as very relevant by a large number of respondents (120 respondents or 59.11%). In particular, a large majority of academics, business associations and EU citizens, and all respondents from public authorities, described collaborative R&I projects as relevant.

Despite the theoretical potential of applying cutting-edge bio-science for radically increased use of biological resources as an input into the material and product economy, innovation in this area is trailing behind innovation in medical, pharmaceutical, nutrition and bioengineering areas. Out of 400 innovation pipelines in bio-science that are considered as scientifically feasible and economically plausible¹¹⁴, the majority of applications is in the areas of health and nutrition. In terms of prospective economic impact of the innovation in the pipeline, these sectors also dominate with 33% of the total bio-based economic impact in the health and 36% in the nutrition sectors respectively. Conversely, innovation in material production represents only 8% of the estimated potential of the emerging innovation. The time of bringing innovation to the market also tends to be shorter for health innovation (5-15) years compared to material innovation (10-25 years), which indicates less intensive activities in testing and demonstration. This innovation deficit problem ultimately results in missing innovation pipelines that could be a basis for future radically improved industrial processes and products and suited to many economic sectors and areas of application.

¹¹² These include for example genomic, epigenomics, proteomics, glycomics, lipidomics, transcriptomic, metabolomics.

¹¹³ Examples of such breakthrough innovations enabled by the biological revolution include individualised gene therapies for genetic diseases, 3D printing of living tissues or organs, neuroprosthetics or Biocomputing (in McKinsey(2020) The Bio revolution)

¹¹⁴ McKinsey 2020: The Bio Revolution

2.1.2. Deficit in uptake of bio-based innovative processes in EU industrial value chains (Market uptake deficit)

In addition to the above, the bio-based industry also faces a problem of limited market uptake for current innovation. Existing and technically and economically viable solutions are not penetrating market at sufficient speed. The potential of biomass produced in the EU remains untapped and a large part of it is wasted¹¹⁵. An indicator of this situation is that in the EU only 10% of the biomass is used in products and only a small part of it enters long lasting material stocks, such as durable and high-performance materials used in construction or automotive sector (e.g. insulation materials, composites). In contrast, more than half of all biomass is used for energy and one quarter of biomass is wasted.

An illustrative example of market uptake deficit is the use of waste from the food industry. This waste is an ideal input in the bio-based industry due to its relative homogeneity¹¹⁶. There is abundance of food waste (30 MT a year) as it is unavoidable in the food production process. With growing food production in the EU, this potential feedstock also grows at a compound annual growth rate of 4.3% from 2019 to 2024^{117,118}. There are a number of food waste processing bio-based technologies that are mature enough for industrial application. These technologies can also produce a wide range of materials and products for which markets exist (see Figure 11). In some cases, the produced chemicals or materials are very valuable, e.g. lycopene (a natural carotenoid with antioxidant and anti-cancer properties) extracted from tomato waste has a market value of 40 000 EUR per kg. The JRC studied the techno-economic feasibility of industrial installations – biorefineries – focusing on the optimisation of the use of this type of feedstock. The JRC study concludes that for four traditional waste streams (orange, potato, tomato and olive) and a limited scope of technologies and produced materials, there is already potential for profitable investment in 189 biorefineries with payback period up to 15 years and in some cases with a return on investment of 9%¹¹⁹. These biorefineries, however, have yet to be constructed and meanwhile this valuable resource – food waste -- is mainly used in low value applications such as combustion or composting and continues to emit methane and/or CO₂ in the atmosphere.

A similar deficit in market uptake of technically and economically feasible bio-based applications exists in other biomass streams, including wood-based and aquatic biomass, and municipal biological waste and wastewater. The EU Bioeconomy Strategy estimated that 300 biorefineries should be constructed in the next decade to tap the existing potential of bio-based systems. This would require a total investment at the level of 50 billion EUR. This estimation does not include the potential of innovation in the low technology readiness stage that can further enlarge the economic opportunities of the bio-based industry.

The picture below illustrates how different kinds of food waste can be processed in a number of value added materials and products that can be used in diverse economic sectors.

¹¹⁵ The European Innovation Partnership on Raw Materials: Raw Material Scoreboard 2018.

Figure 11 Food waste valorisation pathways

Source: Cristobal J. et al. (2018)

Stakeholder opinion

89% of the 206 respondents to the Open Public Consultation stated that it is either relevant or very relevant to maximise the valorisation of organic waste, agriculture and forestry residues. There were no notable differences of views on this point between different respondents categories.

2.1.3. Sustainability deficit of EU industrial production processes (Sustainability deficit)

As explained, the bio-based industrial systems have the potential to improve the environmental performance of industrial production. An example is the production of polyactic acid (PLA), a bio-based thermoplastic polyester that can replace polyethylene or polystyrene in many applications including packaging. The life cycle environmental performance of PLA can be significantly better than polystyrene¹²⁰, HDPE or PET (see Figure 12).

¹²⁰ Vera I. et al. (2020) A carbon footprint assessment of multi- output biorefineries with international biomass supply: a case study for the Netherlands, Biofuels, Bioproducts, and Biorefining vol. 14(2)

Figure 12: Climate efficiency of bio-based and fossil based plastics

Source: Ronzon T. et al. (2017): Bioeconomy report 2016. JRC Scientific and Policy Report.

This improved environmental performance is mainly due to the intrinsic carbon efficiency of bio-based materials and due to the potential to utilise abundant biological waste, thus reducing the pressure on ecosystems. Many bio-based processes and products are also less polluting or less toxic. However, the overall environmental performance of bio-based systems depends on many factors, including the environmental performance of associated activities upstream and downstream. In this respect, the environmental impact of primary biomass production may have the dominant effect on the overall performance of the whole production system. For example, if the biomass is produced in an intensive agriculture system with high energy and chemical input, and/or biomass must be transported to distant processing facilities, the overall life-cycle negative impact can be significant. Bio-based industrial activity can also be seen as causing biodiversity loss and ecosystem degradation if too much biomass is extracted from valuable natural ecosystems or when excessive biomass demands lead to land use change and conversion of natural area into low biodiversity agricultural land. For bio-based production systems to be sustainable, they have to be designed and implemented with this objective in mind and their performance has to be assessed from a whole life-cycle perspective. This is not always the case, and a number of real life applications have dubious environmental performance.

For instance, in the past, the bio-fuel segment of the bio-based industry faced the criticism that the overall environmental impact of bio-fuel production can be negative due to energy intensive production of biomass used in the first generation bio-fuel refineries, long transport routes and indirect carbon emissions from land use change. As a consequence, sustainability conditions have been set for this sector at EU level¹²¹ in 2018. A number of older bio-fuel refineries fail to meet these sustainability criteria¹²² and therefore need to upgrade. All new biofuel facilities have to meet the strict conditions concerning their overall carbon efficiency, e.g. 65% greenhouse gas savings by 2021.

In contrast to the above example, the rest of the bio-based industry operates in an incomplete regulatory environment. Industrial facilities have to comply with the applicable environmental legislation such as the Industrial Emissions Directive¹²³ or the regulation

¹²¹ Renewable Energy Directive 2018/2001/EU

¹²² Vera I. (2019): A carbon footprint assessment of multi-output biorefineries with international biomass supply

¹²³ Directive 2010/75/EU

concerning the use of GMOs¹²⁴ but the issue of sourcing of biomass, potential indirect land use change and biodiversity impact, and the overall carbon efficiency of bio-based systems are not regulated. In the absence of a comprehensive regulatory system, the environmental performance is thus a matter of voluntary commitments in the context of corporate social responsibility. The weakness of voluntary commitments is further exacerbated by the absence of robust methodologies to assess certain environmental impacts and generally accepted sustainability criteria. Uncertainties about the environmental performance of commercial bio-based installations, materials and products deter investors and undermine the public trust in bio-based solutions.

Stakeholder opinion

The majority of the respondents to the Open Public Consultation across all stakeholder groups (industry, academic and research institutions, public authorities and NGOs etc.) considered the proposed initiative Circular Bio-based Europe to be either very relevant (76%) or relevant (14%) for reducing greenhouse emissions. No respondents from different stakeholder groups stated that this target was ‘Not relevant at all’.

2.2. What are the problem drivers?

2.2.1. Innovation deficit drivers

The innovation deficit of the bio-based European industry is underpinned by three drivers:

(a) *Lack of R&I activities across scientific disciplines and along the research-innovation chain*

This is linked to the lack of collaboration between scientific disciplines with the objective to develop bio-based materials and product innovation. The intensity of cross-fertilisation between relevant scientific developments tends to be lower for bio-based materials than for health and nutrition applications.¹²⁵ Moreover there is less experimenting, testing and demonstrating of bio-based innovative technologies than in other biotech sectors, therefore it takes longer time for the material innovation to reach the market. The bio-based materials and products research competes for talents with sectors that provide more opportunities for revolutionary breakthrough, scientific prestige and profitability. As a result, in recent years there was an insufficient number of radical innovations in bio-based materials and products, compared to what would have been possible thanks to advances in basic research in life sciences or IT (e.g. artificial intelligence). In addition, increase in new products or value chains resulting from cross-disciplinary research remained limited.

Stakeholder opinion

With regard to the uptake in innovation problems, about 64% of the respondents to the OPC (industry, academic and research institutions, public authorities and NGOs etc.) have indicated that the research and innovation efforts at EU level address the issue of lack of competitiveness with traditional products/materials.

(b) *Underdeveloped and insufficiently integrated R&I capacity across the EU to support sustainable bio-based systems*

¹²⁴ E.g. Directive 2009/41/EC on contained use of genetically modified microorganisms and Regulation (EC) 1946/2003 on transboundary movement of GMOs.

¹²⁵ McKinsey (2020): The Bio Revolution.

There is an underdeveloped capacity for R&I in bio-based systems in some parts of the EU, in particular the Eastern and Southern European regions. The research efforts in bio-based material and products R&I are concentrated in Belgium, the Netherlands, Nordic countries and some regions of Germany, France, Italy and Spain. In other regions, the capacity for R&I has not been sufficiently developed, even though there would be great regional/local potential for bio-based industry due to availability of biomass, or presence of human skills. This missing capacity results in less intensive research and innovation development and commercialisation in those regions.

(c) Lack of R&I activities on sustainability issues

In parallel, there is an insufficient focus of R&I activities on sustainability issues. Due to limited regulatory pressure, R&I on sustainability aspects has not been of the highest priority, especially for corporate R&I. For example, the technological challenge to efficiently process non-homogenous mixtures of biological waste, such as municipal waste, remains untackled. Insufficient scientific effort has been devoted to studying the environmental impact of the bio-based industry; and as result there is still no full understanding of all impacts and their scale. Methods and tools for assessing this impact, including the life-cycle assessment (LCA), LCA databases and sectoral specifications, have not yet been developed at a level comparable to those for other industrial sectors. Consequently, there is insufficient scientific guidance for decision-makers on how to set sustainability conditions for bio-based industry operations in real life.

2.2.2. Market uptake deficit drivers

The market uptake deficit is caused by the following three drivers:

(d) Limited understanding of the potential of bio-based R&I solutions by industry and policy stakeholders

There is an information asymmetry between scientific actors who understand the potential of scientific advances in the bio-based systems without a full grasp of business models and the market situation, as opposed to market and policy actors who are not fully aware of the fast development in science and innovation and may thus not entirely understand the opportunities created by scientific inventions.

For companies that did not develop sufficient R&I capacity, especially for SMEs, it takes a longer time to integrate new bio-based technology in their business strategy and models. As a result, companies are not sufficiently engaged in experimentation and demonstration activities that are critical for maturing of technology or miss the opportunity to become part of emerging value chains and markets.

For policy makers at EU, national and local level, especially in less economically developed Member States and regions, it is still difficult to assess the potential of the bio-based industry and integrate it in national and regional development strategies. Indeed, there are a number of countries that have not yet developed their national bioeconomy strategies and only a limited number of regions have developed such strategies at their level. The barriers to market uptake of bio-based solutions are not well understood by policy makers and consequently policies do not necessary create favourable conditions, e.g. through incentives. Existing EU instruments such as the Common Agriculture Policy or the European Regional Development Fund are not adequately deployed in support of bio-based industries in many Member States.

(e) *Uneven playing field for bio-based materials and products*

There is an uneven playing field for conventional and bio-based industries in markets where bio-based materials compete with conventional materials, e.g. bio-based plastics versus plastics made from fossil raw material. Markets with conventional products tend to be consolidated with established supply chains and business relations. Companies may be locked-in into technologies and capital investment that has not yet been repaid. This results in inertia and slow adoption of bio-based solutions if the economic premium is not high enough. This in turn prevents economies of scale from taking effect. A special case of uneven playing field occurs when bio-based products compete with conventional products whose price is distorted by economic incentives or where price does not integrate negative externalities (e.g. CO₂ emissions, or impact on biodiversity), especially if markets do not reward positive externalities of bio-based products (e.g. no price premium for carbon efficiency). The latter problem occurs for instance in the competition between bio-based and petrochemical-based products, where the economic viability of bio-based product depends on the price of oil. Without active governmental policies to address this market failure, some beneficial bio-based solutions will not be economically viable in the foreseeable future.

Stakeholder opinion

178 respondents believe that there is a lack of competitiveness, when compared to traditional products and materials.

The uneven playing field is an important driver of the market uptake deficit, however this R&I initiative is not able to address it. This driver is provided as contextual information in the impact assessment, for the sake of completeness and to highlight relevant elements that can impact the proposed initiative.

(f) *Perceived investment risk*

Perceived investment risk reduces access to finance possibilities for bio-based projects, particularly with regard to necessary capital expenditure¹²⁶. Investors perceive the bio-based industry as excessively risky due to technological, market¹²⁷ and policy uncertainties. Indeed, novel technologies have not yet proven on the market that they can deliver the expected economic performance. Additional market uncertainties are related to e.g. the instability in supply of biomass, or its price volatility¹²⁸, consumer demand, but also to the market failures described above. The policy uncertainty often stems from the fact that the bio-based industry is young and dynamic and it is thus not clear whether it will be subjected to environmental or other regulations and what policies and incentives affecting its economic performance will be developed in the future. The shift in public perception of bio-based solutions both in a positive and negative direction can further increase the uncertainty levels.

¹²⁶ Commission Expert Group on Bio-based Products - Final Report, Commission Expert Group, 2017 https://ec.europa.eu/growth/content/commission-expert-group-bio-based-products-calls-alignment-bioeconomy-strategy-eu-policy_en

¹²⁷ Innovation Ecosystems in the Bio-economy, OECD, 2019, <https://www.oecd-ilibrary.org/docserver/e2e3d8a1-en.pdf?expires=1594641236&id=id&accname=oid031827&checksum=C630B83C3B49E92A37A01241DE4D9C8D>

¹²⁸ EIB (2017): Access to finance conditions for Investments in Bio-Based Industries and the Blue Economy

As a result, many bio-based projects are not yet considered bankable. In the general absence of venture capital for technological innovation in Europe, these projects will only be financed if there is an active public policy on de-risking the bio-based investment¹²⁹.

Stakeholder opinion

A high number of stakeholders who responded to the public consultation believe that there is a lack of public (162) and private (133) investments in the bio-based industry.

Another consultation targeting the bio-based industry stakeholders was carried out by the European Investment Bank in the context of the study on Access to Finance in the European Bio-based Sector¹³⁰. In this consultation 79% of respondents indicate that the limited interest from private financial market participants is related to the lack of understanding of the specificities bio-based industries.

2.2.3. Environmental deficit drivers

The overall environmental performance of the bio-based industry will depend on its performance in the three key unregulated environmental aspects: (1) sourcing of feedstock including biowaste, side streams and residues, (2) indirect land use changes and (3) overall carbon efficiency of bio-based industrial systems. The prospect of future environmental regulation targeting these aspects is questionable – the bio-based industry is so wide and varied in terms of biomass sources, technologies and products that it may not be possible to effectively regulate the entire scope of bio-based activities in the same way as it is possible to regulate the environmental performance of just one particular bio-based value chain of biofuels. In the continuous absence of specific regulation, the environmental deficit problem can be linked to the following driver:

(g) Lack of environmental considerations in the development and implementation of R&I bio-based projects

This driver stems from the lack of a commonly accepted regulatory basis for environmental considerations due to the absence of established assessment methodologies and of broadly accepted sustainability criteria¹³¹. This severely limits the ability to integrate sustainability aspects in decision-making by concerned industries and public authorities.

However, even if such criteria are developed, sustainability considerations may still be missing in the development and implementation of bio-based projects at different TRLs, notably from early innovation to demonstrations until market application.

Due to the absence of active promotion and implementation of sustainability criteria through regulation, voluntary industry commitments, ‘soft’ policy such as strategies, recommendations and industry standards, or through public pressure, there is a real risk that a number of bio-based projects will be implemented and at a later stage identified as having a poor environmental record. This might result in damage to the reputation of the bio-based industry as a contributor to societal objectives and undermine the public trust in bio-based

¹²⁹ EIB (2017): Access-to-finance conditions for Investments in Bio-Based Industries and the Blue Economy

¹³⁰ EIB (2017): Access-to-finance conditions for Investments in Bio-Based Industries and the Blue Economy

¹³¹ Note that while problem driver 3 (g) also refers to the absence of methodologies/criteria like problem driver 1 (c), these two issues are different. Under problem 1 (c), the relevant driver is about a lack of R&I on environmental impacts of bio-based solutions. Here instead, the driver concerns the absence of a commonly accepted regulatory basis for environmental considerations and decision-making by concerned industries or public authorities; The two are indirectly connected in the sense that addressing driver 1 (c) allows to develop the necessary building blocks to facilitate the solutions of driver 3 (g).

materials, even if the majority of initiatives have a positive contribution. The BBI JU did not have the appropriate governance structure to assess these type of results.

2.3. How will the problem evolve?

The global population and economy are projected to continue growing over the coming decades. This will drive material consumption including demand for bio-based materials and products globally. The demand for bio-based products will increase also in the EU economy.

At the same time, the Commission's aim to reduce the European ecological footprint and to reach the ambitious policy objectives of climate neutrality by 2050, will require the replacement of many of the fossil-based products with bio-based ones. The need for bio-based innovation that will increase economic efficiency of production and address environmental issues will grow.

In the absence of effective measures to address the problems described above, the underlying drivers will continue to affect negatively the development of a circular bio-based industry. R&I will continue to take place as a result of public and private funding, and innovative solutions will reach the market, albeit at a slower pace than is desirable to meet the EU's climate and environmental objectives for the coming decades. The actual societal benefits will fall short of the potential benefits both in terms of economic and environmental performance.

For example, the annual economic benefit expected in 2030 from the global material bio-based innovations in the current innovation pipeline is estimated to 400 million trillion USD¹³². This 'business as usual scenario' represents only a modest increment in the economic value compared to the actual size and potential of the EU bio-based industry.

In terms of environmental performance, many bio-based industrial activities will bring environmental benefits because of their intrinsic environmental performance. However, and as indicated above, there may also be bio-based projects that do not take environmental considerations into account in their design and implementation, thus leading to possible negative impacts on ecosystems or a limited ability to contribute to climate neutrality objectives.

In general, the current situation of not reaping all the potential benefits of bio-based innovation will continue. These forgone societal benefits are the main negative impact of not acting in this area.

3 WHY SHOULD THE EU ACT?

3.1 Subsidiarity: Necessity of EU action

To further develop the bio-based economy, neither single stakeholders nor individual Member States will be able to reach the required critical mass on their own, thus showing the clear necessity of tackling these ambitions on an EU scale. A multi-sectoral approach is needed to combine the strengths of industries, primary producers across regions and EU countries, enabling a sustainable transition from a fossil-based to a sustainable and circular bio-based economy. There is a need to mobilise the actors of the bio-based value chains and

¹³² McKinsey (2020) The Bio Revolution.

to build on the structuring effects already observed in the BBI JU partnership. Actors and stakeholders throughout all segments of the value chain (primary production and waste streams, processing and end applications) are engaged in shaping business models and industrial cooperation which did not exist before, providing evidence of a structuring effect and systemic change in the bio-based industry. To date and through the implementation of the BBI JU, 113 new bio-based value chains were created, many of those involving several sectors and transcending national borders.¹³³

An innovative value chain is created when its resulting (new) product or service has been tested and validated, and is ready for a specified and accepted market application. To exist, these new value chains need to be economically viable and to fulfil all relevant sustainability criteria. Each of the value chains has business cases or commercialisation plans.

These new bio-based value chains can thus result from innovative cooperation between several often atypical economic actors, which combine feedstock with innovative or traditional technologies and produce new bio-based products or market applications. They have the potential to be replicated across Europe and beyond, and support the development and competitiveness of the European bio-based market and the creation of new bio-based products.¹³⁴

Such links are clear in the case of the highly forested countries and highly productive agricultural regions, where biomass producers need to be connected to industrial centres in Europe in order to generate new value through the development of integrated sustainable value chains. Another case are those local authorities that require links with industries and support by regions to solve their waste problems in a sustainable way that can also deliver economic added value. It remains very difficult to build and consolidate those links by acting only at the national or local level. Indeed, the need for EU-level intervention in this area was supported by a large majority of respondents to the online public consultation on the proposed CBE initiative.

Moreover, flagship and first-of-its-kind biorefinery plants require costly demonstration. Implementing innovation activities at high Technology Readiness Levels (TRL 6 to 8) requires a strong degree of involvement from all players of the value chain – from primary producers to industry and brand owners. This level of engagement is usually not achievable under standard collaborative research, but only via a partnership as shown by BBI JU. This is why the European Green Deal and the updated Bioeconomy Strategy have indicated the need for a partnership in the bio-based industry.

3.2 Subsidiarity: Added value of EU action

Another rationale for EU-level intervention in this area is that most of the barriers and long-term challenges to further develop the bio-based industry are not adequately addressed at national level but rest firmly upon EU-level regulation. Examples range from sustainable biomass supply to market pull via targets, product standardisation and green public procurement schemes.

A clear EU added value of the proposed CBE initiative lies in its key enabling role for implementing the European Commission's updated Bioeconomy Strategy and Action Plan.

¹³³ BBI JU, Annual Activity Report 2018

¹³⁴ *ibid*

A coherent EU-wide approach is also necessary to ensure that the right balance is found between growth (European industrial competitiveness) and sustainability (social and environmental) objectives.¹³⁵

Tackling these challenges at European level between industry and the EU would allow:

- Carrying out the research and innovation needed, and that no single company, public research institution or Member State can perform alone precisely because only a combined research capacity can deliver the necessary joint efforts for achieving shared market and European Research Area objectives;
- Tackling the absence of an agreed long-term budget plan and strategic technical and market objectives to encourage industry and the research community to commit more of their own resources. This is needed to reach critical mass, which cannot be achieved by acting at the national level alone, given the ambition of the identified policy objectives and aspirations;
- Promote an optimal coherence of research and innovation efforts between industry and public actors, thereby avoiding gaps, overlaps and fragmentation of research and innovation coverage, when industry and publicly-funded research do not align their funding and agendas;
- Bringing the green transition to the attention of industry and raising the sustainability bar and corporate responsibility via integrated and continuous programmes covering fundamental research, applied research and EU-level demonstration and flagship activities;
- Addressing the need to strengthen the innovation spirit and cooperation for market development between value chains operating across different countries and sectors. This fosters the exchange and pooling of knowledge and experience, and facilitates the involvement of all market actors, in particular the SMEs.

Stakeholder opinion

87% of respondents to the OPC (including industry, academic and research institutions, public authorities and NGOs) mentioned as “very relevant” the involvement of industry in setting joint long-term agendas to ensure that the proposed European Partnership would meet its objectives. A large part of respondents also indicated that the involvement of academia (47%) and Member States and Associated Countries (44%) is ‘very relevant’. The answers are more evenly split with regard to Foundations and NGOs (25%) and other stakeholders (27%).

4 OBJECTIVES: WHAT IS TO BE ACHIEVED?

4.1 General objectives of the initiative

Based on the identified problems, the initiative’s main objective would be to contribute to accelerating the development and growth of those segments of the bio-based industry that deliver climate and environmentally efficient and innovative solutions to meet the material needs of the society, while ensuring a sustainable, fair and just economic growth. This acceleration would make the bio-based industry play the role that recent EU policies assigned to it and deliver significant contributions towards climate neutrality, resource

¹³⁵ Philippidis G. et al. (2018) Sailing into Uncharted Waters: Plotting a Course for EU Bio-Based Sectors, *Ecological Economics* 147

efficiency and zero pollution by 2030. To achieve this overarching goal, general and specific objectives are set for the three problem areas described in section 2, namely:

- To **accelerate the innovation process and development of bio-based innovative solutions**. This does not only imply more intensive basic research in biotechnology and other related scientific and technological disciplines but also accelerating the maturing process to bring innovative solutions to the market through more intensive efforts in experimentation, testing, demonstration and deployment.
- To **accelerate market deployment of the existing mature bio-based innovative solutions**. This implies supporting a more intensive process that goes from demonstration and first market applications to replication, mainstreaming and scaling up of bio-based industrial activities across Europe, especially in regions that have an autochthonous potential for it (e.g. regions with high production of biomass and biological waste), to achieve the significant positive economic and environmental impact associated with these solutions.
- To **ensure a high level of environmental performance of bio-based industrial systems** so that their market deployment contributes to the achievement of EU Green Deal objectives. The focus will be on carbon emissions, circularity and ecosystem protection, i.e. the impact areas where the bio-based industry is currently not regulated. This implies the development of scientifically robust metrics and performance benchmarks to inform future policy and business choices, as well as promoting the consideration of sustainability aspects throughout the whole innovation chain (from basic research, to development of innovative solutions, to market deployment) and across the entire bio-based value chains (from biomass sourcing to industrial processing, production and consumption).

4.2 Specific objectives of the initiative

In order to achieve these general objectives, five specific objectives are defined. These specific objectives respond to each of the problem drivers discussed in Section 2.2:

(a) to **reap the benefits of the advancement in life sciences and in other scientific disciplines for the development and demonstration of sustainable bio-based solutions** by increasing the intensity of cross-disciplinary research and innovation activities. This acceleration and cross-fertilisation is expected to take place along the whole innovation chain, from basic research to experimentation, demonstration and to first market applications.

(b) to **increase and integrate the R&I capacity of stakeholders across the European Union** that will help to exploit the local bioeconomy potential. The focus will be on the regions that are currently lagging behind the leading Member States and the regions with the greatest bioeconomy gaps. The targeted impact is a more balanced distribution of benefits from bio-based innovation across Member States and regions.

(c) to increase the R&I capacity for **addressing environmental challenges and development of more sustainable bio-based innovations**. This implies the need to intensify R&I activities on the sustainability aspects of bio-based industries to ensure that sustainability issues are considered throughout the whole innovation chain and environmental performance are integrated in future innovative solutions. This sustainability aspect includes also the source of biomass and the development of technologies that can efficiently utilise all sorts of biological waste.

(d) to **reinforce the integration of bio-based R&I processes in EU industrial value chains** by increasing awareness among industry and other R&I stakeholders of the advances in bio-based solutions and mobilising them to develop strategies for applying bio-based solutions as well as specific projects. Engage industry and other R&I actors to participate in innovation development, in particular in the testing, demonstration and replication phases.

(e) To **reduce the risk for R&I investment in bio-based companies and projects** by providing directionality for EU R&I investments in bio-based industries; addressing technological, market and policy barriers,¹³⁶ and supporting the development of a level playing field for bio-based materials replacing conventional materials.

Stakeholder opinion

Respondents (1783) to the Open Public Consultation across all stakeholder groups (industry, academic and research institutions, public authorities and NGOs etc.) indicated that deployment and piloting activities are very relevant (72%) or relevant (20%) to ensure that the proposed initiative would meet its objectives. No respondents from different stakeholder groups indicated that these activities were 'Not relevant at all'.

(f) to **ensure that environmental considerations are taken into account in the development and implementation of R&I bio-based projects**, by setting operational sustainability criteria for bio-based industrial systems to support decision making in R&I, market deployment and policy. Sustainability criteria should include robust science-based indicators and benchmarks corresponding to the ambition of the EU Green Deal policies. They should be applicable at sector, value chain, industrial installation and product level and should be based on the life-cycle approach. The application of sustainable criteria should be promoted across the bio-based industry.

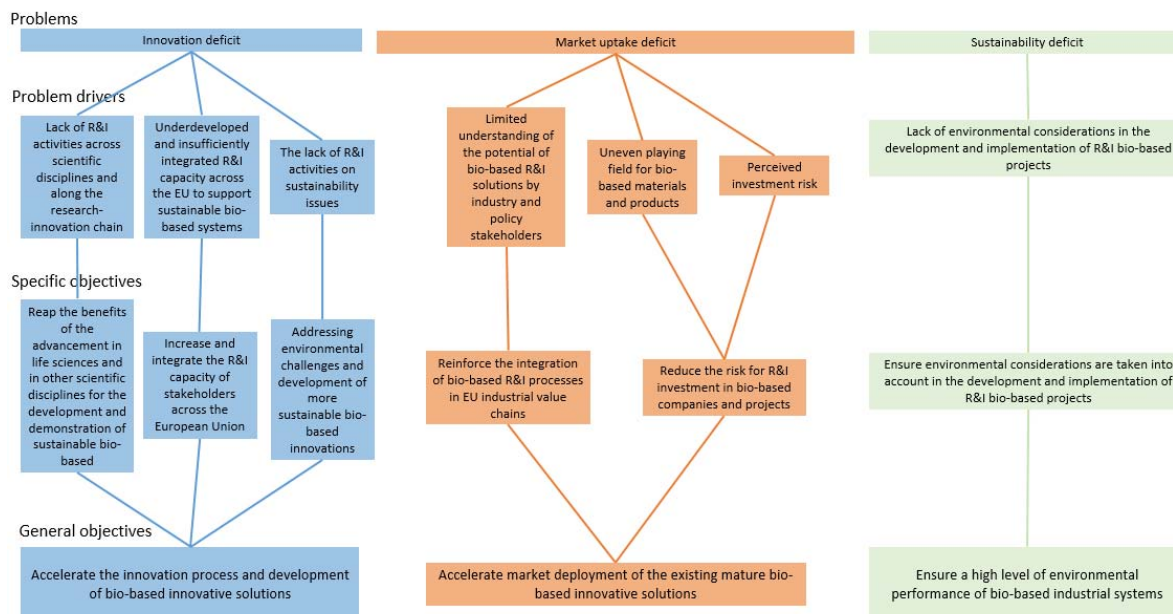

The choice of the proper implementation form is fundamental for these objectives to be achieved. Indeed, lessons from previous experience have shown that the mode of implementation and in particular the governance structure and requirements on the private partners are central for the initiative to stay on the desired track.

4.3 Intervention logic of the initiative

The relationship between the general and specific objectives of the potential initiative for a Circular bio-based Europe is shown in the Figure below. The impact pathways are shown in Annex 6, Figures 1 to 3.

¹³⁶ This refers to policy barriers that can be addressed by the initiative. They include the lack of long term strategic support by public authorities to the development of bio-based industry, e.g. through national and regional bioeconomy strategies.

Figure 13: Intervention logic for the initiative on Circular Bio-based Economy

How would success look like?

Should the initiative deliver on its specific objectives, it is expected that it would have the following impacts:

Scientific impacts

- Accelerated development of bio-based innovations that would deliver environmental and productivity improvements through new bio-based production processes and products based on EU resources;
- Reinforced scientific and innovation capacity that is necessary for exploitation of the EU potential for bio-based industrial production, including in the regions where currently this capacity is underdeveloped;
- Increased R&I capacity for addressing the key sustainability challenges and trade-offs in the bio-based industry, particularly as regards the carbon neutrality and circular economy transitions.

As a consequence, the EU would maintain its current leadership in bio-based systems and achieve strategic autonomy in an industry that is critical for the long-term sustainability of EU economy.

Economic/technological impacts

- A number of bio-based innovations demonstrating the economic and environmental potential of specific bio-based solutions would reach the stage of first market application and bring tangible economic and environmental benefits;
- A structured process for collaboration R&I between R&I actors, industry (including SMEs) and other bio-based innovation stakeholders that would facilitate deployment of bio-based innovation;
- Reduced investment risk and improved access to finance for bio-based industrial projects.

In general terms, the initiative would increase the capacity to deploy bio-based innovation that valorises domestic biomass, which would lead to higher growth, competitiveness and resilience of the EU economy.

Environmental/Societal impacts

- Enhanced circularity and environmental sustainability of the European bio-based industries;
- Better integration of primary biomass producers in bio-based value chains to contribute to rural development.

As a consequence, the initiative would make the EU economy and society increasingly circular and environmentally sustainable, and would contribute in particular to the EU climate mitigation objective. In terms of social impact, if successful, the proposed initiative will stimulate the involvement of primary biomass producers and waste and side-stream providers in the bio-based industry, which in turn will increase their revenues and revitalise rural and coastal regions as well as municipalities and urban areas.

With efforts maintained over time, all impacts are expected to materialise within the time framework foreseen for the proposed initiative. The choice of the proper implementation form is fundamental for the general and specific objectives to be achieved. Lessons from previous experience, specifically from the BBI JU have shown that the mode of implementation and in particular the governance structure and requirements on the private partners are central for the initiative to deliver on the targets set out in the intervention logic.

4.4 What is needed to achieve these objectives – Key Functionalities needed

Given the focus of the impact assessment on comparing different forms of implementation, the identification of “key functionalities needed” allows making the transition between the definition of the objectives and what would be crucial to achieve them *in terms of implementation*. These functionalities relate to the type and composition of actors that have to be involved, the type of range of activities that should be performed, the degree of directionality needed and the linkages needed with the external environment.

4.4.1 Type and composition of the actors involved

For the initiative to achieve its objectives, there is a need to foster collaboration, contribution, co-design and co-creation involving a wide set of actors and stakeholders across scientific disciplines, industrial sectors, value chains and territories. It is important to ensure openness towards different actors and stakeholders, and guarantee their involvement in defining needs and priorities, in setting innovation and research agendas, as well as in innovation activities. However, each actor and stakeholder group may have different interests¹³⁷. This requires that the proposed initiative be able to identify joint interests, define objectives and priorities that all stakeholders can support, and ensure an adequate balance of input and benefits for stakeholders involved in the initiative. In particular, it is important that all stakeholders actively support the public interest objectives of the initiative,

¹³⁷ BIOVOICES project (Connecting Biobased Forces for a Sustainable World), *Synthesis of market perspectives to develop bio-based value chains*, 2018.

and specifically those related to the sustainability of the bio-based industry. One of the underlying issue of the previous BBI initiative was that certain stakeholders were not as involved as desirable at all stages of implementation, even though SME participation was very prominent in the BBI JU.

Stakeholder opinion

86% of respondents to the open public consultation (industry, academic and research institutions, public authorities and NGOs) see “a broad group” and 75% “flexibility in composition” as very relevant or relevant for the success of the proposed initiative.

It is therefore foreseen to involve the following stakeholders in the proposed initiative:

Industries: the bio-based industry operates as a broader industrial system that includes biomass producers as upstream actors, the bio-refining segment as the core segment that converts biomass into industrial materials and products, and the downstream segment that processes the bio-based materials into final products (Figure 14). Ancillary actors may include providers of technology and necessary inputs such as energy, as well as services such as transport, consultancy, etc. All segments are very wide, as there are many types of biomass, refining processes, and bio-based materials and products, resulting in thousands of bio-based value chains that are increasingly cross-sectoral. The three segments included in the Figure 14 face different R&I challenges related to their specific function but they all recognise the central role of biomass refining to enable business operations upstream and downstream. All segments are interested in the development of complete bio-based value chains enabled by biorefining technologies.

Figure 14 Basic composition of the bio-based industry

Stakeholder opinion

The open public consultation shows that 97% of 205 respondents (industry, academic and research institutions, public authorities and NGOs etc.) see industry as very relevant or relevant for CBE.

Smaller economic actors, such as farmers and SMEs, have been identified as important players in the bio-based value chains. Their active involvement in the bio-based economy in general contributes to local economic development, job creation, and more dynamism in the regions¹³⁸. In the BBI JU, SMEs have already increased their participation in projects (40% SME participation¹³⁹ as compared the Horizon 2020 average and 20% target), but there still is a vast room for further outreach and mobilisation of SMEs especially in the rural, coastal and less advanced regions. Many primary biomass suppliers are SMEs and they have

¹³⁸ BBI JU, *The BBI JU SME landscape: Driving impact and innovation*, Brussels, 2019.

¹³⁹ Analysis by BBI JU.

already been identified as a special group that needs to play a bigger and more specific role in the bioeconomy and bio-based value chains.

Research organisations¹⁴⁰ have been actively contributing to the whole research spectrum from basic research to pilot plants and commercialisation in the BBI JU, by bringing knowledge capital and research facilities as resources to create new bio-based solutions. The input from scientific partners is needed to generate the most innovative solutions (¹⁴¹). The interest of research organisations in the proposed initiative is to obtain scientific credit and reputation from quality R&I results as well as funding for their research activities.

Stakeholder opinion

The open public consultation shows that 73% of respondents (industry, academic and research institutions, public authorities and NGOs etc.) see research organisations as very relevant or relevant for CBE.

Public bodies from Member States, regions and municipalities can safeguard the public interest and direct the initiative towards societal objectives. They can also promote and create favourable conditions for the development of bio-based industries. This includes the alignment of European, national and local level strategies and providing co-funding from national, regional and local funds. Regional authorities may play a key regulatory role as bio-based activities may require permits issued at the regional level. This important role of public authorities implies that their function is appropriate in the initiative's governance.

Stakeholder opinion

The open public consultation shows that 75% of respondents (industry, academic and research institutions, public authorities and NGOs) see public authorities as very relevant or relevant for CBE.

Civil society organisations such as consumer organisations or non-governmental environmental organisations can actively contribute to the initiative by ensuring the balance of environmental, social and economic objectives in its agenda, and can also raise the visibility and public awareness of the challenges and solutions emerging under the proposed initiative. The role of civil society organisations in balancing interests in a public-private partnership setup seems not to be fully recognised by stakeholders yet.

Stakeholder opinion

The open public consultation shows that 50% of respondents (industry, academic and research institutions, public authorities and NGOs) see civil society organisations as very relevant or relevant for CBE.

4.4.2 Type and range of activities needed

The activities needed for the initiative to succeed and address the R&I deficit described in Section 2 and accelerate the development and maturing of innovation in the bio-based industry, include:

- **public and private R&I activities** that are programmed to ensure the desired directionality to R&I in bio-based innovation;

¹⁴⁰ The open public consultation shows that around 73% of respondents see them as “very relevant” or “relevant” for CBE.

¹⁴¹ European Commission, *Interim Evaluation of the Bio-based Industries Joint Undertaking (2014-2016)*, Brussels, 2017.

- a **mobilisation of public and private funding** of R&I activities to increase the overall financial support to the sector;
- multidisciplinary projects to **reach and mobilise R&I actors from different scientific disciplines**;
- intensified **R&I activities** along the whole innovation chain **from low to high TRLs**;
- reaching and **mobilising R&I actors in regions** where the intensity of R&I in the bio-based systems is inadequate compared to the local potential for bio-based industrial activities in that region.
- R&I activities focussed on issues of public interest. For the proposed initiative, this refers to the **environmental performance of the bio-based industry** – both in the terms of understanding the relevant problems and developing solutions to them.

To address the market uptake deficit by accelerating the deployment of innovation in the bio-based industry, the following are needed:

- initiate communication and collaboration between R&I and industrial stakeholders to raise awareness of rapidly evolving knowledge and technology, and facilitate collaboration between industry actors to develop market solutions based on bio-based innovation such as new bio-based products, value chains and business models;
- **reach** other actors and stakeholders such as **national and regional authorities** that are able to create more favourable conditions **for market uptake**, e.g. through bioeconomy strategies and different forms of incentives;
- **de-risk private investment** by using public funds to co-finance close to market projects.

Finally, to address the sustainability deficit and ensure the environmental performance of the bio-based industry, the following are needed:

- **set scientifically robust sustainability criteria and performance benchmarks**, and apply them in all publicly funded R&I activities in the bio-based industry and to all projects supported by the initiative, and
- promote these criteria beyond the initiative, by agreeing with the private partners that **these criteria will become de facto industrial standards to be observed by the industry** on voluntary basis.

4.4.3 Priority setting system and level of directionality required

A strategic vision for the proposed Circular bio-based Europe initiative (including its priorities and directionality) that is shared by all shareholders is essential for maximising the positive impact of the initiative. This strategic vision should safeguard public interests, balance the activities towards different general and specific objectives, and reconcile the different priorities of a diverse group of bio-based stakeholders. The focus should be on synergistic solutions that would reconcile potentially conflicting objectives and interests towards an effective contribution to the Green Deal and the Next Generation EU policy objectives.

This shared strategic vision would be defined in the Strategic Innovation and Research Agenda (SIRA) and annual Work Programme documents. These documents would be subject to extensive consultation involving all relevant stakeholders. Decision should be taken within a governance system that ensures balanced representation of the industry and its segments and gives an appropriate role to other stakeholders. In this governance system, the Commission should have the role of the ultimate guardian of the public interest and the

coherence of the initiative with EU policies. This also implies adequate financial contribution of private partners to the initiative.

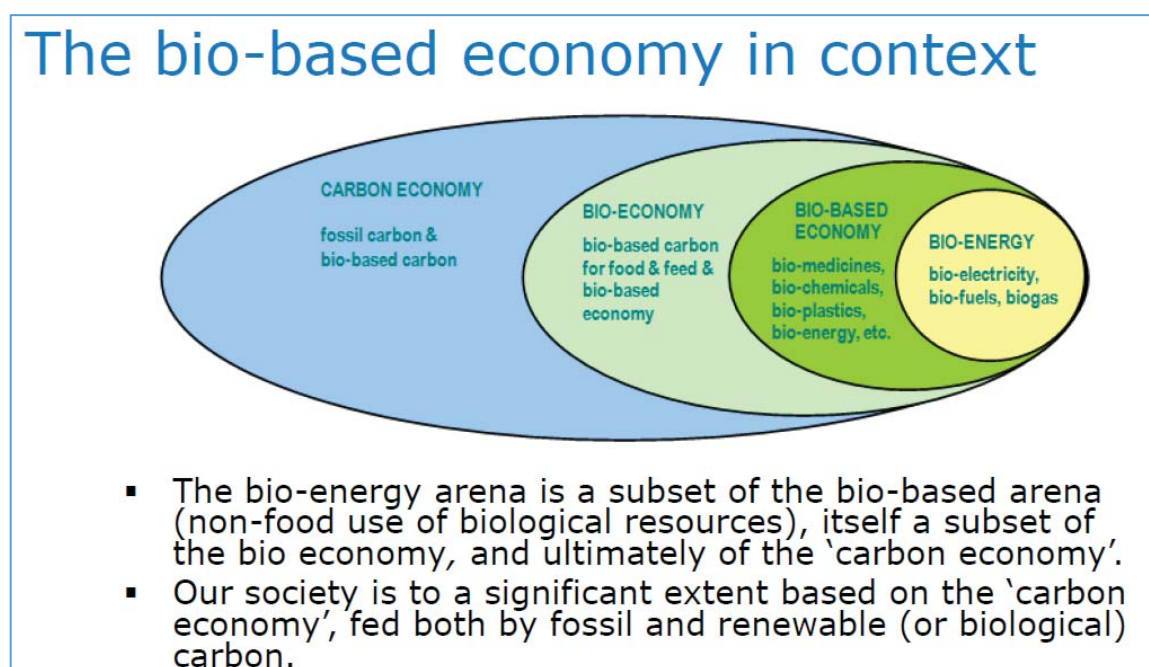

Stakeholder opinion

The open public consultation shows that 66% of 202 respondents (industry, academic and research institutions, public authorities and NGOs etc.) considers securing private investment in bio-based innovation as very relevant or relevant for CBE.

4.4.4 Coherence needed with the external environment

An initiative for a Circular bio-based Europe would need to be firmly anchored to the European Green Deal, the EU Bioeconomy Strategy, the new Circular Economy Action Plan, the new Industrial Strategy, the Farm to Fork Strategy and the Sustainable Development Goals. Figure 15 shows how the bio-based economy is fitting within the larger context of the bioeconomy.

Figure 15: The bio-based economy in context

After: Kwant K.W., *Biobased Economy in the Netherlands and the regions – Opportunities & Challenges*, Netherlands Enterprise Agency, 2017 (after: van Beeck, N. et al., *An innovative perspective: Transition towards a bio-based economy*, in: *Sustainable Energy Solutions in Agriculture*, ed. J. Bundschuh and G. Chen, London, 2014).

Inter alia, the initiative would need to seek synergies in terms of funding projects as well as in terms of programme development with the following programmes and the initiatives mentioned below, while avoiding overlaps. In particular, strong complementarities are expected with Cluster 6 of Horizon Europe as well as with all other initiatives in the same area. It is important to highlight that the proposed CBE initiative's centre of gravity lies with bio-based industry actors and value chains.

- At the EU level¹⁴²: Horizon Europe (mainly Pillar II, Cluster 6), the InvestEU instrument, the European Regional Development Fund (ERDF), the European

¹⁴² The open public consultation shows that 75% of the respondents see this as very relevant or relevant for CBE.

Agricultural Fund for Rural Development (EAFRD), the LIFE programme, EU's Common Agricultural Policy (CAP), the European Maritime and Fisheries Fund (EMFF), the Agricultural European Innovation Partnership (EIP-Agri), the European Circular Bioeconomy Fund (ECBF), the BIOEAST initiative¹⁴³, and the EU Protein Strategy. Blending approaches promoted by InvestEU¹⁴⁴ could combine e.g. loans for infrastructure with CBE research grants to develop especially large scale biorefineries, where infrastructure needs could be financed with sources other than supporting programmes such as CBE. Joint transdisciplinary projects (¹⁴⁵) with other partnerships¹⁴⁶, e.g. CCNI (Circular and Climate Neutral Industries; the potential successor of SPIRE), could build on the earlier successful cooperation between BBI JU and SPIRE, which succeeded in turning redundancies into synergies¹⁴⁷.

- At national and regional levels, CBE would interact with Member States and regions considering the strategies and plans such as bioeconomy strategies and programmes to advance on synergies and partnering for regional developments¹⁴⁸ for example on synergies with financing instruments and programmes for infrastructure and biorefineries deployment. This will include following up on the recommendations from the BBI JU interim evaluation¹⁴⁹ to increase participation of the EU-13 Member States, which is partially expected via the above-mentioned synergies with the BIOEAST initiative.
- On the international level, many stakeholders suggested that CBE could be kept open to the international players, especially to technology and research leaders and providers, in order to benefit from collaborations with them, and ensure a European leading role in the international development of the bio-based economy. CBE could follow up on the existing recommendations from the interim evaluation of the BBI JU initiative, to identify win-win strategies for a larger involvement of Third Countries while ensuring the protection of EU industry's interests¹⁵⁰.

Finally, it is worth adding that a favourable policy framework is an important factor for the viability of new bio-based value chains and innovations, especially if markets fail to provide sufficient incentives to pick them up. CBE could contribute to the regulatory aspects¹⁵¹ and contribute to harmonising standards¹⁵², developing Life Cycle Assessment methodologies that could support these standards or products, and develop project assessment processes. It can also support expanding the market for bio-based products and solutions by promoting green public procurement. This could contribute to raise awareness, identify regulatory bottlenecks and provide success stories to address regulatory aspects.

¹⁴³ Central-Eastern European Initiative for Knowledge-based Agriculture, Aquaculture and Forestry in the Bioeconomy.

¹⁵² The open public consultation shows that around 60% of the respondents see this as very relevant or relevant for CBE.

5 WHAT ARE THE AVAILABLE POLICY OPTIONS?

This section describes the specific functionalities that could be provided under the baseline scenario of traditional Horizon Europe calls and under the other possible forms of implementation for the proposed initiative.

5.1 What is the baseline from which options are assessed?

The baseline scenario used in this impact assessment is the basic mode of implementation of the EU R&I programme, i.e. traditional calls without any partnership structure with the industry. This scenario takes into account the existence of the predecessor of this initiative – the BBI JU. The existing BBI JU partnership will continue to have impact through ongoing projects and continuous engagement with the industrial actors at least for the next 4 years, until 2024. This impact is considered as part of the effectiveness of the baseline scenario. Winding up of the BBI JU will have also different costs and benefits that are accounted for in the efficiency assessment of the baseline scenario.

Stakeholder opinion

During the preparation of the Impact Assessment, Member states were also consulted. Overall there is a strong agreement (96%) on the use of a partnership approach for a Circular bio-based Europe and a broad agreement (83%) that the partnership is more effective than traditional calls in achieving the objectives and delivering clear impacts for the EU and its citizens.

Table 1: Key characteristics of the baseline situation – Horizon Europe calls

	Implications of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none">• The Commission needs to consult extensively with a wide range of stakeholders to translate the strategic R&I agenda for the circular bio-based economy into work programmes.• A well-defined process is needed to ensure that the programme committees are properly informed about R&I priorities for the circular bio-based economy.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none">• Implementation relies on standard infrastructure underpinning the open calls procedure, drawing on resources of relevant executive agencies and Commission IT systems.• Administrative costs for the European Commission are similar to those in Horizon 2020.• Calls for proposals are published in the work programmes of Horizon Europe.• Transparency and open publication of results ensure their availability to all interested parties.

Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • Strategic programming and the research agenda are defined by the European Commission via co-creation, with the support of an advisory group and the programme committee. • Work programmes need to reflect the requirement for R&I across TRLs, with input from representatives of all relevant stakeholders. • Commission input into specifications and oversight of calls help ensure alignment with overarching policy objectives, but full integration with other programmes requires additional coordination. • Specification of calls for activities at higher TRLs, particularly demonstration and flagship actions, needs substantial input from industry.
Securing leveraging effects (additionality)	<ul style="list-style-type: none"> • Pooling and leveraging of resources are not facilitated. Requirements for in-kind contributions can be applied at the project level (reduced funding rates for higher TRLs), but are not high. • The progress of the R&I effort largely depends on EU funding, with no expectation of a significant triggering of additional industry support. • Demonstration and flagship projects require significant in-kind support and collaboration from industry, but it is not sure whether critical mass can be reached. • Given more limited funding than in the past, critical R&I priorities need to be identified from the outset.
Key differences compared to the current situation	<p>Moving from the current BBI JU to Horizon Europe calls (baseline option) would entail the dismantling of the JU with the following consequences:</p> <ul style="list-style-type: none"> • The implementation of a common vision and ambitious objectives in the area would not be possible due to the absence of a structured private partner. • The basis for R&I cooperation under a stable structure would disappear. • Large scale R&I actions (flagships) could not be implemented, affecting the coverage of TRL 7-8 and diminishing the impact of the initiative. • EU support to the area would considerably lower the leveraging of private funding, with a much lower volume of resources available due to significantly lower financial commitment of private partners. • Discontinuation cost, with a 4-year winding down period for the current JU until 2024 (legal end point of current initiative), will be higher (see rationale at 6.2 Efficiency).

5.2 Description of the policy options

Table 2: Key characteristics of Option 1 – Co-Programmed European Partnership

	Implications of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • Option 1 enables participation by all key stakeholders potentially contributing to the specifications and delivery of the strategic R&I agenda. • A wide range of stakeholders needs to be consulted to ensure that the R&I agenda, and ultimately the work programmes, are aligned with industry and market needs. • There is more flexibility to change the profile of the stakeholder groups consulted over time, with new partners joining to support new areas of activity in response to emerging results and changing priorities. This is notwithstanding to the openness principle. • The partnership is based on a memorandum of understanding between the private partner

	<p>represented by the industry and the public side represented by the Commission. Strategic programming and the research agenda are defined through co-creation between industry, Commission and relevant stakeholders including programme committee and advisory groups.</p>
<p>Supporting implementation of R&I agenda (activities)</p>	<ul style="list-style-type: none"> • Implementation relies on standard administrative infrastructure underpinning the open calls procedure, drawing on resources of relevant executive agencies and Commission IT systems. • Administrative costs for the European Commission are slightly higher than under the baseline because of the needed partnering process. • Calls for proposals are published in the work programmes of Horizon Europe. • Transparency and open publication of results ensure their availability to interested parties. • The private partner is responsible for implementing its part of the research agenda.
<p>Ensuring alignment with R&I agenda (directionality)</p>	<ul style="list-style-type: none"> • Work programmes need to reflect the requirement for R&I activities across TRLs, with input from the various partners to achieve an appropriate balance of activities directed towards different markets. • The partnership is responsible of ensuring that priorities for calls are specified in line with R&I priorities defined in the Strategic Research and Innovation Agenda. • R&I activities are likely to focus on the medium-term needs of the industry, but the Commission has full influence on where to put its own focus. • The programme committee ensures alignment with overarching policy objectives and coordination with related programmes.
<p>Securing leveraging effects (additionality)</p>	<ul style="list-style-type: none"> • Aspirations for partner contributions are clearly defined from the outset. • Industry commitments are not legally binding, but based on past experiences they are usually fulfilled. • Expected in-kind contributions from the private sector are identified in the work programmes. • The mobilisation of private and public funding is more favourable in a co-programmed form than under the baseline scenario, covering all relevant TRL levels including more capital intensive ones.
<p>Key differences compared to the current situation</p>	<p>Moving from the current BBI JU to Option 1 - Co-programmed European Partnership would entail the dismantling of the JU with the following consequences:</p> <ul style="list-style-type: none"> • The implementation of a common vision and ambitious objectives in the area would be less efficient and take longer. • Reach and mobilise R&I actors from different scientific disciplines would pose a challenge for a co-programmed partnership. • Without a programme office, reaching national and regional authorities would be less favourable than with a dedicated office, additionally a co-programmed option would create worse conditions for market uptake of new innovative bio-based solutions. • The basis for R&I cooperation under a stable structure would disappear. • Discontinuation cost, with a 4-year winding down period for the current JU until 2024 (legal end point of current initiative), will be comparable to the baseline (see rationale at 6.2 Efficiency)

Table 3: Key characteristics of Option 3b – Institutionalised European Partnership based on Article 187 TFEU

	Implications of option
Enabling appropriate profile of participation (actors involved)	<ul style="list-style-type: none"> • The partnership enables participation of all key stakeholders potentially contributing to the specifications and delivery of the strategic R&I agenda through a clearly defined membership structure. • It provides a forum for co-drafting R&I priorities and the work programmes, ensuring that they are aligned with industry and market needs. • Participation is less flexible than under other options, but it is nevertheless possible to change the profile of participation over time, with an open Membership policy and new partners joining to support new areas of activity in response to emerging results and changing priorities.
Supporting implementation of R&I agenda (activities)	<ul style="list-style-type: none"> • A dedicated administrative structure (Joint Undertaking – JU) is established to coordinate the specification of R&I activities, manage implementation, and report on the results (with administrative expenditure limited to 4% of the budget and subject to 50:50 allocation between the Commission and private partners). • The Joint Undertaking provides specific thematic competences for the implementation of the initiative and deploys a broader range of activities, compared to what the executive agencies supervising projects under Option 0 and 1 can provide. • To reach and mobilise R&I actors from different scientific disciplines, a Joint Undertaking provides a favourable platform for multidisciplinary projects. • Under the umbrella of a programme office, public and private R&I activities that are programmed to ensure the desired directionality to R&I in bio-based innovation perform better than in a co-programmed form of partnership.
Ensuring alignment with R&I agenda (directionality)	<ul style="list-style-type: none"> • Both partners, private and the Union, are co-responsible for specifying work programmes that are fully in line with the R&I priorities identified by the partners beforehand to fulfil European policy needs and the needs of the industry, combining activities across low and high TRLs and in different areas. • The work programmes reflect the medium- to long-term needs of the industry, drawing on the perspectives of different stakeholders. • Commission participation in the partnership governance (including work programme adoption) helps ensure alignment with overarching policy objectives and enables integration with other programmes. • R&I activities focus on issues of public interest. In an Institutionalised format this refers to the environmental performance of the bio-based industry – both in the terms of understanding the relevant problems and developing solutions to them.
Securing leveraging effects (additionality)	<ul style="list-style-type: none"> • Formal commitments and funding requirements are clearly defined from the outset and are legally binding (contributions are defined in the legal act), with the private partners expected to provide 50% to 75% of partnership resources through in-kind and financial contributions. • Given more limited funding than in the past, critical R&I priorities need to be identified from the outset. • A Joint Undertaking can assist in de-risking private investment by using public funds to co-finance close to market projects.
Key differences compared to the current situation	<p>Remaining an Institutionalised Partnership under Art 187 TFEU 1 - would entail:</p> <ul style="list-style-type: none"> • The CBE partnership would build on the BBI JU structure, allowing for necessary improvements by drawing on lessons learned and past experiences. • Modifications will be introduced in administrative procedures and practices to ensure that operations are lean and efficient as possible.

- Setting scientifically robust sustainability criteria and performance benchmarks, and apply them in all publicly funded R&I activities in the bio-based industry and to all projects supported by the initiative, and promote these criteria beyond the initiative, by agreeing with the private partners that these criteria will become de facto industrial standards to be observed by the industry on voluntary basis.
- The governance structure of the CBE initiative would include two major improvements compared to the current BBI JU.
 - The role of the Deployment Groups is to advise the Governing Board on issues critical to market uptake of bio-based innovation and to promote deployment of sustainable bio-based solutions. Their composition shall ensure appropriate thematic focus and representativeness of the bio-based innovation stakeholders.
 - In addition to the general Governing Board meetings, the Governing Board shall hold at least once per year a Strategic Meeting with the primary objective to identify challenges and opportunities for sustainable bio-based industry and provide additional strategic orientation for the partnership. In the Strategic Meeting additional chief executive officers or officers with decision-making power of leading European bio-based companies and the Commission, shall be invited. The chairpersons of the States Representative Group, the Scientific Committee and the Deployment Groups may be invited in the role of observers.

5.3 Options discarded at an early stage

Option 2: Co-funded European Partnership and **Option 3a: Institutionalised Partnership based on Article 185 TFEU** are discarded from the outset.

These two partnership models exclude industries in the partnership agreement, which does not create any basis for involving them in the R&I agenda setting and does not provide adequate incentives for industries to commit to the policy objectives and to programme success. In achieving the key objectives of securing long-lasting competitiveness of the European bio-based industries and ensuring their circularity and sustainability, it is necessary to have involvement and commitment of the industries concerned.

Furthermore, the limited possibility of connecting various sectors would fail to deliver the structuring effect that is highly needed for the development of the EU bio-based industry and of new value chains. This is especially the case with the value chains that could potentially valorise waste biomass by integrating providers of e.g. agricultural and forestry waste, food waste, fisheries waste or urban waste in the production of novel bio-based products.

6 HOW DO THE DIFFERENT POLICY OPTIONS COMPARE TO ACHIEVE THE EXPECTED IMPACTS?

Based on the intervention logic, the initiative aims to deliver scientific, economic/technological and environmental (including societal) impacts through a set of pathways (Section 4.3), which require a number of critical factors in place for the impacts to be

achieved in the best possible way (Section 4.4). In what follows, each option for implementation is assessed in terms of effectiveness, efficiency and coherence compared to the baseline scenario of traditional calls. The analysis is primarily based on the degree to which the different options would cater for the key needed functionalities. All options are compared to the baseline situation of traditional calls, which is thus consistently scored at 0 to serve as reference point.

6.1 Effectiveness

To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. This section considers to which extent the different policy options would allow delivering these expected impacts – comparing what is needed (functionalities) with what each form of implementation can provide in practice. The assessments in this section set the basis for the comprehensive comparative assessment of all retained options against all dimensions in Section 6.4, based on a scoring system.

Scientific impacts

- Accelerated development of bio-based innovations;
- Reinforced scientific and innovation capacity for bio-based solutions, including in the regions where this capacity is currently underdeveloped;
- Increased R&I capacity for addressing the key sustainability challenges.

The baseline option:

A significant scientific impact can be achieved under the baseline scenario. Through traditional Horizon Europe calls, it is possible to set priorities and directionality for R&I activities through strategic programming. Adequate financing can be mobilised for grants targeting low- to medium-TRL projects. However, financing of capital intensive high-TRL projects can be limited because of insufficient mobilisation of private investment under this option. The baseline scenario can also effectively contribute to long-term scientific progress by investing in novel exploratory and interdisciplinary research (score 0).

The scientific and innovation capacity in general will be reinforced under the baseline scenario but there is limited possibility to target those R&I partners and regions where the capacity is currently underdeveloped. Calls for projects are open, which implies that anyone could potentially benefit. However, the interim evaluation of Horizon 2020 and the experience with the predecessor partnership indicate that traditional calls tend to largely attract actors that are already active in public R&I support programmes. Many relevant bio-based stakeholders, e.g. biomass producers, bio-waste recyclers, SMEs, etc., especially in the regions where the bio-based industry is less developed, may not have information or capacity to participate in the calls. Lack of capacity and the absence of support structures facilitating outreach (such as from a JU programme office) would be a barrier. Therefore, this option is unlikely to achieve the desired strong impact in terms of diversity of actors and in terms of targeting the underdeveloped regions (score 0).

Finally, the baseline scenario is able to contribute to knowledge development in the area of sustainability through the strategic programming process (score 0).

Option 1 – Co-programmed partnership:

A co-programmed European partnership can deliver more in terms of the scientific impact, mainly due to a higher amount of resources pooled in the programme via contributions of partners and better representation of relevant actors and stakeholders. A co-programmed partnership has also greater capacity than the baseline to support high-TRL projects (demonstrations and flagships) due to the action of private industrial partners. It can effectively set priorities and give directionality to R&I activities, while aligning the public and private R&I agendas (score +).

The co-programmed partnership is flexible in terms of involvement of different partners and can attract and facilitate participation of a wider scope of actors and stakeholders; however it would most likely not specifically target stakeholders and regions with underdeveloped capacity (score +).

The ability to focus the R&I activities on sustainability issues is comparable to the baseline of traditional Horizon Europe calls (score 0).

Option 3b – Institutionalised European Partnership based on Article 187 TFEU:

Similar to the co-programmed partnership, an institutional partnership under Article 187 can deliver more on the scientific impact than the baseline scenario, mainly due to a higher amount of resources pooled in the programme via contributions of partners and better representation of relevant stakeholders. A co-programmed partnership has the greatest capacity to support high-TRL projects due to co-funding of these projects by public and private partners (score +).

It can effectively set priorities and give directionality to R&I activities, while aligning the public and private R&I agendas. Due to the institutionalised form and formal financial commitments by partners, it is less flexible in terms of involvement of different partners but can effectively target specific key stakeholders (primary biomass producers, SMEs) and regions with underdeveloped capacity (score ++).

The ability to focus the R&I activities on sustainability issues is comparable to the baseline scenario (score 0).

Stakeholder opinion:

46% of OPC 1782 respondents (industry, academic and research institutions, public authorities and NGOs) answered that a legal structure would have a very high relevance in terms of achieving certain impacts such as effective implementation of activities; synergies with other EU and national programmes; and collaboration with other European partnerships.

Economic/technological impacts

- Bio-based innovations reaching first market application and bringing real economic and environmental benefits;
- A structured process for collaboration between R&I actors, industry including SMEs and other bio-based innovation stakeholders focused on the deployment of bio-based innovation;
- Reduced investment risk and improved access to finance for bio-based industrial projects.

The baseline option:

The baseline scenario has a limited ability to support the market application of bio-based innovation, due to limited resources for large scale, capital-intensive flagship projects, and the absence of mechanisms for collaboration with important deployment stakeholders such as regional authorities or investors. Market uptake is supported mainly by indirect dissemination activities (score 0).

The baseline scenario does not have a structuring effect on the dynamic bio-based industry and no possibility to facilitate business innovation through collaboration along and across bio-based value chains (score 0).

The baseline scenario does not have any tools to address the investment risk for bio-based projects other than generic R&I investment tools and calls planned under the Horizon Europe (score 0).

Option 1 – Co-programmed European Partnership:

A co-programmed partnership has much higher capacity than the baseline scenario to implement capital-intensive demonstration and flagship projects through the actions of private partners. The commitment of partners is however voluntary, and comes without guarantees that the investment actually happens (score +).

The co-programmed partnership can develop a well organised process for collaboration and structuring of the industry. This form of implementation foresees the possibility to establish bodies and processes that will involve relevant partners and facilitate collaboration and business innovation based on bio-based solutions. However, without a more institutionalised form and dedicated structures, this process may not be effective enough to reach the intended objectives (score +).

The co-programmed partnership can also address some investment risks. For instance, by involving the investment community, raising awareness of available bio-based solutions and their techno-economic parameters, or by involving regulatory stakeholders to address some regulatory risks. The co-programmed partnership cannot directly de-risk projects implemented by the private partners (score +).

Option 3b – Institutionalised European Partnership based on Article 187 TFEU:

The institutionalised partnership has much higher capacity than the baseline scenario to implement capital-intensive demonstration and flagship projects through the joint actions of public and private partners. This joint action and co-financing by partners guarantees better than the other options that the investment happens and projects are implemented (score ++).

The institutionalised partnership can develop a well-organised process for collaboration and structuring of the industry. The institutionalised partnership establishes a dedicated body with the capacity to assist the structuring process and to target the relevant actors from industry. It can also involve other deployment stakeholders, e.g. regional authorities, primary biomass producers, and so on in a more formal and structured way, aiming at the creation of favourable conditions for deployment of bio-based innovation. This dedicated body with the necessary expertise and capacity is the key to the effectiveness of these activities (score ++).

The institutionalised partnership can tackle some of the investment risk, e.g. by involving the investment community, raising awareness of the bio-based solutions and their techno-economic parameters, or by involving regulatory stakeholders to address some regulatory risks. In addition, the co-financing of the demonstration and flagship projects from EU funds

helps to de-risks the private investment in these projects and may attract and convince other investors invest in these projects (score ++).

Stakeholder opinion

With respect to the relevance of coordination, alignment or integration with specific stakeholders' groups in pooling and leveraging resources (such as financial, infrastructure, in-kind expertise etc.) to meet Partnership objectives, the patterns in stakeholders' responses are very similar. In the Open Public Consultation, 76% of respondents from all stakeholder groups (industry, academic and research institutions, public authorities and NGOs) indicated that industry was very relevant. Member States and Associated Countries (54%) were also found to be very relevant. As regards academia, the share of respondents that found their involvement very relevant was somewhat lower (42%) Most of the respondents among different stakeholder groups did not indicate Foundations and NGOs as very relevant (21%).

Environmental/Societal impacts (social, fundamental rights)

- Enhanced circularity and environmental sustainability of the European bio-based industries;
- Better integration of primary biomass producers in bio-based value chains to contribute to rural development.

The baseline option:

Under the baseline scenario, it is possible to develop sustainability criteria and benchmarks and apply them to all the bio-based projects funded by the EU R&I programme. This scenario does not have any mechanism to enforce or promote the application of sustainability criteria outside of Horizon Europe operations, e.g. by privately funded projects (score 0).

As the baseline scenario has only a limited capacity to integrate primary biomass producers such as farmers in the high-TRL projects and limited structuring effect, it cannot effectively integrate farmers in the bio-based value chains. It is unlikely that this scenario will have significant positive effect on farmers' income and on rural development (score 0).

Option 1 – Co-programmed European Partnership:

Under the co-programmed partnership, the application of sustainability criteria can be guaranteed for the publicly funded R&I actions. Other partners may respect sustainability criteria on a voluntary basis (score 0).

The co-programmed partnership also allows for the involvement of primary biomass producers and can integrate their interest and needs in the activities of the partnership (score +).

Stakeholder opinion

81% of the 207 respondents to the Open Public Consultation (industry, academic and research institutions, public authorities and NGOs) stated that it is either relevant or very relevant to create jobs in the bio-based industry in rural and underdeveloped areas.

Option 3b – Institutionalised European Partnership based on Article 187 TFEU:

Under the institutionalised partnership, the application of sustainability criteria can be guaranteed for the all co-funded R&I actions (the Commission holds a veto power on the

formulation of co-financed calls). The institutionalised form could also foster the acceptance of the sustainability criteria by the industrial partners also beyond the operation of the partnership as an industrial benchmark (score +).

The institutionalised partnership allows for the involvement of primary biomass producers and can integrate their interest and needs in the activities of the partnership. Moreover, the institutionalised partnerships have a designated body that could actively target primary biomass producers so as to integrate them in the partnership activities. (score +)

Impacts on fundamental rights

Impacts on fundamental rights are not expected.

Stakeholder opinion

In the Open Public Consultation, respondents (industry, academic and research institutions, public authorities and NGOs) were asked about the relevance of the Partnership composition, such as the flexibility in the composition of partners over time and the involvement of a broad range of partners (including across disciplines and sectors), to reach Partnership objectives. No statistical differences were found between the views of citizens and other types of respondents.

Ensuring the involvement of a broad range of partners has more ‘very relevant’ answers (67%) than the flexibility in the composition of partners (48%).

Table 4: Overview of the options’ effectiveness compared to the baseline

	Baseline: Horizon Europe calls	Option 1: Co- programmed European Partnership	Option 3b: Institutionalised Article 187 TFEU
Accelerated development of bio-based innovations	0	+	+
Reinforced scientific and innovation capacity for bio-based solutions including in the regions where currently this capacity is underdeveloped	0	+	++
Increased R&I capacity for addressing the key sustainability challenges	0	0	0
Bio-based innovations reaching first market application and bringing real economic and environmental benefits	0	+	++
A structured process for collaboration between R&I actors, industry including SMEs and other bio-based innovation stakeholders focused on deployment of bio-based innovation	0	+	++
Reduced investment risk and improved access to finance for bio-based industrial projects	0	+	++
Enhanced circularity and environmental sustainability of the European bio-based industries	0	0	+
Better integration of primary biomass producers in bio-based value chains to contribute to rural development	0	+	+

Notes: Score ++ : Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.2 Efficiency

In order to compare the policy options consistently in terms of their efficiency, a standard cost model was developed for the external study supporting the impact assessment for the set of candidate Institutionalised Partnerships. The model and the underlying assumptions and analyses are set out in the Common Part of this impact assessment, Section 2.3.2 and in the Methodology Annex 4. A dedicated Annex 3 also provides more information on who is affected and how by this specific initiative in line with the Better Regulation framework. The scores related to the costs set out in this context allow for a “value for money” analysis (cost-effectiveness) in the final scorecard analysis in Section 6.4.

In addition, for this specific initiative under the baseline scenario of traditional calls, there would be winding down and social discontinuation costs for the existing implementation structure of the current Article 187 initiative. There would also be longer term financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. Overall it is estimated that the overall longer term cost savings from using traditional calls instead of an existing Article 187 initiative would considerably exceed the costs incurred for winding down operations. This overall situation is set as the starting point for the comparison of options. The score of this baseline scenario (traditional Horizon Europe calls) is set to 0 to be used as a reference point.

On this basis, the scores for the costs of the different options range from a value of 0, in case an option does not entail any additional costs compared to the baseline, to a score of (-) when an option introduces limited additional costs when compared to the baseline and a score of (- -) when high additional costs are expected in comparison with the baseline. In case the scores are lower than for the baseline scenario, (+) and (++) are used. For option 1, additional costs for the call and project implementation have been considered. It has been taken into account that for option 3b there are moderate additional costs for the setup of a dedicated implementation structure, as such a structure (BBI JU programme office) already exists.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed options – and the least cost-efficient – the Institutionalised Partnership option. Indeed, in terms of cost-efficiency, the Co-Programmed Partnership (Option 1) is 2 percentage points more efficient than the baseline; while an Article 187 Partnership is 2 percentage points less cost-efficient than the baseline. A score of + is therefore assigned for **cost-efficiency** to the Co-Programmed option and a score of (-) for the Institutionalised Partnership policy option¹⁵³.

It should be noted that the potential for the creation of crowding-in effects for industry has been taken into account when assessing the effectiveness of the policy options, above.

Table 5: Matrix on overall costs and cost-efficiency

¹⁵³ The baseline (traditional calls) is scored 0, as explained above.

	Option 0: Traditional calls under the Framework Programme	Option 1: Co-programmed European Partnership	Option 3b – Institutionalised European Partnership based on Article 187 TFEU
Administrative, operational and coordination costs	0	0	--
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	+	-

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline.

6.3 Coherence

6.3.1 Internal coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with other actions, programmes and initiatives under Horizon Europe, in particular European Partnerships (internal coherence).

Baseline: Horizon Europe Calls

Coherence of the research agenda is likely to be achieved. However, complementarities are limited by the smaller number of actions at higher TRLs, leading to a loss of knowledge transfer from R&I actions to demonstration and deployment activities. This will be reinforced by the lack of continuity in projects teams, as answers to individual calls usually lead to ad-hoc consortia. There will be a limited scope for synergies between projects, as there is a lack of structuring of the community in the absence of a dedicated body. Synergies and complementarities with the rest of Horizon Europe are likely to be achieved. Links with other partnerships⁽¹⁵⁴⁾ or EIT-KICs⁽¹⁵⁵⁾ could be made, but they would be ad hoc. The lack of a dedicated team that engages with other partnerships limits the creation of links and might result in duplication or misalignment of work (score 0)

Option 1 – Co-programmed European Partnership:

The Memorandum of Understanding (MoU) envisaged under this option ensures the coherence of the R&I agenda over time. In addition, the flexibility of the governance model would secure the timely involvement of the most relevant actors, ensuring continuity across projects and best internal synergies. As the European Commission retains a strong steering role, coherence with the rest of Horizon Europe is achieved. Both Commission staff and the network's secretariat theoretically have the means to create synergies and complementarities with other partnerships⁽¹⁵⁴⁾ or KICs⁽¹⁵⁵⁾, but this depends on the availability and expertise of the staff, and good coordination between them. Its score would therefore be higher than the baseline (score +).

Option 3b – Institutionalised European Partnership based on Article 187 TFEU:

¹⁵⁴ Safe and Sustainable Food System for People, Planet & Climate; Carbon Neutral and Circular Industry; Rescuing Biodiversity; Water4All.

¹⁵⁵ Food; Climate; Raw Materials; Manufacturing.

The institutionalised partnership provides for the creation of a dedicated secretariat (programme office) with specialised staff with a complete understanding of bio-based issues and who would have the means to fully exploit the potential for synergies and complementarities of all actors. It also acts as a single contact point for interested parties. An institutionalised partnership can count on a stronger contribution from industrial partners, secured through a legal agreement, which benefits project partners and ensures a strong structuring effect. The research agenda has to be fully in line with Horizon Europe objectives and therefore coherence with the rest of Horizon Europe is ensured. With the resources to engage with other European partnerships⁽¹⁵⁴⁾ or KICs⁽¹⁵⁵⁾, an institutionalised partnership is able to exploit synergies and complementarities within Horizon Europe. As explained by a majority of interviewees, this is the option with the highest visibility and strongest position to engage with other parties. Its score would therefore be very high compared to the baseline (score ++).

Stakeholder opinion

Some 59% of the 1782 respondents to the Open Public Consultation (industry, academic and research institutions, public authorities and NGOs) consider that setting up a specific legal structure for the proposed initiative Circular Bio-based Europe is either relevant or very relevant.

6.3.2 External Coherence

In this section we assess the extent to which the policy options have the potential of ensuring and maximising coherence with their external environment, including EU-level programmes and initiatives beyond the Framework Programme and/or national and international programmes and initiatives, but also with overarching framework conditions, such as regulation, standardisation, etc. (external coherence).

Baseline: Horizon Europe Calls

Links can theoretically be made with other programmes under the Multiannual Financial Framework 2021-27 (MFF) (beyond Horizon Europe), but on an ad-hoc basis. Under the baseline, there is no dedicated team that could devolve time to engage with other programmes to develop structured, long-lasting synergies. Nonetheless, activities that are unlikely to be carried out through Horizon Europe calls (especially deployment actions) could be envisaged to be funded under other programmes (e.g. InvestEU). Horizon Europe calls are unlikely to contribute to setting up infrastructure, and projects would have to rely on their infrastructure to be provided by other funders.

The absence of Horizon Europe funding for biorefineries impacts on the capacity to conduct research, as other funders are unlikely to match the missing element, leading to a loss of complementarity. No work on regulation can be expected via Horizon Europe calls, and their capacity to contribute to the debate through Coordinating and Support Actions (CSA) is limited. Especially, the results of CSAs in this domain, as well as overall directionality and engagement of the community, might be impeded by the lack of a community structuring effect, scattered actors with highly diverse opinions, and no clear overall identification of needs (score 0).

Option 1 – Co-programmed European Partnership:

The administration of the partnership by an EC executive agency ensures that staff has the means to continuously engage with other programmes beyond Horizon Europe to develop synergies and complementarities. The network’s secretariat can also take part in this bridge-making. A wider range of actors involved in the network can create the conditions for stronger synergies with other public bodies at European, national or regional level. Continued alignment with national and regional strategies can be ensured, as under the BBI JU⁽¹⁴¹⁾. However, in a co-programmed partnership the industry might be less engaged, an issue frequently raised by interviewees (especially companies). It would therefore not benefit from strong complementarities with purely private initiatives, and might attract less attention from brand owners. Overall, its score would be high compared to the baseline (score +).

Option 3b – Institutionalised European Partnership based on Article 187 TFEU:

A strong involvement of the European Commission will be needed to ensure that an institutionalised partnership engages with other Multiannual Financial Framework (MFF) programmes. However, the need to look for complementarities, especially regarding access to finance when demonstration and deployment activities end, creates a strong incentive for the programme office of the partnership to engage with these programmes (e.g. EIB’s European Circular Bioeconomy Fund, InvestEU). In addition, it would have the resources to then support project holders in their transition. The proposed initiative could set up a ‘one-stop’ contact point for interested parties to make them aware of the availability of the different funding sources, and of the possibility to combine (more easily) different funding sources.

Involving a wide set of actors within the network who benefit from the structuring effect of an institutionalised partnership, creates the conditions for synergies with other public bodies at European, national, regional and local level. The high level of involvement required of the industry would also encourage them to join forces and develop the links that are necessary to create and strengthen bio-based value chains in an integrated manner. The structuring effect of an institutionalised partnership also provides for the constitution of a common understanding of needs, especially of regulation, infrastructure or human capital. Overall, this options scores very high compared to the baseline (score ++).

Table 6: Overview of the options’ potential for ensuring and maximising coherence

	Option 0	Option 1	Option 3b
Internal coherence	0	+	++
External coherence	0	+	++

Score ++: Option presenting a very high potential; Score +: Option presenting a high potential; Score 0: Potential of baseline

6.4 Tabular comparison of options and identification of preferred option

The table below gives a summary of the comparative analysis done above. The table given in Technopolis’ Impact Assessment Study Report has been corrected and developed further.

Table 7: Ranking of the policy options

	Criteria	Option 0 – Traditional calls under the Framework Programme	Option 1 – Co-programmed European Partnership	Option 3b – Institutionalised European Partnership based on Article 187 TFEU
Effectiveness	Accelerated development of bio-based innovations	0	+	+
	Reinforced scientific and innovation capacity for bio-based solutions including in the regions where currently this capacity is underdeveloped	0	+	++
	Increased R&I capacity for addressing the key sustainability challenges	0	0	0
	Bio-based innovations reaching first market application and bringing real economic and environmental benefits	0	+	++
	A structured process for collaboration between R&I actors, industry including SMEs and other bio-based innovation stakeholders focused on deployment of bio-based innovation	0	+	++
	Reduced investment risk and improved access to finance for bio-based industrial projects	0	+	++
	Enhanced circularity and environmental sustainability of the European bio-based industries	0	0	+
	Better integration of primary biomass producers in bio-based value chains to contribute to rural development	0	+	+
Coherence	Internal coherence	0	+	++
	External coherence	0	+	++
Efficiency	Overall cost	0	0	--
	Cost-efficiency	0	+	-

Score ++: High performance; Score +: Medium performance; Score 0: same performance as baseline; Score (-) = limited additional costs compared with the baseline; Score (-)(-) = substantial additional costs compared with the baseline.

The ranking shows that the baseline option performs less well against all dimensions and criteria compared to options 1 and 3b. Even though it reached a higher score against the overall cost criterion, this does balance against its lower performance against all other criteria. The ranking also shows that options 1 scores lower than 3b in various respects. Option 3b is higher overall and more advantageous regarding its expected impacts.

The assessment concludes with a preference for option 3b, the institutionalised partnership. However, considering the challenges faced in implementing the BBI JU, the lessons learned (see section 1.2) have to be taken into account while transiting to a CBE initiative, both on content and on implementation, for example as follows:

- The initiative needs to broaden the scope of its activities and strengthen synergies, while enlarging the range of actively involved stakeholders;
- The private partner of CBE should include representatives of all bio-based economy actors;
- The industrial partners should interact more with other actors in the value chains and help to develop a favourable ecosystem for the bio-based industry as a whole;
- In particular, primary producers such as farmers, foresters, fishermen and producers of biomass from aqueous environments need to be better represented by involving their representatives as partners. In addition, one could reflect about involving representatives of municipalities and waste collectors as partners or in specific fora;
- A more balanced decision-making process would be needed, where diverse stakeholder voices, also from outside the industry, are heard and considered in shaping the research agenda. Better synergies with national and regional developments have to be built, by involving regional authorities in the partnership and its governance;
- The partnership’s environmental and socio-economic impact has to be measured constantly and not only ex post;
- The KPIs have to be assessed more accurately beforehand to better reflect what can be achieved by the initiative, and the corporate IT tools need to accommodate for such reporting;
- Biodiversity protection could be mentioned as one of the objectives of the partnership, which could lead to involving more biodiversity specialists in the governance of the partnership, for example in the scientific committee;
- A system has to be put in place to ensure that a situation is avoided in the future in which the private members are unable to fulfil their obligation related to financial contributions. Given the revised Model Finance Regulation, there should be a clear understanding with partners from the very beginning that they have sustainable and reliable long-term sources that will allow them to contribute financially to the administrative costs of the new partnership;
- The complicated way of reporting the private partner’s in-kind contributions to operational and additional costs has to be simplified.

Box 4 - Comparison between the preferred option & the current partnership existing in the area taking into account lessons from past evaluations

What continues	What is different
<ul style="list-style-type: none"> • Art 187 Union Body, with EC as Founding Member • Strong link with Bio-based Industries • Structuring of the fragmented European bio-based industry • Building on the momentum established by the high participation of the SME sector • Close collaboration between the scientific community and industry • Most of the projects expect to contribute to job creation, as around half of them are located in rural and coastal areas • Better synergies with other Horizon Europe and national initiatives • Systemic approach to collaborative research • Overall partner composition involving many segments of the bio-based industry and SMEs • Long term financial commitments from the industrial partner. 	<ul style="list-style-type: none"> • Broaden the scope of present activities and strengthen synergies • Improved governance system ensuring better representation of stakeholders and protection of the public interest • Increased focus on sustainability and circularity of bio-based solutions, including utilisation of waste, side-streams and residues as feedstock for bio-based industry • Better involvement of the agricultural primary sector • Better involvement of European regional authorities • Definition of new KPIs.

Regarding the improved governance mentioned above, the Commission will exercise its power as the member of the Governing Board of the partnership and ensure that the new partnership will respond to the recommendations from the evaluation of its predecessor as well as to concerns raised over the balance of public and private interest in partnership operation. The governance will in particular improve in the following aspects:

- Openness, transparency and representativeness: the partnership has to represent (through the private partner) the whole bio-based industry and relevant bioeconomy actors (e.g. farmers and other primary biomass producers).
- Integration and protection of public interest: The public interest will be clearly formulated and anchored in the Strategic Research and Innovation Agenda (SRIA) and operational documents (Annual Work Programmes). This includes that sustainability criteria and benchmarks are met by all projects supported by the partnership.
- Effectiveness in achieving the objectives: All bodies of the partnership will collaborate in programming, implementation and monitoring of activities to maximise the impact. New formations of stakeholders important for deployment of bio-based innovation (e.g. regional authorities and investors) – deployment groups – will be formed to assist the partnership in acceleration of market application of bio-based innovation.

7 THE PREFERRED OPTION - HOW WILL ACTUAL IMPACTS BE MONITORED AND EVALUATED?

7.1 The preferred option

In Table 8, below, the alignment of the preferred option of Institutionalised European Partnership under Article 187 TFEU with the selection criteria for European Partnerships defined in Annex III of the Horizon Europe Regulation is depicted. Seeing that the design process of the candidate Institutionalised Partnerships is not yet concluded and several of the related topics are still under discussion, the criteria of additionality/directionality and long-term commitment are covered in terms of *expectations* rather than *ex-ante* demonstration.

Table 8: Alignment with the selection criteria for European Partnerships

Criterion	Alignment of the preferred option
Higher level of effectiveness	The Institutionalised Partnership is more effective than the Horizon Europe calls in achieving the related objectives of the programme through involvement and commitment of industry partners, as well as engaging other actors (Member States, regions, academia and civil society organisations) through a governance model that needs to be more participative than the one that is currently operated in the BBI JU.
Coherence and synergies	Coherence and synergies of the Institutionalised Partnership within the EU research and innovation landscape will be ensured through the formal agreements between the proposed initiative and other initiatives, as well as through the co-creative process of the agenda setting and dedicated efforts in the course of implementation by the support team.
Transparency and openness	The preferred option offers an adequate level of transparency and openness in the selection of priorities and objectives and the involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international actors (when relevant and not interfering with European competitiveness). Formalised procedures will offer clear modalities for promoting SME participation, as well as for disseminating and exploiting results.
Additionality and directionality	The preferred option offers high additionality, namely high potential for structuring the bio-based industries and ensures directionality by formalising commitments of partners toward achieving specific targets, eventually feeding high-level policy objectives.
Long-term commitment	In the case of Institutionalised European Partnerships, established in accordance with Article 187 TFEU, the financial and/or in-kind contributions from partners other than the Union will at least be

Criterion	Alignment of the preferred option
	equal to 50 % and may reach up to 75 % of the aggregated European Partnership budgetary commitments. It is expected that most of the commitment will be realised via in-kind and, to a lesser extent, financial contributions within projects, rather than at the programme level.

7.2 Objectives and corresponding monitoring indicators

7.2.1 Operational objectives

To deliver on the general and specific mid- and long-term objectives, the proposed CBE partnership aims to achieve several operational objectives in the short term. These also include activities going beyond R&I and that can be implemented under Horizon Europe. This reflects the definition of European Partnerships in the Horizon Europe regulation as initiatives where the Union and its partners “commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”

For each of the specific objectives, the following operational objectives could be identified:

(a) to reap the benefits of the advancement in life sciences and in other scientific disciplines for the development and demonstration of sustainable bio-based solutions

- Support interdisciplinary research projects advancing the development, experimentation, demonstration and deployment of bio-based industrial solutions;
- Mobilise corporate and national R&I actors to fund research and innovation action in bio-based innovation;
- Coordinate and align EU, national and corporate R&I strategies to give R&I in bio-based solutions appropriate priority.

(b) to increase and integrate the R&I capacity of stakeholders across the Union to develop more sustainable bio-based innovations

- Support the regional R&I actors in the development of their R&I programs, smart specialisation strategies, rural development programmes and other relevant strategic plans to prioritise the bio-based sector;
- Engage regional R&I actors to participate in EU funded collaborative projects to facilitate transfer of skills and competences;
- Support research action to better understand the environmental performance and risks of the bio-based industry and bio-based industrial systems;
- Support R&I actions that integrate sustainability aspects in the innovation development along the whole innovation chain;
- Develop technology solutions to the problems that currently prevent low quality heterogeneous biological waste from use as a feedstock for bio-based industry.

(c) to reinforce the integration of bio-based R&I processes in EU industrial value chains

- Establish a mechanism that will facilitate collaboration between R&I and industrial actors;
- Support national and regional authorities to develop their bioeconomy strategies and policies to create favourable environment for deployment of bio-based innovation;
- Support demonstration and flagship projects involving industrial actors.

(d) To reduce the risk for R&I investment in bio-based companies and projects

- Support R&I actions to improve techno-economic performance of bio-based systems;
- Support R&I actions that address the scientific and technological issues related to biomass feedstock and that are source of concerns for stability of supply;
- Recommend measures to national and regional policy makers that can reduce the risk to investment and improve access to finance for bio-based projects;
- Facilitate collaboration between R&I and industrial actors to create new value chains to develop markets and demand for bio-based products;
- Step up co-financing, together with industry and/or with private investors, of the first market application projects (flagships).

(e) to ensure environmental considerations are taken into account in the development and implementation of R&I bio-based projects

- Develop sustainability criteria for all relevant levels of decision-making in the bio-based sector through a collaborative R&I action;
- Apply the sustainable criteria to all EU funded R&I projects in the bio-based industry;
- Negotiate with the bio-based industry a voluntary commitment that the EU sustainability criteria will be accepted as the industry standard and observed by industry in their activities outside of publicly funded R&I projects;
- Promote the sustainability criteria among national and regional authorities so that they are applied in their policy actions including bioeconomy strategies and financial incentives through the CAP and regional development funds.

7.2.2 Monitoring indicators

The table below suggests a number of possible key monitoring indicators for tracking the progress of the initiative towards its specific objectives in addition to the ones identified for the Horizon Europe key impact pathways.

Table 9: Monitoring indicators in addition to the Horizon Europe key impact pathway indicators

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
Scientific impact	N of scientific publications from CBE projects N of participants from the regions with limited bio-based R&I capacity N of projects addressing the sustainability knowledge gap	N of patents from CBE projects N of CBE projects with new technologies demonstrated	N of technologies and products patented or demonstrated in CBE that reached the market and have been commercialised Scientific performance of the EU increases in international statistics on bio-based and circular economy
Technological / economic impact	N of new circular bio-based building blocks identified N of new circular bio-based value-chains created N of new biorefineries set up N of new circular bio-based products created	N of jobs created as a result of the new value chains, technologies and (commercialised) products Value added created as a result of the new value chains, technologies and	Economic performance indicators (turnover, export, etc.) of the EU increases in international statistics on bio-based and circular economy or products Performance of the EU on

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
	N of new feedstock suppliers engaged in projects or new value chains N of new cross-sectoral collaborations	(commercialised) products N / % of regions with new building blocks, value chains, biorefineries and products	sustainable biomass production and sustainable use of bio-waste improved. Investments in the EU of in the circular bio-based industry increased
Societal impact	N of feedstock suppliers reached by information campaigns on opportunities of the bio-based and circular economy N of new feedstock suppliers in CBE projects N of SMEs engaging in CBE projects N of activities on streamlining regulations, standards and certifications	N of new feedstock suppliers engaged in new value chains N of regulations, standards and certifications schemes improved by CBE results, tested and/or launched	Global performance of the EU in creation of high-quality jobs in the circular bio-based economy increased Increased income of primary producers active in the circular bio-based sector
Environmental impact	New ways of bio-waste valorisation (or diversion from discard) introduced New ways to avoid CO ₂ emissions avoidance or new carbon sink functions More efficient biomass use processes introduced Sustainable primary production practices introduced as parts of new value chains	Tons of biomass waste valorised or diverted from discard Tons of CO ₂ emissions avoided or sunk Change (%) in efficiency of biomass use per ton of bio-based product Square km of land on which sustainable agricultural or forestry practice is envisaged to be introduced as part of new value chains	Diffusion of sustainable practices on biomass and waste valorisation beyond CBE projects National and regional climate neutrality improved Circular economy targets approached Biodiversity enhancement observed as a result of sustainable biomass supply to bio-based value chains Ecosystem services improved or emerged as a result of sustainable biomass supply to bio-based value chains

7.2.3 Evaluation framework

The evaluation of the Partnership will be done in full accordance with the provisions laid out in Horizon Europe Regulation Article 47 and Annex III, with external interim and ex-post evaluations feeding into the overall Horizon Europe evaluations. As set in the criteria for European Partnerships, the evaluations will include an assessment of the most effective policy intervention mode for any future action; and the positioning of any possible renewal of the Partnership in the overall European Partnerships landscape and its policy priorities. In the absence of renewal, appropriate measures will be developed to ensure phasing-out of Framework Programme funding according to conditions and timeline agreed with the legally committed partners ex-ante.

1. LEAD DG, DECIDE PLANNING REFERENCES

Lead DG: Directorate General Research and Innovation (RTD)

Decide number: PLAN/2019/5305

2. ORGANISATION AND TIMING

Institutionalised partnerships are foreseen in Articles 185 and 187 of the Treaty on the Functioning of the European Union (TFEU). The preliminary agreement on Horizon Europe contained a list of possible areas for institutionalised partnerships based on Article 185 and 187. For each of these areas the Commission considered 12 potential institutionalised partnerships. Their set up involves new EU legislation and the establishment of dedicated implementing structures and therefore an impact assessment for each of these initiatives.

Following political validation in June 2019, the impact assessment process started with the publication of inception impact assessments for each initiative in August 2019.

An inter-service steering group (ISSG) on research and innovation partnerships under Horizon Europe was set up in May 2019 and held 4 meetings before submission of the Staff Working Document to the Regulatory Scrutiny Board (7 May 2019, 19 June 2019, 5 December 2019, 20 January 2020). The ISSG consisted of representatives of the Secretariat-General, Directorate-General for Budget, Directorate-General for Research and Innovation Directorate-General for Communications Networks, Content and Technology, Directorate-General for Mobility and Transport, Directorate-General for Internal Market, Industry, Entrepreneurship and SMEs, Directorate-General for Energy, Directorate-General for Environment, Directorate-General for Climate Action, and the Legal Service.

An online public stakeholder consultation was launched between September and November 2019, gathering 1635 replies for all 12 initiatives.

3. CONSULTATION OF THE RSB

Two upstream meetings with the Regulatory Scrutiny Board of were held on 10 July 2019 and 30 September 2019.

In accordance with the feedback received from the Regulatory Scrutiny Board on 12.06.2020 the Staff Working Document has been revised as presented in Figure 1. These revisions were endorsed by the Inter Service Steering Group on 27.07.2020.

4. EVIDENCE, SOURCES AND QUALITY

To ensure a high level of coherence and comparability of analysis for all candidate initiatives, an external study was procured to feed into the impact assessments of the 12 candidate

institutionalised partnerships ¹ (Technopolis Group, 2020). It consisted of an horizontal analysis and individual thematic analyses for each of the initiatives under review.

For all initiatives, the evidence used includes desk research partly covering the main impacts and lessons learned from previous partnerships. A range of quantitative and qualitative data sources complement the evidence base, including evaluations; foresight studies; statistical analyses of Framework Programmes application and participation data and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options. Public consultations (open and targeted) supported the comparative assessment of the policy options. For each initiative up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition the analysis was informed by the results of the Open Public Consultation (Sep – Nov 2019), the consultation of the Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of candidate Institutionalised European Partnerships.

A more detailed description of the methodology and evidence base used, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

Figure 1 Modifications to the draft Staff Working Document based on comments received from the Regulatory Scrutiny Board

Responses to the positive opinion with reservations of the Regulatory Scrutiny Board	
(B) Summary of findings	
Despite improvements, the intervention logic is still not specific to the circular bio-based economy and does not focus on the choice of the type of partnership.	Section 5.2 Description of the policy options has been further improved to clarify the best form of partnership for this initiative, and links with the intervention logic are clarified.
Conclusions from evaluating the predecessor partnership are more present in the report, but they do not directly feed into the problem definition, the intervention logic, and the choice of options.	Box 3 'Support for the field in the previous Framework Programmes – key strengths & weaknesses identified' under section 1.2 on EU relative positioning in the field explains how the continuous evaluation of the predecessor partnership BBI JU was carried out since its set-up in 2014. As a result, the new CBE initiative builds on the success of its predecessor while having evolved by learning from its shortfalls. These learnings

¹ Technopolis Group, 2020, forthcoming.

	are now better reflected in the problem definition, the intervention logic and choice of options.
The report does not always present the different and sometimes critical stakeholders' opinions.	The stakeholders' opinions are highlighted throughout the report. The diverging views of the Member States are now also presented under section 5.1 What is the baseline from which options are assessed.
(C) What to improve	
The central point of the assessment, i.e. the choice of the best form of a research partnership for the circular bio-based economy, is still largely absent from the intervention logic. This makes assessing different types of partnerships difficult, as the link between options, problems and objectives is not properly established.	<p>The main shortfall in the intervention logic was the missing link between the objectives and options (i.e. forms of partnership). The description of options included in the first version of the Impact Assessment followed closely the descriptive characteristics of options set for all R&I partnerships in the common part of the IA. The relevance of these characteristics for achieving the CBE objectives was therefore, not obvious.</p> <p>To address this point, an additional description specifically related to objectives and functionalities was added to the tables in section 5.2. Thus the link between objectives and options was reinforced. This description is also a basis for scoring options later in the text.</p>
The problem description should better integrate the results of the evaluation of the current partnership. These include a number of organisational issues that are directly relevant for the choice of the best form of research partnership.	In the intervention logic the organisational issues identified in the evaluation of the current partnership are related to the functionalities necessary for achievement of objectives. New elements of description were added to the tables in section 5.2 on how different types of partnership are able to deal with these organisational issues.
The report should better explain the functioning and expected performance of the governance systems foreseen under	There are elements of governance that are intrinsically linked to policy options (forms of partnership) and other elements of

<p>each option. For instance, it should explain how these systems would help secure sufficient private sector financial contributions. It should also better describe what the different partners would contribute to the partnership, other than finance. It should also describe how the governance systems would address the potential risk of industry capture.</p>	<p>governance that are choices within each policy option. The former are now described in section 5.2. The latter are described for the preferred policy option in section 6.4. The risk of industry capture will be mitigated by explicit formulation of public interest objectives and their integration into strategic/programming documents and operational rules.</p> <p>The Commission is committed to use its power as a member of the Governing Board to ensure (a) transparency and representativeness of the partnership; (b) definition of public interests in the partnership and their integration into the SIRA and programming documents (Annual Work Programmes); and (c) improvement of effectiveness, among others by involving other innovation stakeholders through ‘deployment stakeholders groups’.</p>
<p>The report should further clarify the scoring system and in particular the relative importance of the different criteria. It should better justify and explain the assessment of options against the different criteria.</p>	<p>The scoring is better justified by new elements of description of policy options that are related to functionalities and the ability to achieve objectives.</p>
<p>The report should more comprehensively present different stakeholder views. In particular, it should include more critical voices throughout the report. The Board notes that the estimated costs and benefits of the preferred option in this initiative, as summarised in the attached quantification tables.</p>	<p>The current version of the Impact Assessment report deals with two main criticisms by non-industrial stakeholders (see, for example, the critical report by the Corporate Europe Observatory). The criticism related to potential environmental impacts (land use change, impact on biodiversity and carbon emissions, etc.) is now addressed by the new general objective to ensure a high level of environmental performance of bio-based industry with related specific and operational objectives. The concern that the partnership may serve the interest of the private partner and less the public interests is addressed through the requirement on the governance of the future partnership (section 6.4).</p> <p>Stakeholders’ opinions are highlighted throughout the report. The diverging views of</p>

	the Member States are now also presented under section 5.1 on What is the baseline from which options are assessed.
(D) Conclusion DG RTD must revise the report in accordance with the Board's findings before launching the interservice consultation. If there are any changes in the choice or design of the preferred option in the final version of the report, the DG may need to further adjust the attached quantification tables to reflect this.	
There report was revised to take account of the Boards comments. There were no changes made with regard to the choice or the design of the preferred option.	

Annex 2 Stakeholder Consultation

1. OVERVIEW FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1.1. Introduction

In line with the Better Regulation Guidelines,² the stakeholders were widely consulted as part of the impact assessment process of the 12 candidates for institutionalised partnerships, including national authorities, the EU research community, industry, EU institutions and bodies, and others. These inputs were collected through different channels:

- A feedback phase on the inception impact assessments of the candidate initiatives in August 2019, gathering 350 replies for all 12 initiatives on the “Have your say” web portal during a period of 3 weeks;
- A structured consultation of Member States performed by the EC services over 2019 through the Shadow Strategic Configuration of the Programme Committee of Horizon Europe (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.
- An online public stakeholder consultation administered by the EC, based on a structured questionnaire, open between September and November 2019, gathering 1635 replies for all 12 initiatives;
- A targeted consultation run by the external study contractors with a total of 608 interviews performed as part of the thematic studies by the different study teams between August 2019 and January 2020.

1.2. Horizontal results of the Open Public Consultation

The consultation was open to everyone via the EU Survey online system.³ The survey contained two main parts to collect views on general issues related to European partnerships (in Part 1) and specific responses related to one or more of the 12 candidate initiatives (as selected by a participant). The survey was open from 11 September till 12 November 2019. The consultation was available in English, German and French and advertised widely through the European Commission’s online channels as well as via various stakeholder organisations.

1.2.1. Profile of respondents

In total, 1635 respondents filled in the questionnaire of the open public consultation. Among them, 272 respondents (16.64%) were identified to have responded to the consultation as part of a campaign (coordinated responses). Based on the Better Regulation Guidelines, the groups of respondents where at least 10 respondents provided coordinated answers were labelled as ‘*campaigns*’, segregated and analysed separately and from other responses. In total 11

² https://ec.europa.eu/info/files/better-regulation-guidelines-stakeholder-consultation_en

³ <https://ec.europa.eu/eusurvey/runner/ConsultationPartnershipsHorizonEurope>

campaigns were identified, the largest of them includes 57 respondents⁴⁴. In addition, 162 respondents in the consultation also display similarities in responses but in groups smaller than 10 respondents. Hence, these respondents were not labelled as campaigns and therefore were not excluded from the general analysis.

Table 1: Country of origin of respondents (N=1635)

Country	Number of respondents	Percentage of respondents
Germany	254	15.54%
Italy	221	13.52%
France	175	10.70%
Spain	173	10.58%
Belgium	140	8.56%
The Netherlands	86	5.26%
Austria; United Kingdom	61	3.73%
Finland	49	3.00%
Sweden	48	2.94%
Poland	45	2.75%
Portugal	32	1.96%
Switzerland	28	1.71%
Czechia	24	1.47%
Greece	23	1.41%
Norway; Romania	22	1.35%
Denmark	20	1.22%
Turkey	19	1.16%
Hungary	14	0.86%
Ireland	12	0.73%
United States	11	0.67%
Estonia; Slovakia; Slovenia	10	0.61%
Bulgaria; Latvia	9	0.55%
Bosnia and Herzegovina	7	0.43%
Lithuania	4	0.24%
Canada; Croatia; Israel	3	0.18%
China; Ghana; Iceland; Japan; Luxembourg; Morocco	2	0.12%
Bhutan; Botswana; Cyprus; Iran; Malta; Mexico; Moldova; Mongolia; Palestine; Russia; Serbia; South Africa; Tunisia; Ukraine; Uruguay	1	0.06%

As shown in Figure 2, the three biggest **categories of respondents** are representatives of companies and business organisations (522 respondents or 31.9%), academic and research institutions (486 respondents or 29.7%) and EU citizens (283 respondents or 17.3%). Among the group of respondents that are part of campaigns, most respondents are provided by the same groups of stakeholders, namely company and business organisations (121 respondents or 44.5%), academic and research institutions (54 respondents or 19.8%) and EU citizens (42 respondents or 15.4%).

⁴⁴ The candidate Institutionalised Partnership Clean Hydrogen has the highest number of campaigns, namely 5. A few initiatives, such as Innovative SMEs, Smart Networks and Systems, were not targeted by campaigns. Some campaign respondents decided to provide opinions about several partnerships.

Figure 2 Type of respondents (N=1635) - For all candidate initiatives

Among all consultation respondents, 1303 (79.69%) have been **involved in the on-going research and innovation framework programme** Horizon 2020 or the preceding Framework Programme 7, while 332 respondents (20.31%) were not. In the group of campaign respondents, the share of those who were involved in these programmes is higher (245 respondents out of 272 or 90.07%) than in the group of non-campaign respondents (1058 out of 1363 or 77.62%). When respondents that participated in the Horizon 2020 or in the preceding Framework Programme 7 were asked to indicate in which capacity they were involved in these programmes, the majority stated they were a beneficiary (1033 respondents) or applicant (852 respondents). The main stakeholder categories, e.g. companies/business organisation, academic/research institutions, etc., show a similar distribution across the capacities in which they ‘have been involved in Horizon 2020 or in the Framework Programme 7’ as the overall population of consultation respondents.

Among those who have been involved in Horizon 2020 or the preceding Framework Programme 7, 1035 respondents (79.43%) are/were **involved in a partnership**. The share of respondents from campaigns that are/were involved in a partnership is higher than for non-campaign respondents, 89.80% versus 77.03% respectively. The list of partnerships under Horizon 2020 or its predecessor Framework Programme 7 together with the numbers, percentages of participants is presented in Table 4 **Error! Reference source not found.**, the table also show the key stakeholder categories for each partnership. Most consultation respondents participated in the following partnerships: Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, Clean Sky 2 Joint Undertaking, European Metrology Programme for Innovation and Research (EMPIR) and in Bio-Based Industries Joint Undertaking. The comparison between the non-campaign and campaign groups of respondents shows that the overall distribution is quite similar. However, there are some differences. For the campaign group almost a half of respondents is/was involved in the Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, a higher share of campaign respondents is/was participating in Clean Sky 2 Joint Undertaking and in Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking.

When respondents were asked in which **role(s) they participate(d) in a partnership(s)**, over 40% indicated that they act(ed) as partner/member/beneficiary in a partnership. The second largest group of respondents stated that they applied for funding under a partnership. The roles selected by non-campaign and campaign respondents are similar.

Table 4: Partnerships in which consultation respondents participated (N=1035)

Name of the partnership	Number and % of respondents from both groups (n=1035)	Number and % of respondents from a non-campaign group (n=815)	Academic/research institutions	Business associations	Company/business organisations	Company/business organisations	EU citizens	NGOs	Public authority
Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking	354 (33.33%)	247 (30.31%)	97	9	37	43	41	8	5
Clean Sky 2 Joint Undertaking	195 (18.84%)	145 (17.79%)	57	2	10	27	37	1	7
European Metrology Programme for Innovation and Research (EMPIR)	150 (14.49%)	124 (15.21%)	64	0	13	9	14	2	19
Bio-Based Industries Joint Undertaking	142 (13.72%)	122 (14.97%)	39	8	20	27	14	1	6
Shift2Rail Joint Undertaking	124 (11.98%)	101 (12.40%)	31	7	5	31	14	3	7
Electronic Components and Systems for European Leadership (ECSEL) Joint Undertaking	111 (10.72%)	88 (10.80%)	42	2	7	20	12	0	5
Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking	66 (6.38%)	46 (5.64%)	10	3	3	20	3	2	3
5G (5G PPP)	53 (5.12%)	47 (5.77%)	20	1	6	14	5	0	1
Eurostars-2 (supporting research-performing small and medium-sized enterprises)	44 (4.25%)	40 (4.91%)	17	0	6	1	7	0	6
Innovative Medicines Initiative 2 (IMI2) Joint Undertaking	37 (3.57%)	35 (4.29%)	18	2	3	3	2	4	3
Partnership for Research and Innovation in the Mediterranean Area (PRIMA)	28 (2.71%)	26 (3.19%)	15	0	3	1	2	0	2
European and Developing Countries Clinical Trials Partnership	25 (2.42%)	24 (2.94%)	12	0	1	2	3	3	2
Ambient Assisted Living (AAL 2)	22 (2.13%)	21 (2.58%)	11	2	1	1	3	0	3
European High-Performance Computing Joint Undertaking (EuroHPC)	22 (2.13%)	18 (2.21%)	6	0	2	3	5	0	2

For the remaining of the consultation respondents could provide their views on each/several of the candidate initiatives. The majority of respondents (31.4%) provided their views on the Clean Hydrogen candidate partnership. More than 45% of respondents from the campaigns selected this partnership. Around 15% provided their views for European Metrology, Clean Aviation and Circular Bio-based Europe. The share of respondents in the campaign group that chose to provide views on the Clean Aviation candidate partnership is of 20%. The smallest number of respondents provided opinions on the candidate initiative ‘EU-Africa research partnership on health security to tackle infectious diseases – Global Health’.

Table 5: Candidate Institutionalised Partnerships for which consultation respondents provide responses (N=1613)

Name of the candidate Institutionalised European partnership	Number and % of respondents from both groups (n=1613)	Number and % of respondents from a non-campaign group (n=1341)
Clean Hydrogen	506 (31.37%)	382 (28.49%)
European Metrology	265 (16.43%)	225 (16.78%)
Clean Aviation	246 (15.25%)	191 (14.24%)
Circular bio-based Europe	242 (15%)	215 (16.03%)
Transforming Europe’s rail system	184 (11.41%)	151 (11.26%)
Key Digital Technologies	182 (11.28%)	162 (12.08%)
Innovative SMEs	111 (6.88%)	110 (8.20%)
Innovative Health Initiative	110 (6.82%)	108 (8.05%)
Smart Networks and Services	109 (6.76%)	107 (7.98%)
Safe and Automated Road Transport	108 (6.70%)	102 (7.61%)
Integrated Air Traffic Management	93 (5.77%)	66 (4.92%)
EU-Africa research partnership on health security to tackle infectious diseases – Global Health	49 (3.04%)	47 (3.50%)

1.2.2. Characteristics of future candidate European Partnerships

Respondents were asked to assess what areas, objectives, aspects need to be in the **focus of the future European Partnerships** under Horizon Europe and to what extent. According to Figure 6, a great number of respondents consider that a significant contribution by the future European Partnerships is ‘fully needed’ to achieve climate-related goals, to the development and effective deployment of technology and to EU global competitiveness in specific sectors/domains. Overall, respondents’ views reflect that many aspects require attention of the Partnerships. The least attention should be paid to responding towards priorities of national, regional R&D strategies, including smart specialisation strategies, according to respondents.

Overall, only minor differences can be found between the main stakeholder categories. Academic/research institutions value the responsiveness towards EU policy objectives and focus on development and effective deployment of technology a little less than other respondents. Business associations, however, find that the future European Partnerships under Horizon Europe should focus a little bit more on the development and effective deployment of

technology than other respondents. Furthermore, business associations, large companies as well as SMEs value the role of the future European Partnerships for significant contributions to EU global competitiveness in specific sectors domains a little higher than other respondents. Finally, both NGOs and Public authorities put a little more emphasis on the role of the future European Partnerships for significant contributions to achieving the UN SDGs. The views of citizens (249, or 18.3%) do not reflect significant differences with other types of respondents. However, respondents that are/were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7 assign a higher importance of the future European Partnerships to be more responsive towards EU policy objectives and to make a significant contribution to achieving the UN’s Sustainable Development Goals.

A qualitative analysis of the “other” answers highlights the importance of collaboration and integration of relevant stakeholders to tackle main societal challenges and to contribute to policy goals against which fragmentation of funding and research efforts across Europe should be avoided. Additionally, several respondents suggested that faster development and testing of technologies, acceleration of industrial innovation projects, science transfer and market uptake are needed. Next to that, many respondents provided answers related to the hydrogen and the energy transition, which corresponds to the high number of respondents that provided answers to the candidate initiative on this topic.

Figure 6: To what extent do you think that the future European Partnerships under Horizon Europe need to (N=1363) (non-campaign replies) For all candidate initiatives

1.2.3. Main advantages and disadvantages of Institutionalised European Partnerships

An open question asked to outline the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe (1551 respondents). The advantages mentioned focus on the development of technology, overall collaboration between industry and research institutions, and the long-term commitment. Disadvantages mentioned are mainly administrative burdens. An overview is provided below.

Advantages mentioned: Long term commitment, stability, and visibility in financial, legal, and strategic terms; Participation of wide range of relevant stakeholders in an ecosystem (large/small business, academics, researchers, experts, etc.); Complementarity with other (policy) initiatives at all levels EU, national, regional; Efficient and effective coordination and management; High leverage of (public) funds; Some innovative field require high levels of international coordination/standardisation (at EU/global level); Ability to scale up technology (in terms of TRL) through collaboration; Networking between members; Direct communication with EU and national authorities

Disadvantages mentioned: Slow processes; System complexity; Continuous openness to new players should be better supported as new participants often bring in new ideas/technologies that are important for innovation; Lower funding percentage compared to regular Horizon Europe projects; Cash contributions; Administrative burdens; Potential for IPR constraints.

1.2.4. Relevance of EU level to address problems in Partnerships' areas

Respondents were asked to rate the **relevance of research and innovation efforts at EU level efforts to address specific problems in the area of partnerships**. Research and innovation related problems were rated as most relevant across all candidate initiatives, followed by structural and resources problems and problems in the uptake of innovations. Overall, all three areas were deemed (very) relevant across the partnerships, as more than 80% of respondents found these challenges (very) relevant. Only minor differences were found between stakeholder categories. Research and innovation problems were found slightly more relevant by academic/research institutions, yet slight less relevant by large companies and SMEs. Structural and resource problems were indicated as slightly more relevant by NGOs, but slightly less by academic/research institutions. While both NGOs and public authorities find slightly more relevant to address problems in uptake of innovation than other respondents. The views of citizens are not differing significantly. Respondents that are/were directly involved in a current/preceding partnership find, however, the need to address problems related to the uptake of innovations slightly more relevant than other respondents.

Figure 9: To what extent do you think this is relevant for research and innovation efforts at EU level to address the following problems in relation to the candidate partnership in question? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.5. Horizon Europe mode of intervention to address problems

Respondents were asked to indicate how these challenges could be addressed through **Horizon Europe intervention**. Just over 50% of all respondents indicated that institutionalised partnerships were the best fitting intervention, with relatively strong differences between stakeholder categories. The use of Institutionalised Partnership was indicated more by business associations and large companies, but less by academic/research institutions and SMEs. While academic/research institutions valued traditional calls more often, this was not the case for business associations, large companies and public authorities. Public authorities indicated a co-programmed intervention more often than other respondents. Citizens indicated slightly less often that institutionalised partnerships were the best fitting intervention. Respondents that are/were directly involved in a current/preceding partnership, selected the institutionalised partnership intervention in far higher numbers (nearly 70%).

Figure 10: In your view, how should the specific challenges described above be addressed through Horizon Europe intervention? (non-campaign replies) For all candidate initiatives

When asked to reflect on their answers, respondents that pointed to the need for using institutionalised partnership mentioned the long-term commitment of collaboration, a common and ambitious R&I strategy as well as the overall collaboration between industry and research institutions. Others shared positive experiences with other modes of interventions:

- Traditional calls, because of their flexibility and integration of a wide range of actors, as long as the evaluation panels do not deviate from the policy focus. This was mentioned by 94 participants, including companies (25), academics (26) and EU citizens (25).
- Co-funded partnership, as a mechanism to ensure that all participants take the effort seriously, while allowing business partnerships to develop. This approach was deemed suitable based on previous experiences with ERANETs. This was raised by 84 participants, 36 of them academic respondents, 18 companies and 16 EU citizens.
- Co-programmed partnerships, to tackle the need to promote and engage more intensively with the private sector. This was mentioned by 97 participants, most of them companies (34), followed by academics (22), business associations (15) and EU citizens (11).

1.2.6. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Setting joint long-term agendas

Respondents were asked how relevant it is for the proposed European Partnerships to meet their objectives to have a strong involvement of specific stakeholder groups in setting joint long-term agenda. All respondents see stakeholders from industry as the most relevant,

followed by academia and governments. The involvement of foundations and NGOs as well as other societal stakeholders were, however, still found to be (very) relevant by more than 50% of the respondents. Most respondents indicated the stakeholder group they belong to themselves or that represent them as relevant to involve.

Figure 11: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Setting joint long-term agenda with strong involvement of: (non-campaign replies) For all candidate initiatives

Pooling and leveraging resources through coordination, alignment and integration with stakeholders

Respondents were asked how relevant it is for the proposed European Partnership to meet its objectives to pool and leverage resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with specific groups of stakeholders. Respondents see stakeholders from industry as the most relevant, followed by academia and governments (Member States and Associated Countries). The involvement of foundations and NGOs as well as other societal stakeholders are also still found to be (very) relevant for more than 50% of the respondents. Similarly as described for the question on setting joint long-term agendas, most stakeholder categories valued their own involvement higher than other respondents – although also here differences between stakeholder categories were minor.

Figure 12: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Pooling and leveraging resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with: (non-campaign replies) For all candidate initiatives

Composition of the partnerships

Regarding the composition of the partnership most respondents indicated that for the proposed European Partnership to meet its objectives the composition of partners needs to be flexible over time and that a broad range of partners, including across disciplines and sectors, should be involved (see Figure 13). When comparing stakeholder groups only minor differences were found. Academic/research institutions and public authorities found the involvement of a broad range of partners and flexibility in the composition of partners over time slightly more relevant than other respondents, while large companies found both less relevant. SMEs mainly found the flexibility in the composition of partners over time less relevant than other respondents, while no significant differences were found regarding the involvement of a broad range of partners. Citizens provided a similar response to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, indicated a slightly lower relevance of the involvement of a broad range of partners and flexibility in the composition of partners over time.

Figure 13: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Partnership composition (non-campaign replies) Aggregation of responses of all candidate initiatives

Implementation of activities

Most respondents indicated that implementing activities like a joint R&I programme, collaborative R&I projects, deployment and piloting activities, providing input to regulatory aspects and the co-creation of solutions with end-users are all (very) relevant for the partnerships to be able to meet its objectives. Minor differences were found between the main stakeholder categories, the differences found were in line with their profile. As such, academic/research institutions found joint R&I programme & collaborative R&I projects slightly more relevant and deployment and piloting activities, input to regulatory aspects and co-creation with end-users slightly less relevant than other respondents. For SMEs an opposite pattern is shown. Large companies, however, also found collaborative R&I projects slightly more relevant than other respondents, as well as input to regulatory aspects. The views of citizens are similar to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, show a slightly higher relevance across all activities.

Figure 14: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Implementing the following activities (non-campaign replies) For all candidate initiatives

1.2.7. Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Respondents were asked to reflect on the relevance of setting up a legal structure (funding body) for achieving a set of improvements, as shown in the Figure below. In general, 70%-80% of respondents find a legal structure (very) relevant for these activities. It was found most relevant for implementing activities in a more effective way and least relevant for ensuring a better link to practitioners on the ground, however differences are small.

Figure 15: In your view, how relevant is to set up a specific legal structure (funding body) for the candidate European Partnership to achieve the following? (non-campaign replies) Aggregation of responses of all candidate initiatives

When comparing stakeholder categories there are only minor differences. Academic/research institutions indicated a slightly lower relevance for transparency, better links to regulators as well as obtaining the buy-in and long-term commitment of other partners. SMEs also indicated a lower relevance regarding obtaining the buy-in and long-term commitment of other partners. Large companies showed a slightly higher relevance for implementing activities effectively, ensure better links to regulators, obtaining the buy-in and long-term commitment of other partners, synergies with other EU/MS programmes and collaboration with other EU partnerships. NGOs find it slightly more relevant to implement activities faster for sudden market or policy needs. Public authorities, however, find it slightly less relevant to facilitate collaboration with other European Partnerships than other respondents. The views of citizens show a slightly lower relevance for a legal structure in relation to implementing activities in an effective way. Respondents that are/were directly involved in a current/preceding partnership indicated a higher relevance across all elements presented.

1.2.8. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Consulted on the scope and coverage for the partnerships, based on their inception impact assessments, the large majority feels like the scope and coverage initially proposed in the inception impact assessments is correct. However, about 11% to 15% of the respondents indicated the scope and coverage to be too narrow. About 11%-17% of respondents answered “Don’t know”. Overall, differences between the main stakeholder categories were found to be minor. Academic/research institutions indicated slightly more often that the research area was “too narrow” than other respondents. SMEs on the other hand indicated slightly more often that the research area and the geographical coverage were “too broad”. NGOs and public authorities, however, found the geographical coverage slightly more often “too narrow”. Large companies found the range of activities slightly more often “too broad” and the sectoral focus slightly more often “too narrow” when compared to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership more often indicated that the candidate institutionalised European Partnership have the “right scope & coverage”.

Figure 16: What is your view on the scope and coverage proposed for this candidate institutionalised European Partnership, based on its inception impact assessment? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.9. Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

When asked whether it would be possible to rationalise a specific candidate European Institutionalised Partnership and its activities, and/or to better link with other comparable initiatives, nearly two thirds of respondents answered “Yes” (1000, or 62%), while over one third answered “No” (609, or 39%). Nearly no differences were found between stakeholder categories, only large companies and SMEs indicated slightly more often “Yes” in comparison to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership, indicated “No” more often, the balance is about 50/50 between “Yes” and “No” for this group.

1.2.10. Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Finally, respondents were asked to rate the relevance of partnership specific impacts in three main areas: Societal; Economic/technological; and Scientific impacts. All three areas were deemed (very) relevant across the candidate partnerships. Scientific impact was indicated as the most relevant impact, more than 90% of respondents indicated that this as (very) relevant. Only minor difference between stakeholder groups were found. Academic/research institutions found scientific impacts slightly more relevant, while large companies found economic and technological impacts slightly more relevant than other respondents. NGOs found societal impact slightly more relevant, while SMEs found this slightly less important. Citizens did not a significantly different view when compared to other respondents. Respondents that are/were directly involved in a current/preceding partnership find all impacts slightly more relevant than other respondents.

Figure 17: In your view, how relevant is it for the candidate European Institutionalised Partnership to deliver on the following impacts? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.3. Stakeholder consultation results for this specific initiative

1.3.1. Feedback to the inception impact assessment on candidate initiatives for Institutionalised Partnerships

Following the publication of the inception impact assessment, a feedback phase of 3 weeks allowed any citizen to provide feedback on the proposed initiatives on the “Have your say” web portal. In total 340 feedbacks were collected for all initiatives.

For the initiative “Circular Bio-Based Europe” 19 individual feedbacks were collected, mainly from businesses (2 responses), business associations (6 responses), academic institutions (5 responses, including 2 anonymous), public authorities (3 responses) and NGOs (3 responses).⁵ Among the elements mentioned were:

- Eight stakeholders (all businesses, two business associations, three academic institutions, one NGO and two public authorities) welcomed the integration of circular economy objective and highlighting the high relevance of the circular economy topic in the context of biobased industries
- Eight stakeholders (all businesses, some business associations, over half academic institutions, one public authority) commented on the model of the new initiative and welcomed the Institutional Partnership model. Comments included that this model represents the deepest level of integration and engagement; that it is the best way forward as it will contribute to longevity and sustainability, through integration, engagement. Some mentioned positive experience and the proven efficiency of the current Bio-based Industries Joint Undertaking structure. Some stakeholders commented on the commitment issue, and noted that only IP provides the legal means to ensure the private partner meets a defined minimum level of commitments.
- One public authority stakeholder while supporting the IP model, commented on importance of assuring an appropriate governance model that is aligned with the public interest, industry needs and the needs of other key stakeholders such as primary producers and end users. They suggest that the role of the MS in the governance is strengthened including via synergies with national programmes, more open process of programme topic generation, information sharing with the MS as in other parts of Horizon, transparency on the real (in-kind and in-cash) contributions actually provided by industry.
- One stakeholder from NGO sector criticized the models of public-private partnerships (ETPs, JTIs, JUs) with industry having an increasing say in determining strategic research agendas and promoting own needs at the expense of EC funds.
- Several stakeholders suggested to ensure that thematic coverage included additional topics as listed below:
 - Three stakeholders commented on importance of inclusion of *bioenergy* sector in the sectorial coverage of the new initiative, commenting that it can also contribute to the circular economy and its synergies with other bio-based sectors.
 - There stakeholders from business, business associations and regional government, stressed the relevance of *wastewater* in the circular bio-based economy as an important source of nutrients and chemicals
 - One association extensively argued about importance of promoting R&I on *plant-based proteins* under the new initiative.

⁵ Feedback on inception impact assessment to be found on https://ec.europa.eu/info/law/better-regulation/initiatives/ares-2019-4972449/feedback_en?p_id=5722347

- One business association suggested to include a focus on *renewable gases* from agricultural waste in the topical scope of the initiatives.
- Two stakeholders (from academia and NGO), highlighted the importance to consider environmental impact of creating new demand for biomass (e.g. food security, impact on ecosystems, resource conflicts outside EU), and ensure maintenance or improvement of biodiversity.

1.3.2. Structured consultation of the Member States on European partnerships

A structured consultation of Member States through the Shadow Strategic Configuration of the Programme Committee Horizon Europe in May/ June 2019 provided early input into the preparatory work for the candidate initiatives (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.

The feedback provided by 30 countries (all Member States, Iceland and Norway) has been analysed and summarised in a report, with critical issues being discussed at the Shadow Strategic Programme Committee meetings.

We can summarise the findings of the report in 6 main takeaways:

- **Overall positive feedback on the proposed portfolio, but thematic coverage could be improved**

The results indicate a high level of satisfaction with the overall portfolio, the level of rationalisation achieved, and policy relevance. While delegations are in general satisfied with the thematic coverage, the feedback suggests the coverage could be improved in cluster 2 “Culture, creativity and inclusive society” and cluster 3 “Civil Security for Society”.

- **Large number (25) of additional priorities proposed for partnerships by delegations**

Despite high satisfaction with the portfolio and candidates put forward by the Commission, countries put forward a high number of additional priorities to be considered as European Partnerships. A closer examination suggests that these additional proposals are motivated by very different reasons. Whilst some proposals are indeed trying to address gaps in the portfolio and reach a critical mass, then, others are driven by the wish to maintain existing networks, currently not reflected in the Commission proposal (e.g. those based on JPIs, ERA-NETs). In addition, some proposals reflect worries over some topics not being sufficiently covered in the existing proposals, but could be possibly well covered within the scope of existing partnerships, or by traditional calls under the Framework Programme.

- **Critical view on the high number and openness of Joint Undertakings**

Country feedback suggests dissatisfaction with the high number of proposed Article 187 TFEU partnerships. Notably smaller as well as EU-13 countries raise concerns with regards to the potential insufficient transparency and openness of the partnership model. In the feedback, countries either directly support or ask to carefully analyse whether the objectives of this proposal could be reached with the co-programmed model.

For those partnerships that will be set up on the basis of Article 187, the country feedback stresses the need to ensure a clear shift towards openness in the governance, membership policy and allocation of funding of these partnerships. Notably, it is emphasised that the JU rules should not have any limitations or entry barriers to the participation of SMEs and other partners, including from academia.

Although the feedback suggests a general criticism, there are few concrete and broadly supported proposals, including to reduce the number of institutionalised partnerships mergers or by alternative implementation modes.

- **Lack of cross-modal perspective and systematic approach to mobility**

The current proposal foresees 5 partnerships in the area of transport (for rail, air traffic management, aviation, connected and automated driving, zero-emission road transport), and 2 that in closely related technologies for radically reducing carbon emissions (hydrogen, batteries). Several delegations would wish to see a systemic approach to developing mobility and addressing related challenges (optimisation of overall traffic, sustainable mobility solutions for urbanisation), and do not support a mode-dependent view only. This suggests the need to discuss how to ensure greater cooperation between transport modes and cross-modal approaches in establishing partnerships in the area of mobility.

- **Partnership composition: the role of Member States in industry partnerships**

The composition and types of partners is an important element for the success of a partnership, e.g. to ensure the right expertise and take-up of results. Ensuring broad involvement without overly complicating the governance of the partnership remains an important challenge in the design of future partnerships.

In the feedback, several Member States express their interest to join as a partner in partnerships that have traditionally been industry-led. However, individual comments suggest there are different views on what their involvement means in practice, with some countries expressing readiness to commit funding, while others support limiting their involvement to alignment of policies and exploiting synergies. This suggests the need to discuss further what the involvement of Member States means in practice (notably in terms of contributions, in the governance), and what would be possible scenarios/options in Horizon Europe. There is special interest in testing and deployment activities, in synergies with Cohesion Funds and CEF priorities and investments.

Although it is too early to determine the interest of industry/ businesses in the topics proposed for partnerships where the main partners are public authorities, their involvement in public centric partnerships will also be an important question in the design and preparation of future proposals.

- **Some proposals are more mature than others**

The analysis of feedback per partnership candidates suggests that some proposals are more mature, while others would need more time to determine the scope, objectives, partner composition and contribution and appropriate mode of implementation. This relates to in particular to partnerships with no predecessors and those where the main partners are public. It suggests that the proposals would need to be developed at different paces in order to achieve good quality, and thus, not all partnership proposals may be ready for implementation at the start of Horizon Europe.

For the initiative “Circular Bio-Based Europe” the following overall feedback was received from Member States. Delegations identified a number of aspects that could be reinforced in the proposal for the "Circular Bio-based Europe" partnership that would increase its relevance for national priorities. They suggest e.g. to broaden the scope towards forestry, waste and marine bio-resources; to give more emphasis to local production of biomass and to create opportunities for the development of local small-scale technological solutions for rural regions and urban areas. The proposed use of Article 187 is supported by 26%, but also questioned by 26% of the responses, with 48% requiring more information. Overall the results of the Member State consultation confirm strongly the high relevance of the proposed European partnership for a Circular bio-based Europe. While 43% of the countries are undecided at this stage, 15 have expressed an interest to participate (BE, DE, ES, FI, FR, CR, HU, IE, IT, MT, NL, RO, SE, SK, SI), and only one country has at this stage expressed that there is no national interest to participate (IS). Overall there is a strong agreement (96%) on the use of a partnership

approach for a Circular bio-based Europe and a broad agreement (83%) that the partnership is more effective than traditional calls in achieving the objectives and delivering clear impacts for the EU and its citizens. The majority of countries indicate good agreement with the proposed objectives at short, medium and long term and the expected scientific, economic and societal impacts at European level.

1.3.3. Targeted consultation of stakeholders

In addition to the consultation exercises coordinated by EC services, the external study thematic teams performed targeted consultations with businesses, research organisations and other partners on different aspects of potential European Partnerships.

Approach to the targeted consultation

The objectives of the interviews in the context of this impact assessment was to collect view of people on the following topics:

- Overall and specific objectives that the potential Circular bio based partnership/initiative could address
- Target groups, membership and openness
- Role and activities of the initiative
- Leverage effect in the potential partnership
- Coordination, structuring and mobilisation needs
- Key Performance Indicators (KPI)
- Costs and benefits of the potential initiative
- Need for a Circular bio-based Europe
- Research needs
- Contribution to EU policies
- Governance / organisation
- Collaborations with other initiatives
- Benefits of EU action

The selection of interviewees was discussed with the steering committee members. The key point was to approach the actors who are well informed about the ongoing partnership work either by being involved in projects, governance board or cooperation activities. A few companies not involved in the current partnership activities have also been approached. Description of the categories of actors interviewed is made in the next section.

The potential interviewees were contacted by email invitations that included the explanation of the context of the assignment, letter of support from the EC and the interview guide with a list of topics and relevant questions to be discussed (provided in the annex report). The interview guide (referred as the questionnaire) contained 50 questions divided by sections mentioned above.

The interviewees were given a freedom to use the interview as a guidance for the interview discussions and not forced to address all questions and topics presented here. In many cases the interview was organised by topical sections, in a few cases interviewees structurally followed question by question in providing their answers. Some interviewees preferred to provide written answers to the questionnaire. Finally, the interviewees were guaranteed their anonymity.

Overview of respondents to the targeted consultation

In total, 63 interviews have been conducted. However, that number does not correspond to the actual number of individuals interviewed since group interviews were also conducted with actors belonging from the same stakeholder category.

Moreover, situations were found where actors were belonging to several stakeholder categories, i.e. actors managing a BBI JU Flagship project could also be present in the BBI JU Team and Governing Board category. To avoid duplicates, such situations were resolved by allocating the individuals to their “main” category. That means that from one single interview, multiple visions and experiences could be collected⁶.

In total, 14 stakeholders categories were established as follow:

- The European Commission
- Member States with a bioeconomy strategy
- Member States without a bioeconomy strategy
- Regions
- BBI JU Team and Governing Board
- BBI JU Flagship
- BBI JU Other projects
- Companies BBI JU related
- Companies not BBI JU related
- Other Initiatives
- Business and industry associations
- NGOs and consumer associations
- Research and RTOs
- Experts

Key results/messages from the targeted consultation

The main findings of the interviews have been described by sections. Some sections received less input than others since they were more technical and required specific knowledge on the subject, which some actors did not have to provide relevant answers. Some sections received more input, such as the “objectives” section, which proved successful in generating enthusiasm and opinions from the interviewees and did not require technical knowledge.

Objectives

In general, interviewees were agreeing with the objectives of the future initiative, however, many of them stipulated that in the future initiative, the objectives should be more focused, and the scope should be enlarged to be more open to more sectors (e.g. waste management, food, soil etc.) and cover value chains that have not been covered before, such as for example plant based proteins. More emphasis should also be put on the circularity and on the environmental sustainability aspect of the objectives, as well as on the socio-economic aspect including the creation of jobs and growth, especially in rural areas and remote and economically vulnerable regions. Some interviewees suggested to link the objectives with the SDGs and to take a more regional perspective in that regard.

Creating a market for the bio-based economy and bringing products to commercialization were objectives often suggested by many stakeholders coming from different categories. In that path, a higher focus on improving the competitiveness of the EU industry was mentioned.

⁶ For further details on distribution statistics, see also the supporting study by Technopolis (2020).

According to the majority of the interviewees such objectives should be set and defined upfront, with a degree of flexibility, by the European Commission and the industry in a collaborative manner. A few interviewees suggested to leave that role for the European Commission only or for the industry only. However, many stakeholders suggested to involve more actors in the process such as primary producers, farmers, universities, member states, public and local authorities, regions, small cooperatives and SMEs. The importance of the role (consultative or full decision-making power) of each actor mentioned depended on the type of stakeholder category interviewed. Nonetheless, a point of agreement was found on having a balance between all actors in order to not have smaller actors eclipsed by the bigger ones. Such a balance was also mentioned when addressing the TRL levels that should be emphasized: some respondents said that the initiative should not exclude any TRL levels and have a balance of focus, while others said to focus mostly on higher TRL projects as they can bring impact much faster than the lower TRL projects. Yet, others suggested to focus mostly on lower TRL levels in order to not impede innovation. Another suggestion was made on involving the public and the consumers and informing them better about the bio-based economy and bio-based products. This consideration was generally linked to creating a market for bio-based products and related objectives.

Arguments regarding the different options varied greatly among the different stakeholder categories and can be exposed as such:

- A CPP is considered lighter, more flexible and as giving more influence to the EC. However, as it is less dependent on industry contributions and not requiring legally binding commitment, it also might generate less engagement with stakeholders and make it more difficult to stimulate industry who consider that the EC has too much say. Moreover, some consider that CPP will not allow long-term projections and will not have balanced representation of various TRLs in the overall project portfolio of the initiative.
- A CFP is depicted as problematic since it does not envisage involvement of the private sector in the initiative. Nonetheless, member states would have more weight which is considered as benefiting for some but creates the drawback of focusing too much on academic topics of research, therefore not sufficiently promoting innovations close to market and reflect industry needs.
- An IPP has been described as administratively more regulated and therefore less flexible in governance and other rules, difficult to steer and less inclusive/largely industry driven in the decision-making on the content of the work programme. However, it is considered very efficient in structuring very diverse sectors around bio-based value chains and bio-economy, as well as being the best option to cross the valley of death, boost the bio-economy and bring products to the market. The IPP is said to generate a higher engagement and commitment of industry (however many mentioned that the rules about commitments should focus on project level contributions and rather than on the programme level in order to secure industries interest and commitment), allows collaboration with other sectors and serves as a bridge between private actors and the EC. This option has a long-term approach and gives the predictability needed.

Some participants also explained that changing the structure of the potential initiative would create negative impacts and would lose the impetus. A statement often expressed is to have an improved version of the BBI JU, isolated suggestions for a “hybrid model” that would combine the flexibility of CPP and a strong back office/secretariat team from the IPP model.

Regarding the definition of the target groups, the panel agreed on having flexibility on the coverage of the target groups while keeping a degree of stability to ensure the sufficient involvement of actors. However, the interviewees suggested to include more stakeholders of the bio-economy in the future

initiative; therefore expressing a need to redefine the target group coverage. Groups that have been the most mentioned were SMEs, regional and local authorities, biomass producers and primary producers, members states, universities, academia, NGOs, citizens and consumers.

The majority of the interviewees expressed an interest to have open calls instead of closed calls to ensure innovation and competitiveness. However, suggestions have been made to have more focused calls and have calls only for small-size actors such as SMEs, who should also have a special status. Only a few suggested foreseeing a priority in the calls for the members, which implies to have a differentiation between members and non-members. Some stakeholders also expressed the need to have earmarked funding for Eastern and Central Europe countries.

Regarding the engagement on research priorities, different views were voiced. A lot of the interviewees suggested to involve more actors such as SMEs, NGOs, universities and regional and local actors in the advisory board. Some suggested having academia and industry leading the research priorities, others found it to be the role of the industry with the involvement of member states in order to align on national strategies. Others expressed an interest in including brand owners in the initiative, to get a close-to-market perspective and focus.

Regarding the different options for the future initiative, it has been expressed that CPP would be better suited for member states who would have a bigger influence, on the other hand CPP is depicted as not attractive for non-traditional bio-economy sectors who would not engage. However, IPP has been described as having more capacity to involve and represent more actors.

Roles and activities

An argument that has been expressed by many interviewees was to have a common understanding of the initiative, to have a clear methodology and definitions set beforehand. However, a clear interest has been expressed toward keeping a certain flexibility in the definition of the role and activities of the initiative, while stability was also considered a necessity.

The proposed role and activities were globally approved by the majority of the interviewees, nonetheless, updating the objectives and expanding the scope of the activities was a clear requested. It was suggested to have activities addressing new technologies in the annual work programme, to promote technology transfer and dissemination, establish network and awareness raising activities, create more and more ambitious CSA and be more involved in smaller entrepreneurial actions. Moreover, more administrative activities were suggested such as establishing a control mechanism and a follow-up board.

Regarding the different options for the future initiative, CPP has been described to have the potential to allow evolving objectives and activities, while the IPP has been considered as too rigid in this respect. However, the was found to IPP generate more visibility and has a dedicated service for activities.

Leverage effect

The subject of the leverage effect has sparked a lot of different opinions and views. Among them an agreement has been found on the difficulties to generate in-cash contributions either from the big industries or from the smaller industries. For the big industries, it has been considered impossible and delusional to get them to contribute to a “common pot” without them knowing in advance what they will get in return for their contribution. This has been described as “paying for the competition”. The same perspective was applied to the smaller actors, with the situation being even more complex as they often do not have the financial means. In-cash contributions have therefore been described as difficult. However, some expressed that in-cash was required from industries since the in-kind contribution is a way of circumventing co-financing. Others expressed that both contributions should be requested. Nonetheless, the commitment of industry was considered a necessity.

It has also been mentioned that the EC should be defining the requirements of contributions, and do it in advance. Moreover, some interviewees voiced that the commitment from companies depends on the commitment of the EC: the stronger the commitment of the EC, the stronger the commitment from companies. Another way considered to increase the leverage effect is to focus on high TRL projects, or on mid to later stages projects.

The IPP has been considered better placed to increase the leverage effect as it involves stable partners and has the potential to build momentum.

Coordination, structuring and mobilisation

It has been agreed among the panel that the coordination between and across sectors is important and required for the bio-based industry. It makes sense to mobilize and coordinate actors such as smaller stakeholders, SMEs, primary producers, regions, local authorities, member states, academia, end users, brand owners etc.

It has been mentioned that the IPP might be the best option to achieve the coordination, structuring and mobilisation objectives as this option is able to inform, mobilize primary sectors, create robustness of value chains and thus, generate cooperation across sectors. However, others stipulated that the coordination with academia should be done by Horizon Europe and not by the initiative. It has also been mentioned that the structuring effect requires cooperation with the policy level to be fostered. Added to that, since structures already exist within the current partnership, a continuation should be envisaged.

KPIs

Regarding the KPIs, a lot of suggestions have been made by the interviewees to include more and broader topics. First of all, it has been suggested to define the KPIs in advance and establish a more thorough definition, as the KPIs are sometimes too abstract and not easily translatable. In addition, a clearer method to assess the KPIs was requested. Then, a qualitative approach instead of a quantitative approach was described as more suited for the KPIs.

Regarding the subjects in particular, among the suggestions made, one could find to better link the KPIs with the SDGs, to have KPIs related to climate, to sustainability, to regional participation, to jobs, growth etc. It was also mentioned to link the KPIs with the number of flagships, with the products arriving on the market, with the commercialised technologies, with new value chains etc.

Costs and benefits

Regarding the costs and benefits, the CPP option has been described as cheaper and lighter than the IPP option. However, in the CPP the costs of development are deferred, so it might be that the costs of CPP and IPP will be the same when considering all costs. Moreover, it appears that CPP is too subjective on contributions, which is not the case in the IPP. Indeed, as the commitment of industry is considered as required and crucial, it should be ensured through legally binding commitment. In addition, an IPP appears to give the predictability needed, pairing with the opinion of a lot of interviewees stipulating that long-term funding is required for the initiative. In that regard, an issue pointed out was the lack of continuity, which led some interviewees to stipulate that follow up of investments is more important than financial contribution itself. Thus, a proper monitoring system has been suggested.

On the other hand, it has been advised to reduce bureaucracy, simplify reporting, achieve more with the same amount of contributions and creating a lighter structure of organization.

Need for Circular bio-based Europe

Regarding the timeframe of the EU partnership on Circular bio-based Europe, an agreement has been found among the panel for a long-term period, going from 7 to 10 years to sometimes as long as possible. Others suggested that it should match the financial framework, or to stop the initiative when it is not contributing to EU policy anymore.

A clear need towards the future initiative has been expressed by the majority of the interviewees. Without an initiative, investments in bio-based industry might happen outside the EU, therefore not ensuring EU's competitiveness. Moreover, the development of the industry might be much slower and the cooperation between different actors and sectors might not happen.

According to the panel, an initiative is needed to provide support, to encourage the intersectoral and value chain cooperation, to deliver EC's objectives, to promote social and sustainable ideas and support eco-innovation. In addition, the partnership is considered as having a facilitating role in the bio-based industry.

Research needs

Concerning the research needs and the process for setting priority research topics, different views have been expressed. The first view mentioned that the EC should be the main actor to set the agenda, a second view suggested to have the EC deciding in collaboration with industry. However, the role of the industry in this collaboration varied from a full collaboration to only being heard by the EC. A third view suggested to have the private sector to lead the research agenda and controlled by the university. Others said that there should be a balance between the actors, which led the interviewees to suggest involving more stakeholder in the process of setting up the research priorities such as primary producers, the EU13 countries, to engage more the SRG and the scientific committee.

In addition, the topics of the research priorities have been subject to some improvements to be closer to market, to focus on higher value products and commercialisation and on higher TRL projects. Nonetheless, it has been mentioned that the research agenda should come from the need to achieve environmental targets of the EC and address the societal challenges as well.

Contribution to EU policies

The future initiative might be contributing to the EU policy objectives by promoting and raising awareness about the bio-based industry, promoting existing standards or labels but also by de-risking investment and filling the funding gap in the industry. In that regard, the future initiative needs to accompany the industry and producers in promoting bio-based products. It might also accelerate the market uptake of solutions to contribute to the EU policy objectives by collaborating with and involving smaller stakeholders such as SMEs and consumers.

It has been recognised that policy had to change and that it is benefiting to have projects followed up by policies measures. It has been considered crucial to monitor how the future initiative will be contributing to EU policies objectives.

Regarding the options of the future initiative, an IPP is considered suited to promote and raise awareness, however it is less flexible and it has been mentioned that the EC has minor access to information. CPP has been considered easier by few interviewees.

Governance/organisation

Regarding the governance of the future initiative, it was suggested to involve many new actors. Member states, as a potential actor, have been sparking the most diverging opinions; some interviewees said member states should be involved others were opposing their involvement since if they do not speak with one voice it would create confusion, others suggested to communicate with them instead of involving them closely. In addition, universities, academia and research institutes were mentioned as actors to be included, as well as public services who should get a better representation.

Interviewees urged to give SMEs a better representation and participation which might be best guaranteed by the IPP. It has been also advised to look at the possibilities for regions to participate.

Openness and flexibility, according to the panel, should be secured for new key actors, member states, partners and target groups. For example, a flexibility for smaller actors in terms of time should be accorded. However, in some instances the inclusion of international actors in the initiative was not deemed appropriate..

Collaboration with other initiatives

Collaboration with other initiatives has been described as important but sometimes difficult. Collaboration might scale out synergies and might be optimising efforts through synergies, which is considered as important. Collaboration with national and regional levels has been suggested, however collaboration with international level sparked less enthusiasm as it is harder even if considered valuable since it can bring technologies from the outside to the EU.

Collaboration with NGOs, smaller developers, brands, agri business and citizens has been mentioned as having a role to play. Establishing links with other public and private partnerships were suggested to cover potential overlaps, and collaboration with initiative like CAP, SPIRE and others have also been described to be beneficial.

Benefits of EU action

According to the panel, an EU initiative is needed for the bio-based industry since the industry is considered too young to develop by itself. In addition, the EU initiative has a structuring effect and is thus needed to drive and coordinate multiple stakeholders. The following arguments on the necessity to have an EU initiative were put forward; bridging the valley of death, de-risking, advances on R&D, bringing incentives to operate in the EU, ensuring EU's competitiveness etc.

In that regard, some have expressed the need for an IPP, while others said that CPP might be too light to ensure the objectives and overcome the potential barriers.

1.3.4. Open Public Consultation

APPROACH TO THE OPEN PUBLIC CONSULTATION

The consultation was open to everyone via the EU Survey online system⁷. The survey contained two main parts and an introductory identification section. The two main parts collected responses on general issues related to European partnerships (in Part 1) and specific responses related to 1 or more of the 12 candidate initiatives (as selected by a participant).

The survey contained open and closed questions. Closed questions were either multiple choice questions or matrix questions that offered a single choice per line, on a Likert-scale. Open questions were asked to clarify individual choices.

The survey was open from 11 September till 12 November 2019. The consultation was available in English, German and French. It was advertised widely through the European Commission's online channels as well as via various stakeholder organisations.

The analysis of the responses was conducted by applying descriptive statistic methods to the answers of the closed questions and text analysis techniques to analyse the answers of the open questions. The

⁷ <https://ec.europa.eu/eusurvey/runner/ConsultationPartnershipsHorizonEurope>

keyword diagrams in this report have been created by applying the following methodology: First, the open answer questions were translated into English. This was followed by cleaning of answers that did not contain relevant information, such as “NA”, “None”, “no comment”, “not applicable”, “nothing specific”, “cannot think of any”, etc. In a third step, common misspellings were corrected, such as “excellence” instead of “excellence”, or “partnership” instead of “partnership”. Then, the raw open answers were tokenised (i.e. split into words), tagged into parts of speech (i.e. categorised as a noun, adjective, preposition, etc.) and lemmatised (i.e. extraction of the root of each word) with a pre-trained annotation model in the English language. At this point, the second phase of manual data cleaning and correction of the automatic categorisation of words into parts of speech was performed. Finally, the frequency of appearance and co-occurrences of words and phrases were computed across the dataset and the different sub-sets (e.g. partnerships, stakeholder groups). Data visualisations were created based on that output.

The keyword graphs in the following sections have been built based on the relationships between words in the open responses of the survey participants. It features words that appear in the same answer either one after the other or with a maximum distance of two words between them. Each keyword is represented as a node and each co-occurrence of a pair of words is represented as a link. The size of the nodes and the thickness of the links vary according to the number of times that keywords are mentioned and their co-occurrence, respectively. In order to facilitate the visualisation of the network, the keyword graphs have been filtered to show the 50 most common co-occurrences. Although the keywords do not aim to substitute a qualitative analysis, they assist the identification of the most important topics covered in the answers and their most important connections with other topics, for later inspection in the set of raw qualitative answers.

1.3.5. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Setting joint long-term agendas

Respondents were asked how relevant the involvement of actors is in setting joint long-term agenda to ensure that the proposed European Partnership would meet its objectives (see Figure 23). The highest amount of respondents indicated that the involvement of Industry is ‘very relevant’. A large part of respondents also indicated that the involvement of Academia and Member States and Associated Countries is ‘very relevant’. The answers are more evenly split with regard to Foundations and NGOs and Other stakeholders.

Academic/research institution, as well as EU citizen and public authorities indicated that the involvement of Industry and Academia are ‘very relevant’ followed by Member States and Associated Countries and Foundations and NGOs as the second choice. Business association indicated that the involvement of Industry and Member States, Associated Countries and Academia is the most relevant, however Foundations and NGOs in turn is the least important. SMEs and businesses (250+) indicated similar preferences in the OPC, where the involvement of Industry and Member States and Associated Countries is the most relevant, the least relevant is involvement of Foundations and NGOs. NGOs think that the engagement of Industry and Foundations and NGOs will contribute the most.

Figure 23: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives? - Responses for the Circular Bio-based Europe Initiative - Setting joint long-term agenda with strong involvement of

Figure 24: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives? - Responses for the Circular Bio-based Europe Initiative - Setting joint long-term agenda by stakeholder type with strong involvement of

Pooling and leveraging resources through coordination, alignment and integration with stakeholders

With respect to the relevance of coordination, alignment or integration with specific stakeholders' groups in pooling and leveraging resources, such as financial, infrastructure, in-kind expertise etc., to meet Partnership objectives, the patterns are very similar. More than two third of respondents in all stakeholder groups indicated that industry was very relevant. Member States and Associated Countries were very relevant for business associations, Academic/research institution, EU citizen and Public authority.

With regard to Academia the least of respondents felt that they were very relevant. However, Academic/research institution, EU citizen and Public authority consider this element as relevant. Most of the respondents among different stakeholder groups did not indicate Foundations and NGOs as very relevant. No respondents from different stakeholder groups indicated that any of the categories was

‘Not relevant at all’. No statistical differences were found between the views of citizens and other respondents.

Figure 25: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Responses for the Circular Bio-based Europe Initiative - Pooling and leveraging resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with:

Relevance of the partnership composition

Respondents were asked about the relevance of the Partnership composition, such as the flexibility in the composition of partners over time and the involvement of a broad range of partners (including across disciplines and sectors), to reach Partnership objectives. As is visible in Figure 26, ensuring involvement of a broad range of partners has more ‘very relevant’ answers (132, 66.67%) than the flexibility in the composition of partners (96, 47.52%). Overall 80% of respondents have given flexibility either a score of 4 or 5 (very relevant), while 84% have given the broad range of partners a score of 4 or 5 (very relevant).

No statistical differences were found between the views of citizens and other respondents.

Figure 26: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Responses for the Circular Bio-based Europe Initiative - Partnership composition

Relevance of activities

Respondents were asked to provide opinions on the relevance of implementing a set of activities for meeting the objectives of the candidate Circular Bio-based Europe Partnership. Among activities were listed – a joint R&D programme, collaborative R&D projects, deployment and piloting activities, input to regulatory aspects and co-creation of solutions with end-users. Out of 203 respondents, 147 (72.41%) indicated that deployment and piloting activities are very relevant to ensure that the Partnership would meet its objectives. Collaborative R&I projects have also been considered as very relevant by a large number of respondents (120 respondents or 59.11%). In particular, a large majority of academics, business associations and EU citizens, and all respondents from public authorities, indicated collaborative R&I projects as relevant. In contrast, input to regulatory aspects is considered less relevant by respondents. However, still a large share of academics, business associations, businesses (250+), public authorities and other types of respondents indicated this element as relevant.

Respondents that are/were involved in a current/preceding partnership found joint R&I programmes more relevant than other respondents. Overall, this element was considered as relevant by more than half of business associations, business organisations and NGOs, and by more than two thirds of academics, EU citizens and public authorities.

Figure 27: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Responses for the Circular Bio-based Europe Initiative - Implementing the following activities

1.3.6. Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Respondents were also asked to assess the relevance of a specific legal structure (funding body) for the candidate European Partnership to implement several activities. According to Figure 28 most respondents indicated that a specific legal structure was ‘very relevant’ to implement its activities more effectively. The majority of stakeholders from business associations, SMEs, businesses (250+), public authorities and EU citizens indicated a high relevance of a legal structure for a more effective implementation of activities.

Respondents that are/were involved in a current/preceding partnership found the effective implementation of activities, increased financial leverage and the collaboration with other partnerships more relevant than other respondents.

Overall, the majority of respondents in all stakeholder groups indicated the set-up of a legal structure as relevant or highly relevant to: implement activities more effectively and more transparently; increase financial leverage; ensure better links to practitioners on the ground; obtain more buy-in and long-term commitments from other partners; ensure harmonization of standards; and facilitate synergies with other EU and national programmes.

A legal structure was considered relevant or highly relevant for a faster implementation of activities to respond to sudden market or policy needs by the majority of respondents in all stakeholder groups, with the exception of business associations where more than half considered it relevant to a smaller degree.

Contrarily to all other stakeholder groups, a moderate majority of EU citizens considered a legal structure either close to not relevant or relevant to a smaller degree to ensure better links to regulators. Similarly, the majority of NGOs indicated a specific legal structure to be close to not relevant or relevant only to a small degree to facilitate collaboration with other relevant European Partnerships.

The number of respondents that have indicated that they view a measure as ‘not relevant at all’ is very small across all the measures and all stakeholder groups.

Figure 28: In your view, how relevant is to set up a specific legal structure (funding body) for the candidate European Partnership to achieve the following? - Responses for the Circular Bio-based Europe Initiative

1.3.7. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Respondents were asked to assess the scope and coverage of the Circular Bio-based Europe Partnership, based on its inception impact assessment. The clear majority of the respondents across all stakeholder groups have indicated that the partnership has the right scope and coverage across all areas, although geographical coverage and types of partners covered have the highest number of right scope and coverage answers. On average, a very small share of respondents have indicated that they felt the scope and coverage were too broad, while a slightly higher but still small share of respondents have indicated that the scope was too narrow. In particular, a higher share of NGOs compared to other stakeholders groups, have indicated this with regards to technologies covered. Similarly, a higher share of academics compared to other stakeholder groups, have indicated geographical coverage, research areas, range of activities and sectoral coverage to be too narrow, although the majority still considered these as correctly covered.

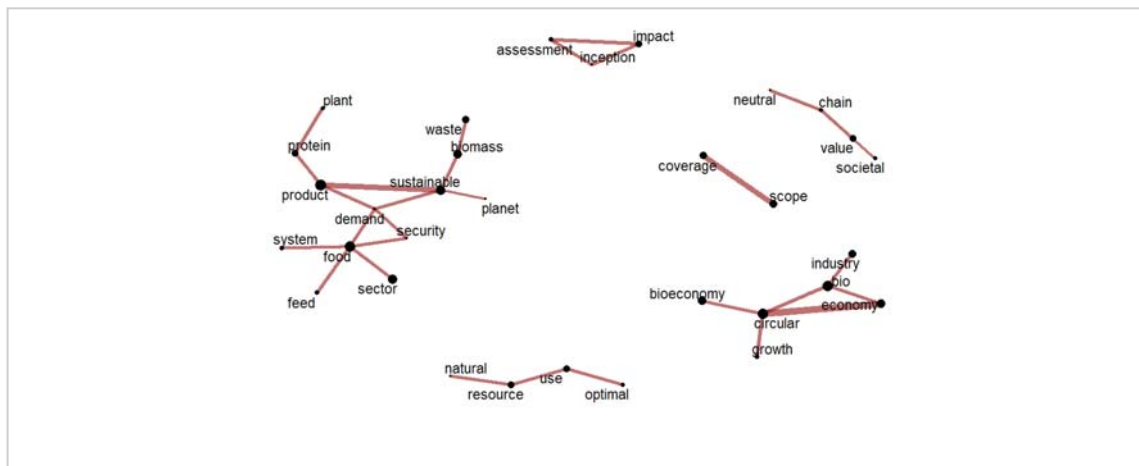

No statistical differences were found between the views of citizens and other respondents.

Figure 29: What is your view on the scope and coverage proposed for this candidate institutionalised European Partnership, based on its inception impact assessment? Respondents for the candidate Circular Bio-based Europe Partnership

Aside from this multiple-choice question, the respondents were also asked to provide any comment that they may have on the proposed scope and coverage for this candidate Institutionalised Partnership. The keyword analysis used for open questions resulted in the graph shown below. This analysis showed the respondents used this question to talk about sustainable biomass, plant protein, food security as well as the circular (bio)economy and an inception impact assessment.

Figure 30: Assessment of open answers with regard to the proposed scope and coverage for this candidate Institutionalised Partnership, 30 most common co-occurring keywords (N=69)

Two business respondents endorse the vision as it has been formulated by the BIC including food security & demand for sustainable products; sustainable planet; jobs and growth in the circular bioeconomy; and circular bioeconomic society. An EU citizen suggested additionally including the development of biomimetic materials for large-scale applications in the energy and construction sector. A representative of academia pointed out that the point of view of the citizens has to be considered. Another representative of academia emphasized that it is necessary to finance innovative technologies. A representative of a regional authority underlined that regional or bigger geographical coverage is needed in terms of volumes and market. A representative of a large company drew the attention to the significant potential coming from the Industrial Symbiosis.

1.3.8. *Scope for rationalisation and alignment of candidate European Partnerships with other initiatives*

The respondents were also asked if they thought it would be possible to rationalise the candidate European Institutionalised Partnership and its activities, and/or to better link it with other comparable initiatives. 100 respondents (57.47%) have indicated that they think this is the case.

No statistical differences were found between the views of citizens and other respondents.

The respondents who answered affirmatively were asked to indicate which other comparable initiatives this proposed partnership could be linked with. The keyword analysis used for open questions resulted in the graph shown in Figure 31. This analysis showed the respondents used this question to talk about several initiatives with which it should actively cooperate and foster links, including Innovative SMEs (suggested by a large company); the HEU missions on "Soil health and food" and on "Healthy Oceans, Seas, Coastal and Inland Waters" (suggested by an academic); and European Platforms such as SUSCHEM on plastic circular economy and the materials platform EUMAT (suggested by an academic). Making these links would ensure the initiative reaches its potential of significant environmental impact.

Figure 31: Assessment of open answers with regard to the proposed scope and coverage for this candidate Institutionalised Partnership, 30 most common co-occurring keywords (N=53)

For the respondents who answered negatively on the previous question, the results of the analysis resulted in the chart shown in Figure 32 showing the co-occurrences of keywords. The results show that respondents are interested in the uptake of bioeconomy and circular initiatives by the industry and having real impact comparable to other types of partnerships. Respondents acknowledged that the candidate partnership is the only initiative at EU level that specifically addresses the challenges of the biotechnology sector. A medium company underlined that the Institutionalized Partnership is necessary to enable shorter development and scale-up technologies; to bring new bio-based products to the market; and further strengthen EU's position in the global bio-economy market. A medium company acknowledged that while the bioeconomy will take place in regions, it requires a very broad stakeholder network to identify the relevant technologies and bring them to higher TRLs.

Figure 32: Assessment of open answers on the question why other comparable initiatives are not suitable to be linked, 30 most common co-occurring keywords (N=15)

1.3.9. Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Respondents were asked to assess the relevance of the candidate European Institutionalised Partnership to deliver on listed impacts. According to Figure 33, among societal impacts, a greater number of respondents suggest that the Partnership would be ‘very relevant’ for reducing greenhouse emissions, for maximisation of valorisation of organic waste, and agriculture and forestry residues, and for replacement of oil-based chemicals and materials with bio-based and biodegradable ones. In

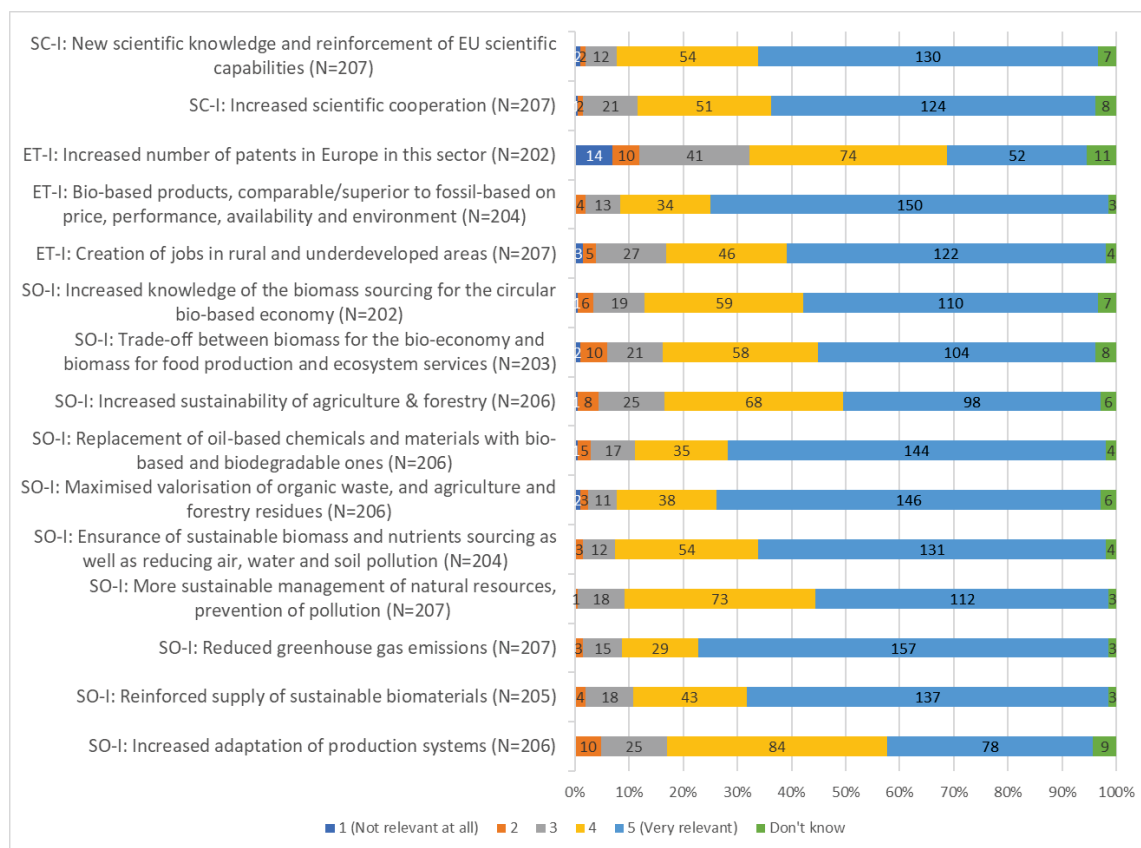

comparison, the least number of respondents considered that the partnership would be ‘very relevant’ for increasing adoption of production systems. Among economic/technological impact categories, a greater number of respondents (150 out of 204, or 73.53%) indicated that the Partnership would be ‘very relevant’ for delivery of bio-based products that are comparable and/or superior to fossil-based products. The pattern of responses on impacts in the area of science are very similar – over 60% of respondents believe that the Partnership would be ‘very relevant’ for generating new scientific knowledge and for increasing scientific cooperation.

The majority of respondents across all stakeholder groups considered European Partnerships to be either very relevant or relevant to deliver the targeted scientific, social and economic impacts. Citizens found the societal impact related to sustainable management of natural resources and the economic/technological impact related to the creation of jobs in rural and underdeveloped areas more relevant.

A greater share of businesses (250+), SMEs, public authorities and NGOs, compared to other stakeholder groups - although still not the majority - considered European Partnerships to be either not relevant or relevant to a smaller degree to deliver targeted social impacts.

An even higher share of the abovementioned stakeholder groups - although not the majority - considered European Partnerships to be either not relevant or relevant to a smaller degree to deliver targeted economic impacts.

Figure 33: In your view, how relevant is it for the candidate European Institutionalised Partnership to deliver on the following impacts? Responses for the candidate Circular Bio-based Europe Partnership

1.3.10. Summary of campaigns results for this specific initiative

One campaign has been identified among respondents that decided to provide views on the candidate Partnership on Circular Biobased Europe. This campaign consists of 20 respondents (campaign #5).

Table 6: Overview of responses of the first campaign (campaign #5) (N=20)

Question category	Summary of responses
Research and innovation problems	The answer category “lack of understanding of the circular and bio-based economy” was assessed ‘very relevant’ by all respondents. The other categories received a score of 4, on average.
Structural and resource problems	With exception of two respondents, all respondents gave a high score (5 ‘very relevant’) for a category “limited collaboration and pooling of resources between public actors and private actors etc.”. The other category received a lower score (between 3 and 4).
Problems in uptake of digital innovations	Most respondents considered that the following categories are ‘very relevant’: “lack of competitiveness with the traditional products/materials”, “lack of private investment”, “lack of public investment”. Other answer categories received a lower score, on average.
Preferred Horizon Europe intervention	Institutionalised Partnership option was selected by most respondents. Only one respondent indicated that the challenges can be better addressed via “co-funded

Question category	Summary of responses
	<p>partnership”.</p> <p>When respondents were asked to explain their choice, almost all of them used the following quote: <i>“Challenges mentioned above require joint investments, setting up new value chains and creating synergies. An iPPP addresses the multi-actor nature of the bio-based industries and enables long-term collaboration of different sectors (industry, academia, society, member states, regions) to solve these challenges and to create a favourable climate for investment in the bio-based sector in Europe”.</i></p>
Relevance of actors for setting joint long-term agenda	Almost all respondents consider that involvement of industry is ‘very relevant’. The involvement of “Member States and Associated Countries” is considered ‘relevant’ (score 4) by most respondents. Other categories received a slightly lower score, on average.
Relevance of actors for pooling and leveraging resources	Almost all respondents consider that involvement of industry is ‘very relevant’. The involvement of “Member States and Associated Countries” is considered ‘relevant’ (score 4) by most respondents. Other categories received a slightly lower score, on average.
Partnership composition	Most respondents suggest that “involvement of a broad range of partners, etc.” is ‘very relevant’. The second answer category received a lower score, on average.
Implementation of activities	Across all respondents consider that “deployment and piloting activities” are ‘very relevant’. Other answer categories were given a score of 4 ‘relevant’, on average.
Relevance of the legal structure	With exception of one respondent, all respondents consider that the legal structure would be ‘very relevant’ for implementing Partnership activities more effectively. Other answer categories received an average score of 4 ‘relevant’. The lowest score (namely, 3) was given to the category “implement activities faster to respond to sudden market or policy needs”.
Scope and coverage of the candidate Partnership	<p>Across all answer categories, most respondents consider that the elements are of right scope and coverage.</p> <p>Respondents were offered an opportunity to provide comments on the proposed scope and coverage of the Institutionalised Partnership. Most of them included the following quote:</p> <p><i>“Scope (cf. 2050 vision signed by BIC & 14 associations):</i></p> <ol style="list-style-type: none"> <i>1. Food security and demand for sustainable products (integrated, efficient production of food, feed, bio-based products, services, energy with minimal environmental impact)</i> <i>2. A sustainable planet (carbon-neutral value chains, optimal use of natural resources, protect environment, add societal value)</i> <i>3. Jobs & growth in the circular bioeconomy (mobilise local feedstock)</i> <i>4. Circular bioeconomic society (participating citizens).”</i>
Rationalisation of the candidate Partnership and linking to other initiatives	<p>90% of respondents (18 out of 20) consider that it would not be possible to rationalise the candidate Partnership and its activities, and/or to better link it with other comparable initiatives.</p> <p>Respondents were asked to explain their answer, most of them inserted a following quote: <i>“There is no similar instrument to address the challenges for the bio-based sector in the EU like an iPPP: it covers a funding gap, enables scaling up and shorter time to market through focus on higher TRL (5-8), provides grants (vis a vis loans and which don’t have the same effect), bio-based industry sector is still very fragmented</i></p>

Question category	Summary of responses
	<i>between actors and across geographies, essential to continue on-going structuration.”</i>
Societal impact	Almost all respondents consider that the Partnership would be ‘very relevant’ to deliver on most categories of results. The exceptions include: “increased adaptation of production systems”, “more sustainable management of natural resources, prevention of pollution”, “increased sustainability of agriculture & forestry” and “increased knowledge of the biomass sourcing for the circular bio-based economy”. In those categories, the average score is 4 ‘relevant’.
Economic/technological impact	For the categories “creation of jobs in rural and underdeveloped areas” and “increased number of patents in Europe in this sector”, majority of respondents indicated that impacts are ‘very relevant’. The remaining answer category received a score of 4, on average.
Scientific impact	Across all listed categories, majority of respondents indicated that impacts are ‘very relevant’.

Annex 3

Who Is Affected And How?

1. PRACTICAL IMPLICATIONS OF THE INITIATIVE

- The proposed institutionalised partnership enables participation of all key stakeholders potentially contributing to the specifications and delivery of the strategic R&I agenda through a clearly defined membership structure. The stakeholders concerned are specified in the table below.
- It provides a forum for co-drafting R&I priorities and the work programmes, ensuring that they are aligned with industry and market needs.
- Participation is less flexible than under other options, but it is nevertheless possible to change the profile of participation over time, with new partners joining to support new areas of activity in response to emerging results and changing priorities.

SUMMARY OF COSTS AND BENEFITS

<i>I. Overview of Benefits (total for all provisions) – Preferred Option</i>		
<i>Description</i>	<i>Estimation (quantitative or qualitative)</i>	<i>Comments</i>
<i>Direct benefits</i>		
A more competitive primary sector producing biomass		Higher and secure income for primary producers (also in less-favoured regions); secured supply for bio-based industries; economic growth for SMEs.
Cost savings for municipalities and regions regarding waste disposal		Part of the biowaste sold to the bio-based industry as raw material
A more competitive bio-based industry sector		Secured biomass supply for bio-based industries; economic growth for SMEs.
Access to more sustainable products by brand-owners and consumers		Continuously increasing demand satisfied
<i>Indirect benefits</i>		
Reduction of CO ₂ emissions due the switch from fossil- to bio-based		A larger proportion of chemicals and materials including plastics produced from biomass and biowaste.

Biodiversity conservation or enhancement		As a result of lower toxicity bio-based products developed and as a result of sustainable management of natural resources, especially biodiversity-friendly biomass generation.
--	--	---

(1) Estimates are relative to the baseline for the preferred option as a whole (i.e. the impact of individual actions/obligations of the preferred option are aggregated together); (2) Please indicate which stakeholder group is the main recipient of the benefit in the comment section;(3) For reductions in regulatory costs, please describe details as to how the saving arises (e.g. reductions in compliance costs, administrative costs, regulatory charges, enforcement costs, etc.; see section 6 of the attached guidance).

II. Overview of direct and indirect costs – Preferred option							
		Citizens/Consumers		Businesses ⁽⁸⁾		Administrations ⁽⁹⁾	
		One-off	Recurrent	One-off	Recurrent	One-off	Recurrent
Management/ Administrative costs	Direct costs				€ 1 m per year over 10 years ⁽¹⁰⁾		€ 1 m per year over 10 years ⁽¹⁰⁾
	Indirect costs						
Personnel costs	Direct costs				€ 1.25 m per year over 10 years (for 25 FTE) ⁽¹¹⁾		€ 1.25 m per year over 10 years (for 25 FTE) ⁽¹¹⁾
					€ 0.4 m per year over 11 years for 4 FTE ⁽¹²⁾		
	Indirect costs						€ 0.5 m per year over 11 years for 5 FTE at operational and coordinating Commission

⁸ Sum of below: 10+12.5+4.4 = EUR 26.9 m.

⁹ Sum of below: 10+12.5+5.5 = EUR 28 m.

¹⁰ Other expenses and finance costs of the BBI JU programme office were EUR 2.1 m in 2018 (Accounts 2018, p.8), to be paid 50:50 by the EC and the private partner.

¹¹ BBI JU programme office staff cost with 20 staff was EUR 2 m in 2018 (Accounts 2018, p. 8). Extrapolation to 25 staff in CBE. To be paid 50:50 by the EC and the private partner.

¹² The private partner's secretariat. Estimation.

							units
Coordination costs (or transaction costs)							
Budget expenditure/ investment costs				€ 1,000 to 3,000 m over the whole period ⁽¹³⁾		€ 1,000 m over the whole period ⁽¹⁴⁾	

(1) Estimates to be provided with respect to the baseline; (2) costs are provided for each identifiable action/obligation of the preferred option otherwise for all retained options when no preferred option is specified; (3) If relevant and available, please present information on costs according to the standard typology of costs (compliance costs, regulatory charges, hassle costs, administrative costs, enforcement costs, indirect costs; see section 6 of the attached guidance).

¹³ 100-300% private contribution (also pending MFF decision and breakdown of the budget). No contribution commitment from private partner yet.

¹⁴ Pending MFF decision and breakdown of the budget.

Annex 4 Analytical Methods

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines¹⁵ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This is complemented by integrating the **conditions and selection criteria for European Partnerships**, as well as requirements for setting up Institutionalised Partnerships.¹⁶

1. OVERVIEW OF THE METHODOLOGIES EMPLOYED

In terms of **methods and evidence used**, the set of impact assessments for all candidate Institutionalised European Partnerships draw on an external study covering all initiatives in parallel to ensure a high level of coherence and comparability of analysis.¹⁷ (

All impact assessments mobilised a mix of qualitative and quantitative data collection and analysis methods. These methods range from desk research and interviews to the analysis of the responses to the Open Consultation, stakeholder analysis and composition/portfolio analysis, bibliometrics/patent analysis and social network analysis, and a cost-effectiveness analysis.

The first step in the impact assessment studies consisted in the definition of the context and the problems that the candidate partnerships are expected to solve in the medium term or long run. The main data source in this respect was desk research. This includes grey and academic literature to identify the main challenges in the scientific and technologic fields and in the economic sectors relevant for the candidate partnerships, as well as the review of official documentations on the policy context for each initiative.

In the assessment of the problems to address, the lessons to be learned from past and ongoing partnerships were taken into account, especially from relevant midterm or ex-post evaluations.

The description of the context of the candidate institutionalised European Partnerships required a good understanding of the corresponding research and innovation systems and their outputs already measured. Data on past and ongoing Horizon 2020 projects, including the ones implemented through Partnerships, served as basis for descriptive statistic of the numbers of projects and their respective levels of funding, the type of organisations participating (e.g. universities, RTOs, large enterprises, SMEs, public administrations, NGOs, etc.) and how the funding was distributed across them. Special attention was given to analysing the participating countries (and groups of countries, such as EU, Associated Countries, EU13 or EU15) and industrial sectors, where relevant. The sectoral analysis required enriching the eCORDA data received from the European Commission services with sector information extracted from ORBIS, using the NACE codification up to level 2. These

¹⁵ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

¹⁶ A pivotal element of the present analysis is the so-called two-step ‘necessity test’ for European Partnerships, used to establish: step 1) the need for a partnership approach in the first place, followed by step 2) a justification for the form of Institutionalised Partnership. The necessity test is described in Annex 6. This impact assessment focuses on the second step of the test.

¹⁷ Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe

data enabled the identification of the main and, where possible, emerging actors in the relevant systems, i.e. the organisations, countries and sectors that would need to be involved (further) in a new initiative.

A Social Network Analysis was performed by the contractors using the same data. It consisted in mapping the collaboration between the participants in the projects funded under the ongoing R&I partnerships. This analysis revealed which actors – broken down per type of stakeholders or per industrial sector – collaborate the most often together, and those that are therefore the most central to the relevant research and innovation systems.

The data provided finally served a bibliometric analysis run by the contractor aimed at measuring the outputs (patents and scientific publications) of the currently EU-funded research and innovation projects. A complementary analysis of the Scopus data enabled to determine the position and excellence of the European Union on the international scene, and identify who its main competitors are, and whether the European research and innovation is leading, following or lagging behind.

A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options.

The conclusions drawn from the data analysis were confronted to the views of experts and stakeholders collected via three means:

- The comments to the inception impact assessments of the individual candidate institutionalised European Partnerships;
- The open public consultation organised by the European Commission from September to November 2019;
- The interviews (up to 50) conducted by each impact assessment study team conducted between August 2019 and January 2020 (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others).

The views of stakeholders (and experts) were particularly important for determining the basic functionalities (see further below) that the future partnerships need to demonstrate to achieve their objectives as well as their most anticipated scientific, economic and technological, and societal impacts. The interviews allowed more flexibility to ask the respondents to reflect about the different types of European Partnerships. Furthermore, as a method for targeted consultation, it was used to get insights from the actors that both the Study Teams and the European Commission were deemed the most relevant. For the comparative assessment of impacts, the external contractors confronted the outcomes of the different stakeholder consultation exercises to each other with a view of increasing the validity of their conclusions, in line with the principles of triangulation.

Annex 2 includes also the main outcomes of the stakeholder consultation exercises.

2. METHOD FOR ASSESSING THE EFFECTIVENESS, EFFICIENCY AND COHERENCE OF EACH OPTION - THE USE OF FUNCTIONALITIES

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has been adapted to introduce “**functionalities**”. These are used to reflect *what is needed in terms of implementation* for each candidate initiative to be able to deliver on its objectives. The functionalities are the **distinguishing factors** between the different options and are directly linked to the European Partnerships’ selection criteria of openness and transparency, additionality and directionality (see Annex 6). Based on the objectives identified and the targeted impact, functionalities describe what this requires in terms of implementation. Each form of implementation is then assessed to establish to which degree it would allow for these functionalities to be covered, e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of stakeholders’ R&I strategies¹⁸; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with other EU, national or regional policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options and allows a structured comparison of the options against the selection criteria for European Partnerships.

Figure 3 Overview of key functionalities of each form of implementation of European Partnerships

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
Type and composition of actors (including openness and roles)				
<u>Partners:</u> N.A., no common set of actors that engage in planning and implementation <u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> core of national funding bodies or governmental research organisations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> limited, according to national rules of partner countries	<u>Partners:</u> National funding bodies or governmental research organisation <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations

<u>Activities:</u> Horizon Europe standards that allow broad range of individual	<u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions,	<u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to

¹⁸ The criterion on the ex-ante demonstration of partners’ long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
actions <u>Additionality:</u> no additional activities and investments outside the funded projects <u>Limitations:</u> No systemic approach beyond individual actions	support to market, regulatory or policy/ societal uptake <u>Additionality:</u> Activities/investments of partners, National funding <u>Limitations:</u> Limited systemic approach beyond individual actions.	rules, support to regulatory or policy/ societal uptake <u>Additionality:</u> National funding <u>Limitations:</u> Scale and scope depend on the participating programmes, often smaller in scale	or policy/societal uptake, possibility to systemic approach <u>Additionality:</u> National funding	regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds). <u>Additionality:</u> Activities/investments of partners/ national funding
Directionality				
<u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years. <u>Limitations:</u> Fully taking into account existing or to be developed SRIA/ roadmap	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Input to FP annual work programme drafted by partners, finalised by COM (comitology) Objectives and commitments are set in the contractual arrangement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the Grant Agreement.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM Objectives and commitments are set in the legal base.	<u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution Annual work programme drafted by partners, approved by COM (veto-right in governance) Objectives and commitments are set in the legal base.
Coherence: internal (Horizon Europe) and external (other Union programmes, national programmes, industrial strategies)				
<u>Internal:</u> Between different parts of the Annual Work programme can be ensured by COM <u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Limited synergies with other Union programmes and industrial strategies If MS participate, with national/ regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/ regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with national/ regional programmes and activities	<u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM <u>External:</u> Synergies with other Union programmes and industrial strategies If MS participate, with national/ regional programmes and activities

On the basis of the evidence collected, the thematic impact assessments evaluate the **effectiveness** of the various policy options along three dimensions corresponding to the

different categories of likely impacts: scientific, economic and technological, and societal (including environmental). Each impact assessment considers to which extent the different policy options fulfil the desirable ‘functionalities’ and are therefore likely to produce the targeted impacts. In addition, where specific impacts (e.g. on fundamental rights) are relevant for a candidate Partnership, these are assessed in the corresponding report and according to the Better Regulation Guidelines and Toolbox. This analysis results in a scoring of the policy options with a three-point scale. Scores vary from + to +++, where + refers to low potential for reaching the likely impacts, ++ to a good potential, and +++ to a high potential. The effectiveness assessment of the different options does not use a compound score but concludes on as many scores as there are expected impacts. This is done to increase transparency and accuracy in the assessment of options. Qualitative and quantitative evidence is provided to motivate each score.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence corresponds to the consistency between a given implementation mode and the other actions under Horizon Europe. External coherence refers instead to the alignment with other initiatives at EU, national and international level beyond Horizon Europe that are relevant to a thematic area. Each option (implementation mode) is assessed following a three-point qualitative scale.

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach¹⁹ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account²⁰. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs of each candidate initiative.²¹ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the

¹⁹ For further details, see Better Regulation Toolbox # 57.

²⁰ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

²¹ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

overall investment).

- For a Co-Programmed partnership the costs of preparation and implementation increase only marginally compared to the baseline (<1%),²² but lead to an additional R&I investment of at least the same amount than the Union contribution²³ (efficiency of 98% for the overall investment).
- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2,3 times the Union contribution²⁴. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).²⁵
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution²⁶. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution²⁷. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0		↑↑		
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0		↑↑		
Ex-ante Impact Assessment for partnership		0		↑↑↑	
Preparation of EC proposal and negotiation		0		↑↑↑	
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0		↑		

²² Specifically, some additional set-up costs linked for example to the creation of a strategic research and innovation agenda (SRIA) and additional running costs linked with the partners role in the creation of the annual work programmes and the Commission's additional supervisory responsibilities. A CPP will have lower overall costs than each of the other types of European Partnership, as it will function with a smaller governance and implementation structure than will be required for a Co-Funded Partnership or an Institutionalised Partnership and – related to this – its calls will be operated through the existing HEU agencies and RDI infrastructure and systems.

²³ Minimum contributions from partners equal to the Union contribution.

²⁴ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

²⁵ These costs reflect set-up costs and additional running costs for partners, and the Commission, of the distributed, multi-agency implementation model.

²⁶ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

²⁷ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC	0				↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**). In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

3. METHOD FOR IDENTIFYING THE PREFERRED OPTION – THE SCORECARD ANALYSIS

For the **identification of the preferred option**, the scorecard analysis builds a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a value of 1 to 3, scoring the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.²⁸ The scorecard analysis was used to highlight those options that stand out as not being dominated by any of the other options in the group: such options are then retained as the preferential ones in the remainder of the analysis. It also allowed for easy visualisation of the pros and cons of alternative options.

Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (cost-effectiveness). In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

These costs essentially refer to the administrative, operational and coordination costs of the various options. The figure shows how the scoring of costs range from a value of 0, in case an option does not entail any additional costs compared to the baseline (traditional calls), to a score of (-) for options introducing limited additional costs relative to the baseline and a score

²⁸ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

of (- -) when substantial additional costs are expected in comparison with the baseline. Should the costs of a policy option be lower than those of the baseline, (+) and (+ +) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. A score of + is therefore assigned for cost-efficiency to the Co-Programmed and Co-Funded options, a score of 0 to the Article 185 option and a score of (-) for the Article 187 Institutionalised Partnership policy option.

Figure 5 Scoring of costs

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Co- funded	Option 3a: Institutionalised 185	Option 3b: Institutionalised 187
Administrative, operational and coordination costs	0	(0)	(-)	(- -)	(- -)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	(+)	(+)	(0)	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline.

1. Can the Union act? What is the legal basis and competence of the Unions' intended action?
1.1 Which article(s) of the Treaty are used to support the legislative proposal or policy initiative?
<p>This proposal is based on (1) Article 185 TFEU which stipulates that in implementing the multiannual framework programme, the Union may make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; and (2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes (both Articles are under Title XIX of the TFEU - Research and Technological Development and Space).</p> <p>The proposal aims to implement Article 8 of the Commission proposal for Horizon Europe - the future EU research and innovation (R&I) programme for 2021-2027, according to which, “<i>European Partnerships shall be established for addressing European or global challenges only in cases where they will more effectively achieve objectives of Horizon Europe than the Union alone and when compared to other forms of support of the Framework programme</i>”. The Horizon Europe proposal has received the political agreement of the Council and the European Parliament.</p>
1.2 Is the Union competence represented by this Treaty article exclusive, shared or supporting in nature?
<p>Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the European Union can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas.</p> <p><i>Subsidiarity does not apply for policy areas where the Union has exclusive competence as defined in Article 3 TFEU²⁹. It is the specific legal basis which determines whether the proposal falls under the subsidiarity control mechanism. Article 4 TFEU³⁰ sets out the areas where competence is shared between the Union and the Member States. Article 6 TFEU³¹ sets out the areas for which the Unions has competence only to support the actions of the Member States.</i></p>

²⁹ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E003&from=EN>

³⁰ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E004&from=EN>

³¹ <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:12008E006:EN:HTML>

2. Subsidiarity Principle: Why should the EU act?

2.1 Does the proposal fulfil the procedural requirements of Protocol No. 2³²:

- Has there been a wide consultation before proposing the act?
- Is there a detailed statement with qualitative and, where possible, quantitative indicators allowing an appraisal of whether the action can best be achieved at Union level?

This proposal and the accompanying impact assessment were supported by a wide consultation of stakeholders, both during the preparation of the Horizon Europe proposal and - later on, all the candidates for European Partnerships. Member States were consulted via the Shadow Strategic configuration of the Horizon Europe Programme Committee. On candidates for institutionalised Partnerships based on Article 185/187 of the TFEU, an Open Public Consultation (OPC) was held between 11 September and 6 November 2019. Over 1 600 replies were received. In addition, targeted consultation activities were undertaken to prepare the present impact assessment. In particular, for each of the candidate partnerships, an external consultant interviewed a representative sample of stakeholders. The need for EU action as well as its added value were covered in those interviews.

The explanatory memorandum and the impact assessment (horizontal part, Section 3) contain a dedicated section on the principle of subsidiarity, as explained in question 2.2 below.

2.2 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the conformity with the principle of subsidiarity?

The impact assessment accompanying the proposal features a horizontal part on relevant common elements to all the candidate partnerships, including the conformity of the proposed initiative with the principle of subsidiarity (Section 3). Moreover, the individual assessments of each candidate partnership include additional details on subsidiarity, touching in particular on the specificities of a candidate partnership that could not be adequately reflected in the horizontal part of the impact assessment. This will also be reflected in the explanatory memorandum.

2.3 Based on the answers to the questions below, can the objectives of the proposed action be achieved sufficiently by the Member States acting alone (necessity for EU action)?

National action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives, to deliver on the EU's strategic policy priorities (including the climate and energy goals set out in the Paris Agreement, and the European Green Deal), and to contribute to tackling global challenges and meeting the

³² <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12016E/PRO/02&from=EN>

Sustainable Development Goals (SDGs).

(a) Are there significant/appreciable transnational/cross-border aspects to the problems being tackled? Have these been quantified?

The thematic areas covered by the candidate partnerships feature a series of challenges in terms of cross-border/transnational aspects, need to pool resources, need for a critical mass to meet intended policy objectives, need to coordinate different types of actors (e.g. academia, industry, national and regional authorities) across different sectors of the economy and society, which cannot be tackled to the same degree by Member States alone. This is particularly true for the research and innovation (R&I) dimension of the proposed initiative: the importance of a multi-centre and interdisciplinary approach, cross-country data collection and research, and the need to develop and share new knowledge in a timely and coordinated manner to avoid duplication of efforts are key to achieve high quality results and impact. The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide extensive qualitative and quantitative evidence on the above points. In addition, Sections 1 and 2 of the individual impact assessments on the candidate partnerships include more detail on the necessity to act at EU-level in specific thematic areas. Finally, it is worth noting that not all Member States have the same capacity or R&I intensity to act on these challenges. As the desired policy objectives can be fully achieved only if the intended benefits are widespread across the Member States, this requires action at the EU-level.

(b) Would national action or the absence of the EU level action conflict with core objectives of the Treaty³³ or significantly damage the interests of other Member States?

As per Article 4(3) TFEU, national action does not conflict with core objectives of the Treaty in the area of R&I. The absence of EU level action in this area would however prevent the achievement of core objectives of the Treaty. Indeed, national action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives on e.g. competitiveness, to deliver on the EU's strategic policy priorities, and to contribute to tackling global challenges and meet the Sustainable Development Goals (SDGs).

(c) To what extent do Member States have the ability or possibility to enact appropriate measures?

As foreseen by Article 4(3) TFEU, this proposal does not hamper Member States' ability to enact appropriate measures in the field of R&I. However, the scale and complexity of the policy objectives pursued by the present initiative cannot be fully addressed by acting at national level alone.

(d) How does the problem and its causes (e.g. negative externalities, spill-over effects)

³³ https://europa.eu/european-union/about-eu/eu-in-brief_en

<p>vary across the national, regional and local levels of the EU?</p>
<p>As described in the horizontal part of the impact assessment accompanying the present proposal, several problems (e.g. on competitiveness, global challenges, demographic change) and their underlying causes affect the EU as a whole rather than individual Member States. Where important differences between Member States are present, these are described in Sections 1 and 2 of the individual impact assessments.</p>
<p>(e) Is the problem widespread across the EU or limited to a few Member States?</p>
<p>The problem of coordinating R&I efforts in the thematic areas covered by the candidate partnerships affects all Member States, albeit to different degrees. However, from a general EU perspective, available evidence shows that the EU as a whole needs to step up efforts and investments in thematic areas that are crucial to tackle present and future policy challenges on several fronts, e.g. ageing population, global technological trends, and climate change to name a few. The way these problems affect the EU and its Member States is described in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual impact assessments.</p>
<p>(f) Are Member States overstretched in achieving the objectives of the planned measure?</p>
<p>As indicated in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual assessments, the sheer scale, speed and scope of the needed support to R&I would overstretch national resources, without guaranteeing the achievement of the intended objectives. Acting at EU-level would achieve greater impact in a more effective and efficient manner.</p>
<p>(g) How do the views/preferred courses of action of national, regional and local authorities differ across the EU?</p>
<p>No specific differences between the views of national, regional and local authorities emerged from the stakeholder consultation.</p>
<p>2.4 Based on the answer to the questions below, can the objectives of the proposed action be better achieved at Union level by reason of scale or effects of that action (EU added value)?</p>
<p>EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national initiatives in the same area.</p>

(a) Are there clear benefits from EU level action?

Quantitative and qualitative evidence of the benefits of EU level action are available in the interim evaluation of Horizon 2020 and in the impact assessment of Horizon Europe, among others. An analysis of the emerging challenges in each thematic areas, of the EU's competitive positioning, as well as feedback gathered from different types of stakeholders for the present impact assessment indicate that EU level action remains appropriate also for the present proposal. In addition, the benefits of acting at EU-level have been illustrated by the success and the impact achieved by the predecessors to the proposed initiative.

(b) Are there economies of scale? Can the objectives be met more efficiently at EU level (larger benefits per unit cost)? Will the functioning of the internal market be improved?

EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. This is the case both in terms of effectiveness in achieving intended policy objectives, but also in terms of efficiency. Positive impact is also visible in terms of competitiveness: recent data on EU funded R&I activities indicate that EU-funded teams grow 11.8% faster and are around 40% more likely to be granted patents or produce patents applications than non-EU funded teams. Efficiency gains are also visible in terms of dissemination of results to users beyond national borders, including SMEs and citizens. EU funded R&I is more effective in leveraging private investment. Finally, there are clear additionality benefits (i.e. EU R&I funding does not displace or replace national funding), as the EU focuses on projects that are unlikely to be funded at national or regional level. Overall, this is beneficial to the functioning of the internal market in several respects, including human capital reinforcement through mobility and training, the removal of barriers to cross-border activity for economic players including SMEs, easier access to finance and to relevant knowledge and research, and increased competition in the area of R&I.

(c) What are the benefits in replacing different national policies and rules with a more homogenous policy approach?

A homogeneous policy approach in the various thematic areas covered by the present proposal would reduce fragmentation and increase efficiency and effectiveness in meeting the intended policy objectives. Indeed fragmentation, persisting barriers in the internal market and differences in the resources available to Member States are some of the key problems that stand in the way of fully achieving the intended policy objectives and reaching the required critical mass to obtain tangible results. Specific detail on how these issues differ in each thematic area are illustrated in Sections 1 and 2 of the individual impact assessments, so as to reflect the specificities of each case.

(d) Do the benefits of EU-level action outweigh the loss of competence of the Member States and the local and regional authorities (beyond the costs and benefits of acting at

national, regional and local levels)?
The proposed initiative does not lead to a loss of competence of the Member States. In fact, the proposed initiative should be seen as complementary and reinforcing national and sub-national initiatives in the same area. Previous quantitative and qualitative assessments of Horizon Europe and Horizon 2020 have shown that the proposed EU-level action do not displace national ones and tend to concentrate on initiatives that would not have been funded by the Member States themselves, or would not have reached the same scale and ambition without EU-level intervention, due to their complexity and trans-national nature.
(e) Will there be improved legal clarity for those having to implement the legislation?
Yes. The proposed initiatives will be implemented in line with the Horizon Europe single set of rules for participation; this will ensure increased clarity and legal certainty for end beneficiaries, other stakeholders and programme administrators. It will also reduce the administrative burden for beneficiaries, and for the Commission services. In addition, the accessibility and attractiveness of the broader Horizon Europe programme, in particular for applicants with limited resources, would be sustained.
3. Proportionality: How the EU should act
3.1 Does the explanatory memorandum (and any impact assessment) accompanying the Commission’s proposal contain an adequate justification regarding the proportionality of the proposal and a statement allowing appraisal of the compliance of the proposal with the principle of proportionality?
The principle of proportionality underpins the entire analysis of the candidate partnerships. Specifically, the analysis included in the accompanying impact assessment is structured along the following logic: 1. Justification of the use of a partnership approach in a given area (including considerations on additionality, directionality, link with strategic priorities) instead of other forms of intervention available under Horizon Europe; 2. If the partnership approach is deemed appropriate, proportionality considerations guide the assessment of which type of partnership intervention (collaborative calls, co-programmed, co-funded or institutionalised partnership) is most effective in achieving the objectives. This will also be reflected in the explanatory memorandum.
3.2 Based on the answers to the questions below and information available from any impact assessment, the explanatory memorandum or other sources, is the proposed action an appropriate way to achieve the intended objectives?
The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the present proposal leaves full freedom to the Member States to

pursue their own actions in the policy areas concerned. This will also be reflected in the explanatory memorandum.

(a) Is the initiative limited to those aspects that Member States cannot achieve satisfactorily on their own, and where the Union can do better?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments.

(b) Is the form of Union action (choice of instrument) justified, as simple as possible, and coherent with the satisfactory achievement of, and ensuring compliance with the objectives pursued (e.g. choice between regulation, (framework) directive, recommendation, or alternative regulatory methods such as co-legislation, etc.)?

For each of the candidate partnerships, the analysis carried out in the accompanying impact assessment has explored several options for implementation. A comparative assessment of the merits of each option also included an analysis of the simplicity of the intervention, its proportionality and effectiveness in achieving the intended objectives. This is reflected in the fact that a tailored approach has been suggested for each candidate partnership, ranging from looser forms of cooperation to more institutionalised ones, depending on the intended policy objectives, specific challenges, and desired outcome identified in each case.

(c) Does the Union action leave as much scope for national decision as possible while achieving satisfactorily the objectives set? (e.g. is it possible to limit the European action to minimum standards or use a less stringent policy instrument or approach?)

The proposed approach leaves full freedom to the Member States to pursue their own actions in the policy areas covered by the present proposal.

(d) Does the initiative create financial or administrative cost for the Union, national governments, regional or local authorities, economic operators or citizens? Are these costs commensurate with the objective to be achieved?

The proposed initiatives do create financial and administrative costs for the Union, national governments and, depending on the chosen mode of implementation, for regional and local authorities. In addition, economic operators and other stakeholders potentially involved in the candidate partnerships will also incur some costs linked to implementation. The financial cost of the proposed initiative is covered under the Horizon Europe programme. Its exact amount is still subject to political decision. As regards the candidate partnerships and the different modes of implementation (co-programmed, co-funded, institutionalised), the relevant costs and benefits are assessed in the individual impact assessments covering each candidate partnership. The additional administrative costs of implementation via partnerships are

limited, when compared to the administrative costs of implementation through traditional calls. As indicated by comparable experience with previous initiatives and in feedback provided by a variety of stakeholders, these costs are expected to be fully justified by the benefits expected from the proposed initiative. Where available, additional details on costs are provided in Annex 3 of the impact assessment.

(e) While respecting the Union law, have special circumstances applying in individual Member States been taken into account?

Where relevant, differences between Member States in capacity and stage of advancement of R&I in specific thematic areas have been taken into account in the individual impact assessments.

Annex 6 Additional background information

1. BACKGROUND INFORMATION FOR ALL INITIATIVES

1.1. Selection criteria of European Partnerships

Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

The necessity test for a European Partnership (as set out in the Horizon Europe regulation) has two levels:

1. **The justification for implementing a priority with a European Partnership** to address Horizon Europe and EU priorities. This is linked to demonstrating that a European Partnership can produce added value beyond what can be achieved through other Framework Programme modalities, notably traditional calls in the work programmes (Option 0 – Baseline).
2. **The justification for the use of the form of Institutionalised Partnership:** Once it has been demonstrated that a partnerships approach is justified, co-programmed and/or co-funded forms are considered for addressing the priorities as they are administratively lighter, more agile and easier to set-up (Options 1 and/or 2). As Institutionalised Partnerships require setting up a legal framework and the creation of a dedicated implementation structure, they have to justify higher set-up efforts by demonstrating that it will deliver the expected impacts in a more effective and efficient way, and that a long-term perspective and high degree of integration is required (Option 3).

The outcomes of the ‘necessity test’ is presented together with the preferred option.

Figure 6 Horizon Europe selection criteria for the European Partnerships

Common selection criteria & principles	Specifications
1. More effective (Union added value) clear impacts for the EU and its citizens	Delivering on global challenges and research and innovation objectives
	Securing EU competitiveness
	Securing sustainability
	Contributing to the strengthening of the European Research and Innovation Area
	Where relevant, contributing to international commitments

Common selection criteria & principles	Specifications
2. Coherence and synergies	Within the EU research and innovation landscape
	Coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions
3. Transparency and openness	Identification of priorities and objectives in terms of expected results and impacts
	Involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness
	Clear modalities for promoting participation of smes and for disseminating and exploiting results, notably by smes, including through intermediary organisations
4. Additionality and directionality	Common strategic vision of the purpose of the European Partnership
	Approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level
	Demonstration of expected qualitative and significant quantitative leverage effects, including a method for the measurement of key performance indicators
	Exit-strategy and measures for phasing-out from the Programme
5. Long-term commitment of all the involved parties	A minimum share of public and/or private investments
	In the case of institutionalised European Partnerships, established in accordance with article 185 or 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments

1.2. Overview of potential functions for a common back office among Joint Undertakings

Functions	Current situation	Option of joint back-office	Comments
Organising calls for grant and proposal evaluations	Each JU organises this independently.	A central organisation of evaluation, logistics, contracting evaluators, managing the data of the evaluation results Central database of potential evaluators with domain expertise in thematic areas of partnerships	The evaluations would still need to be supervised by the Scientific staff of the individual Joint Undertakings (consensus meetings of expert evaluators etc)
Human Resources related matters	Each JU has own HR policy and resources Quite some resources spent on recruitment in some JUs	More generic resources and expertise for HR matters More consistency in HR	Ensuring consistency with EC HR policies is already in place

	Some HR facilities are procured from external contractors Some JUs have a Service Level Agreement with COM for HR	policy Shared HR investment for specialised expertise (IP and legal)	
Financial management	Each JU conducts own financial contract management; differences between JUs Each JU is audited separately. Auditing at project level more frequent than in other Horizon 2020 parts and outsourced by JUs thus differences ECA: too many audits on JUs	Financial management by one core team of financial staff Would reduce the number of interfaces for audits and simplifies the auditing of the all JUs Harmonisation of project auditing	Simplifies the harmonisation of financial management across JUs in line with Horizon Europe
Communication (internal and external)	Each JU has a separate communication strategies, teams and resources	A common back-office can support activities such as event organisation, dissemination of results, setting up website communication Can help create a more visible Partnership brand	A considerable share of communication activity is partnership specific (addressing particular target groups, synthesising project results) however there are generic communication activities that can be shared Needs to avoid duplication of efforts
Data management on calls, project portfolios, information on project results	Most JUs but not all use e-Corda for project data Overall IT integration of JUs still difficult	Harmonised data management Reduction of IT systems and support that is procured	This will need to happen regardless of the common back office but will likely be more smooth if managed centrally

2. BACKGROUND INFORMATION FOR THIS SPECIFIC INITIATIVE

2.1. Bio-economy and the bio-based industry: definitions and background information

The **bioeconomy** is defined as, “all sectors and systems that rely on biological resources (animals, plants, micro-organisms and derived biomass, including organic waste), their functions and principles. It includes and interlinks: land and marine ecosystems and the services they provide; all primary production sectors that use and produce biological resources (agriculture, forestry, fisheries and aquaculture); and all economic and industrial sectors that use biological resources and processes to produce food, feed, bio-based products, energy and services.. Its sectors and industries³⁴ have strong innovation potential due to their use of a wide range of sciences, enabling and industrial technologies, along with local and tacit knowledge³⁵.” While **biotechnology** is at the heart of **bio-based processes**, health biotechnology and biological medicines are not included in the European Union’s (EU) bioeconomy definition. According to the Joint Research Centre³⁶, in 2015 the bioeconomy in the EU-28 generated ~EUR 2.3 trillion of turnover, which was a 5% increase from 2014. Applying the newest methodology, the JRC estimates³⁷ that in 2015 for the EU-28 the bioeconomy reached €1,460.6 billion value added, which is 11% of the GDP. **Bio-based industries** accounted for over EUR 600 billion of this total. However, it should be noted that in their review of quantitative approaches for measuring the contribution of the bioeconomy to the total economy, authors stress the lack of harmonized approaches for cross-country comparison, with the exception of the European Commission Joint Research Centre (JRC) dashboards for the EU Member States. The quantification reported in these dashboards follows a methodology elaborated by the JRC in collaboration with the nova-Institute. As example of measurements of bioeconomy size, JRC estimates that 20% of the Finnish chemical industry contributed to the bioeconomy in 2015, whereas the bio-based proportion of the same industry was estimated at 36% by the Natural Resources Institute Finland (Luke) for the same year. This implied a variation in the value added of the bio-based chemical industry ranging from €348,000 (JRC) to €734,000 (Luke). Because of methodological heterogeneities, the JRC reports the size of Finland’s bioeconomy to be €13 billion, or 7% of the GDP in 2015, based on the value added approach, whereas the official statistics of Luke indicate considerably higher values of €21.3 billion or 12% of the GDP. Such a large difference highlights the need for a more objective, unified approach to quantify the size of the bioeconomy. The JRC estimate that the bioeconomy added EUR 621 billion of value in the EU, representing 4.2% of the EU’s Gross Domestic Product (GDP) and provided employment to over 18 million persons in the EU, mainly in agriculture and the manufacture of food and beverages. **Bio-based industries** employ ~4 million people in the EU³⁸. In 2015, the highest value-added annual growth occurred in the manufacture of bio-based chemicals (excluding biofuels) (+26%), bio-electricity production (+15%) and rubber and bio-based plastics manufacture (+13%), generating altogether an additional EUR 3.5 billion of value

³⁴ *Bio-based industries include: forest-based industries, bio-based chemicals and plastics, paper & paper products, biofuels & bioenergy, bio-based textile sector and pharma.*

³⁵ European Commission. A sustainable bioeconomy for Europe: strengthening the connection between economy, society and the environment-Updated bioeconomy strategy. European Commission (2018).

³⁶ European Commission. Brief on jobs and growth of the bioeconomy 2009-2015. European Commission’s Knowledge Centre for Bioeconomy, Joint Research Centre.

³⁷ European Commission. How big is the bioeconomy (2020), Joint Research Centre

³⁸ Cefic. Landscape of the European Chemical Industry 2018

added compared to 2014³⁹. Further, it is estimated that one million new jobs could be created in the bio-based industries by 2030. It is anticipated that the biotechnology sector will play a key role in realising this potential⁴⁰.

The transition to a bio-based economy is powered by several drivers. These include⁴¹;

- the need to develop an environmentally, economically and socially sustainable global economy
- an over-dependency of many countries on fossil fuel imports and therefore their need to diversify energy sources
- the anticipation that fossil fuels such as oil, gas and coal will reach peak production soon
- tackling climate change by taking measures to reduce GHG emissions
- and the need to stimulate regional and rural development.

For instance, by replacing fossil-based products with bio-based products (which tend to have a smaller carbon footprint⁴²) the chemical industry can make a critical contribution to the EU's climate goals, whilst simultaneously generating new job opportunities in the regions⁴³. There is potential in major industrial sectors such as chemicals and plastics to replace fossil-based carbon with renewable and recycled carbon as raw materials. Sources of renewable and recycled carbon⁴⁴ are as follows: • renewable carbon gained from all types of biomass • recycled carbon from recycling of already existing plastics and other organic chemistry products (mechanical and chemical recycling) • recycled carbon from direct CO₂ utilisation of fossil point sources (while they still exist) as well as from permanently biogenous point sources and direct air capture.

Globally, governments and private companies are already providing support and investing in the transformation of the chemical industry⁴⁵. Further, most of the large chemical and pharmaceutical producers have sustainability high on their agendas. Many of them are setting targets to improve the sustainability of their products in the mid to long term to 2050⁴⁶. To achieve these targets businesses are improving sustainability in their entire value chains by considering: sustainable feedstock for their products, use of renewable energy in the manufacturing process, and reducing the environmental impact of the product end-of-life and disposal.

In the EU, the European Environmental Agency (EEA) has been advising that bio-based and biodegradable alternatives to fossil equivalents should be used where the risk of dispersion into the ecosystem is high, e.g. lubricants, materials that are subject to wear and tear, and disposable products.

⁴⁵ LBNet. UK Top Bio-based Chemicals Opportunities (2017)

⁴⁶ LBNet. UK Top Bio-based Chemicals Opportunities (2017)

The raw materials used by the chemicals industry are ~50% organic (fossil and bio-based) and ~50% inorganic (minerals, metals)⁴⁷. The chemicals, plastics and pharmaceuticals sectors include several fully bio-based (e.g. natural dyes and pigments, enzymes, fatty acids) and partly bio-based products. Based on Eurostat data, in 2015, out of 534 products in the NACE Division 20 (Manufacture of chemicals and chemical products), 110 products were fully or partly bio-based. Around 40% of these 110 products were 100% bio-based (e.g. tanning extracts of vegetable origin, sorbitol, tall oil), 24% of these products had a bio-based share of at least 10% (e.g. ethylene glycol, carboxylic acid, adipic acid) and the remaining 36% of products had lower bio-based shares (e.g. acetic acid, methanol, epoxy resins). Most of the products (424 in total) in the NACE Division 20 are therefore non bio-based⁴⁸. Hence, there is potential to increase the share of bio-based in partly bio-based products, and to research and develop methods for manufacturing bio-based versions of fossil-based products.

Environmental benefits

Chemicals or materials produced from biomass can help to reduce CO₂ emissions, by replacing fossil-based resources and feedstocks. Any fossil-based ingredient can be replaced by renewable biomass resources or biomass residues. The carbon in fossil resources was captured millions of years ago and is released at the fossil-based products' end of life. This release of carbon dioxide (CO₂) contributes to an increase of greenhouse gas concentration in the atmosphere. Greenhouse gases are one of the major drivers of climate change. To stay below the 1.5-2°C target of global warming, 70% of all coal reserves and at least one third of oil and natural gas reserves need to stay in the ground or their CO₂ emissions have to be kept from entering the atmosphere. In comparison, CO₂ released by renewable resources was recently captured and will be captured again when biomass is regrown to produce new products. This way, the carbon is kept in a shorter cycle (under sustainable cultivation practices). When biomass is used instead of fossil resources, fossil carbon can remain in the ground. This way, renewable biomass resources contribute to limiting climate change and global warming. As bio-based products are produced from plants that have sequestered atmospheric carbon dioxide during their growth, they can help reduce carbon dioxide emissions associated with fossil-based plastic and contribute to climate change mitigation. For example, bio-based polyethylene resin produced by the Brazilian bioplastic company Braskem sequesters 2.15 tonnes of CO₂eq. for every tonne of resin produced i.e. it acts as a carbon sink. In comparison, the production of traditional oil-based polyethylene emits 1.83 tonnes of CO₂eq⁴⁹. However, it should be noted that most bio-based plastics have the same product characteristics as their traditional oil-based equivalent. For example, bio-based PET is identical to fossil-based PET. Simply because a bio-based plastic is made from natural resources doesn't mean it is biodegradable. Bio-based plastics can be just as durable as oil-based plastic. Bio-based plastic with improved barrier properties for gases (e.g. carbon dioxide and oxygen) can lead to a longer shelf-life of packaged products. Synvina's recyclable PEF⁵⁰ offers a significant advantage to the packaging industry in comparison to alternative

⁴⁸ Piotrowski S, Carus M, Carres D. European Bioeconomy in Figures 2008-2015: Update, April 2018

⁴⁹ NNFCC, 2018. Market Perspective: Bio-based & Biodegradable Plastic in the UK (2019)

⁵⁰ Synvina, n.d. PEF – Game-changing plastic. Available at: <https://www.synvina.com/products/pef/> Date last accessed: 29/03/2019. PEF is referred as the next generation polyester with high potential to replace polyethylene terephthalate (PET), a durable fossil-based polymer. PEF offers numerous benefits compared to PET, such as, superior barrier performance as well as mechanical and thermal properties; high glass transition temperature and lower melting point; recyclable and hence reduced carbon footprint. It cost competitive at industrial scale.

bio-based plastics or barrier materials. Moreover, it also offers a higher mechanical strength, thus thinner PEF packaging can be produced and fewer resources are required. PEF is suitable as the main component or as a barrier layer in cups and trays, flexible packaging as well as bottles for carbonated and non-carbonated soft drinks, water, dairy products, still and sports drinks, alcoholic beverages as well as personal and home care products. An important challenge for the growth of bio-based plastics is the communication of sustainability drivers and credentials to raise awareness, social acceptance and uptake of bio-based plastic products. Therefore, the entire value chain must ensure accurate knowledge transfer to the brand-owners to make correct and poignant labelling for the end-consumer to understand any positive environmental impact of their choice to purchase a bio-based plastic product.

Low toxicity of bio-based products is an important benefit for both environment and consumer use, e.g. in specific sectors of bio-based industry such as packaging for food contact, or cosmetics. Petro-chemical alternatives never satisfy the natural-based attribute and could potentially be more toxic in comparison. Manufacturers also use popular ingredients from the health and food sectors in cosmetic products. Different biobased materials (strictly from biomass and not inorganic materials) have different functionalities. For example, substances extracted from plants and other types of biomass can be used to increase shelf life and protect against UV degradation. Many natural substances have bioactive effects such as preserving, healing, anti-inflammatory or emollient effects. Low toxicity is an important environmental benefit of bio-based agrochemicals, which can contribute to biodiversity preservation, especially if combined with sustainable management of biomass cultivation (e.g. mixed rotation systems, agro-forestry, use of perennial crops, use of certification schemes etc). Bio-based crop protection products start degrading soon after application resulting in little or no toxic residue^{51,52}. However, the drawback is that they need to be applied more frequently in order to be effective. Examples of crop protection products include vegetable or fish oils as well as plant essential oils.

As a result of the potential toxicity, often even at very low levels, the application of crop protection products is strictly regulated in Europe⁵³. Policy control measures in the EU are driven by the objectives of protecting human health and the environment (consumers, operator safety, protection of water quality and biodiversity).

European resource independence

A strong European bioeconomy would replace fossil-based products with renewable alternatives, and reduce the EU's dependency on fossil resources like oil, coal and natural gas. Biomass resources can be grown locally in the EU, in contrast to fossil resources, of which the majority is imported. In the long run, the organic chemistry will strive to become circular and apply reusable raw materials to become largely independent from limited fossil resources.

⁵³ Eurostat, 2018. Agri-environmental indicator - consumption of pesticides

This could in the future also be achieved with recycling and CO₂ utilisation, but currently biomass is the most readily available option.

The sustainability challenge

Studies have shown considerable potential for the cultivation of biomass for energy and material use on a global level, even under consideration of sustainability criteria such as biodiversity preservation, climate protection or food security. In a sustainable bioeconomy, cultivation and processing of biomass has to be based on sustainable agriculture and forestry, where environmental aspects as well as social and labour standards are given serious consideration. Besides agriculture and forestry, residual biomass can be an important resource for a sustainable bioeconomy. Strong instruments to support the development of a sustainable bioeconomy are certification schemes and labels for renewable raw materials and bio-based products.

The European chemical industry needs to step up the efforts on the path to actively increase its sustainability. One of the goals is to make products that are less harmful to the environment and less toxic to the consumers, and environment, but perform just as well as conventional products or even better. Sourcing an increasing part of its feedstock from biomass is an important way for the chemical industry to become more sustainable. Substituting fossil resources with biomass generally leads to reduced GHG emissions and is an important tool to reach our climate targets. The current share of renewable raw material use in the EU organic chemical industry was estimated by Cefic at around 10% in 2015, but the Bio-based Industries Consortium (BBI JU SIRA2017) set the ambition to reach a bio-based feedstock share of 25% by the year 2030. Many technical solutions to replace fossil resources by biomass have already been developed and currently efforts are undertaken to scale up the production of new, more sustainable products made from biomass.

The contribution to UN Sustainable Development Goals

The bioeconomy is at the centre of sustainable development and products made from renewable biomass resources can contribute to achieving the UN Sustainable Development Goals. The production of bio-based chemical products supports in particular the achievement of the following SDGs: SDG 8 - Decent work and economic growth: The bio-based chemical industry can provide new jobs and additional income, in particular in rural communities, and create opportunities to export value-added bio-based products. SDG 9 - Industry, innovation and infrastructure: The bio-based chemical industry is evolving quickly. Many bio-based technologies are entirely new ideas, which require and support innovation and infrastructure development. SDG 11 - Sustainable cities and communities: Bio-based chemistry links surrounding rural areas to urban centres, e.g. by setting up innovative processing plants (“biorefineries”) that transform agricultural residues and parts of municipal solid waste into chemical building blocks. SDG 12 - Responsible consumption and production: The bio-based chemical industry contributes to optimised use of biomass and wastes, decouples production and consumption from fossil energy sources and raises consumer awareness. SDG 13 - Climate action: The use of renewable biomass resources in the chemical industry reduces the use of fossil-based resources and their related greenhouse gas emissions. SDG 15 - Life on land: Through promoting sustainable management of forests and natural resources, bio-based chemistry can support the combat against desertifi

Circularity issues

The bioeconomy can contribute to a circular economy, which helps us to move away from a linear economy of “take, make and dispose”. The bioeconomy and circular economy go hand in hand. Reducing waste and making optimal use of natural resources are important goals of both the circular economy and the bioeconomy. The circular economy strives to reduce resource consumption. Roughly 90% of the raw materials used in manufacturing become waste before the product leaves the factory. And most products get thrown away within the first six months of their life. But even in a fully circular economy, some input of new raw materials remains necessary. Biomass can provide a sustainable input, because it is renewable and regrows naturally. Chemicals and materials from biomass are part of the natural cycle. They can provide a sustainable input of new materials for a circular economy. The bioeconomy can furthermore make use of many (organic) waste streams and hereby support the circular economy.

Within agriculture, more than half the globally harvested dry mass consists of agricultural residues and inedible biomass, such as cereal and legume straw; shoots of tuber, oil and sugar; vegetable crop stalks, leaves and shoots; and fruit and nut tree prunings. A major barrier to increasing the use of agricultural and forestry residues are the costs associated with adapting harvest logistics, which are often higher than costs of primary fossil materials. Also, residues are an important factor for soil quality and need to remain on the field to a certain extent in order to avoid the depletion of nutrients. Local biorefining systems that smartly match residue supply and material demand need to be developed, as the wide dispersal of residues does not fit the economies of scale of the existing industrial oilbased production system.

– Municipal solid waste contains food waste, which is a potential feedstock for the bio-based chemistry – signifying a high amount of fermentable materials which are mixed up with non-fermentable materials, which are thus difficult to access.

According to recent insights from the S2Biome project, the amount of available lignocellulosic biomass in the EU by 2030 is estimated to be at least around one billion tonnes. However, the biomass types that are currently used by the chemical industry are mainly sugar (from sugar beets and starchcrops) and vegetable oils such as rapeseed, soya and palm oil. Switching to other types of feedstock proves difficult both from a technical and an economic perspective.

– Marine streams: The oceans offer large opportunities for the cascading use in the bioeconomy. These include for example the use of fisheries discards (~40% of caught fish), algal biorefineries, seaweed farming, multi-use of marine space in off-shore platforms, zero-waste and circular aquaculture, new products from jellyfish, new pharmaceuticals from marine ecosystems. Stakeholders mentioned algae in particular as a promising feedstock choice for the future. The BBI-JU also supports a number of algae-based projects for the bioeconomy, e.g. the ABACUS project, the VALUEMAG project or the MAGNIFICENT project. The results of several previous projects, however, also give reason for some caution of expectations. The utilisation of algae is not easy and so far quite costly.

Focused research and development could be directed towards cascading use and utilizing of currently unused waste streams. There are several EU projects ongoing that focus on the

utilization of such waste streams: Some examples are the Lifecab project⁵⁴, the Embraced project⁵⁵ and the Agrimax project⁵⁶

Empowering primary producers and global best practice

- Enable producers to make informed decisions on the use of their residues
- Ensure that producers are receiving a fair price for collecting waste that can be used as a 3rd generation feedstock.
- Actively involve producers as stakeholders
- Relevant international example: US Biomass Crop Assistance Program, which provides funds to farmers and forester landowners that grow and harvest “non-conventional” biomass. Examples are perennial crops or agricultural and forestry residues, which are intended to be used for energy and bio-based products in biomass conversion facilities. A similar system could be established in the EU, e.g. via the Common Agricultural Policy.

Bringing solutions to the market

Many products on the market are already made from chemicals or materials based on renewable biomass resources, beyond traditional bio-based resources, such as wood or paper. The chemical industry already offers a broad variety of products made from renewable resources. Some examples include: compostable plastic bags, personal care products, natural detergents, plant-based drinking bottles, planting pots for garden use or automotive parts, e.g. insulation materials, or composites with natural fibres used in dashboards. Even though these products are made from biomass, they can look, feel and perform as conventional, fossil-based products or even better. For example, in the building sector, an increasing number of architects and construction companies return to applying construction materials produced from renewable resources, and it is more than just wood for the walls. Insulation, flooring and paints can be made from bio-based materials as well, where they provide a healthier and more comfortable indoor climate. Renewable raw materials are also widely used in cleaning products or packaging sectors. Biotechnology provides bio-based ingredients such as enzymes for detergents. Enzymes can help in reducing the environmental impact of washing and cleaning products by using less energy and water, while providing the same or better cleaning results under milder conditions.

Competitiveness of the EU bio-based industry

In 2015, 10% of the total volume of organic chemicals raw materials/feedstock used for EU chemicals production was bio-based. 2030 aspirational target is to increase bio-based

feedstock use to 25%. Besides the product group specific analysis of barriers (see market segment analysis below), some wider issues exist that concern the chemical industry in the bioeconomy. These are referred to as general barriers, and can be classified according to increasing the bio-based share in the chemical industry into six main categories. For each of these categories, several actions can be attributed.

Barriers 1, 4, 5 and 6 are in direct scope of the present Impact Assessment. The barriers 2 and 3 remain of importance, however can be considered beyond the scope.

Barrier 1. Access to feedstock (including low availability of sustainable biomass, and non-level playing field with competing uses of biomass such as for bioenergy). Actions attributed: Increasing yields of production of biomass, establishing and identifying new sources of feedstock, increasing efficiency of biomass supply chains, developing sustainable biorefineries, and establishing a balance between various types of uses of sustainable biomass.

Barrier 2. Competition with established fossil industry (including bio-based alternatives not cost-competitive, and lower performance of bio-based alternatives). Actions attributed: Implementing market pull instruments (e.g. labelling, procurement, certification), reducing fossil feedstock support, increasing performance characteristics of bio-based products by R&D investments, promoting industry- or voluntary incentives.

Barrier 3. Regulatory barriers (including lack of policy harmonization, limited long-term reliability). Actions attributed: Harmonisation of standards, policies and regulations, providing stability and reducing risk by long-term regulatory policy, guidance, support and clarification for policy for bio-based products.

Barrier 4. Societal barriers (including lack of information, awareness and expertise, or unrealistically high expectations). Actions attributed: promoting labels, standards, improving education and training, design and implement visible, inclusive, transparent and coherent communication effort for the bioeconomy and bio-based sectors, improve participatory approaches and network building, improve social acceptance and promote trust to manage unrealistically high expectations.

Barrier 5. Markets, Finance & Investment (including low availability of funding for early stage and scale-up, low funding for start-ups and SMEs). Actions attributed: developing green investment funding schemes and programmes, reduce high transaction costs for start-ups and scale-up operations, support easier market entry of SMEs e.g. via innovative tax schemes and support measures, strengthen communication channels for financing opportunities.

Barrier 6. Research & Development (including ongoing need for funding, limited guidance and direction of R&D, and limited understand of ecological boundaries and innovation adoption and diffusion). Actions attributed: deploying additional, targeted financial instruments, improving access to finance for R&D opportunities, maximising impact of EU R&D programmes, enhancing knowledge on biodiversity, ecosystems and bioeconomy.

Key market segment study analysis (plastics/polymers, agrochemicals, surfactants, bio-based fibres, solvents, adhesives, cosmetics)

Plastics/polymers

The trend towards bio-based plastics is driven by changing consumer demands with increased awareness of environmental impacts of the plastics industry.

- To make plastic products more resource efficient and to reduce GHG emissions, the emphasis is on increasing the use of renewable feedstock using lower energy processing, while reducing the dependency on fossil resources.
- Several innovative small and large companies are responding to consumer demands towards a more sustainable plastics economy. These companies have made substantial investments in R&D for bio-based plastics designed with the circular economy in mind, e.g. PLA, PEF and bio-PTT.
- Bio-based production of plastics/polymers in Europe is >1,200 kt/yr, while fossil-based production is ~70,000 kt/yr.
- Therefore, out of the analysed product groups, the addressable market of fossil-based plastics/polymers production in Europe is the largest (large addressable market is considered as >10,000 kt).
- Diverse bioplastics are being developed that can be drop-ins, compostable and non-biodegradable, but few are truly biodegradable.
- Some bio-based plastics listed meet the desired sustainability characteristic for low GHG emissions, which is a key driver for thermoplastics. Low human toxicity is an important driver for some thermoplastics used in healthcare and food packaging, e.g. bio-PVC.
- Recyclability is the sustainability characteristic that most conventional plastics and their bio-based alternative plastics already possess. However, some bio-based plastics, such as PLA and PHAs cannot be recycled with current well-established recycling infrastructure and there is evidence that recyclability is a desired sustainability characteristic of these bio-based plastics. Therefore, further R&D in product development and recycling techniques is required to ensure that recyclability does not compromise performance.
- Bio-based drop-ins may not be compostable/biodegradable but would be recyclable – otherwise, biopolymers might conflict with recycling goals. Non-biodegradable biopolymers could also contribute to carbon sequestration.
- Biodegradability is considered an important end-of-life pathway, especially when recycling is no longer technically possible. Additives are available that could increase the rate of biodegradation in treated plastic products, though claims need to be appropriately verified.
- Producers of bio-based plastic should provide adequate labelling to inform customers of types of biobased plastics to raise awareness about bio-based plastic alternatives and end-of-life processing.
- Although TRLs for some the bio-based plastics listed are already at 9, there are some that require further R&D (including investment) and industrial trials to improve technical properties and reduce production costs to successfully grow at commercial scale.

- Some of the leading manufacturers are Genomatica, Versalis, Cargill, Synbra Technology, Novamont, BASF SE, Natureworks, Corbion, Braskem, Secos Group, Biome Technologies, FKUR Kunststoff, Innovia Films, and Toray Industries.

Agrochemicals

There is a growing market for fertiliser coatings that are bio-based and biodegradable, as well as for biostimulants (including chitosan, seaweed extracts) and biological seed treatment (including botanicals).

- Biodegradability, low human toxicity and low ecotoxicity are the desired sustainability characteristics in agrochemicals. However, the bio-based chemical has to at least have the same level of performance as the fossil-based agrochemical.
- Bio-based chemical building blocks such as bio-based lactic acid, methanol and fatty alcohols present an opportunity for converting conventional fossil-based agrochemicals into partly bio-based equivalents. The performance of the latter should be, at least, at par with the fossil-based agrochemicals.
- Bio-based crop protection products start degrading soon after application resulting in little or no toxic residue. However, the drawback is that they need to be applied more frequently in order to be effective. Formulation of bio-based crop protection products can be improved to address this issue.
- New bio-based crop protection products can help address the issue of pesticide resistance in pest populations.
- European agrochemical industry is strictly regulated. Use of new ingredients in products is subject to long and often expensive approval procedures. There is a low risk category within the legislation 1107/2009 that places plant protection products on the market. This could be readily adapted for speedier approval of biobased pesticides and is already ratified by the European Parliament. However, it is yet to be actioned by the European Commission.
- Key actors of European agrochemical industry include: Syngenta, Bayer Crop Science, Corteva (Dow Agrisciences, DuPont and Pioneer merger), BASF, Sipcam- Oxon

Surfactants

Bio-based surfactants are produced as high value products, typically for high-end customer products, such as personal care and home care products.

- Methyl ester sulfonate (MES) offers the biggest opportunity to shift from fossil to bio-based surfactants. It could be a bio-based alternative for linear alkyl benzene sulfonate (LAS) and has high potential to be used in cosmetic products.
- The demand for bio-based surfactants strongly depends on household spending.
- There is drive/requirement for clear labelling, so consumers can increasingly opt to buy product using biobased alternatives.

- The key drivers for bio-based surfactants are their biodegradability, lower human toxicity and lower ecotoxicity, especially in environments where these sustainability characteristics are required.

- Production of bio-based surfactants in Europe is

~1,100 kt/yr, while fossil-based production is ~2,400 kt/yr.

- The addressable market of fossil-based surfactants production in Europe is medium-sized (1,000-10,000 kt/yr) in comparison to the other eight product groups.

- Besides being made from renewable feedstock, the main advantages of bio-based surfactant are possible antimicrobial properties; better performance compared

to fossil equivalents which allows to use smaller quantities of surfactants; better foaming properties; higher selectivity for application at lower temperatures, higher pH and salinity; ability to achieve regulatory compliances with regard to (environmental) safety and use of lowcost feedstocks (i.e. fats and oils, sugars).

- Due to the advanced product properties the use of biobased surfactants is possible in a wide range of product applications (cleaning, personal care, food processing, agrochemicals and textiles). However, these products remain niche due to their limited cost competitiveness compared to conventional products.

- Bio-based surfactants are usually used in end product formulations where the modification of one component has an impact on the overall composition and performance, which causes additional development costs. This cost barrier could be overcome by targeted support and funded research towards new product formulations. The clear advantage for companies is flexibility in composition, as long as a certain performance can be ensured.

- Due to the limited number of large-scale producers a secured steady supply of bio-based surfactants is uncertain which creates risk for suppliers like personal and home care producers.

- Key companies producing bio-based surfactants include Evonik, Ecover, Henkel, Saraya, Soliance, Wheatoleo and Nouryon.

Bio-based fibres

Bio-based man-made fibres production in Europe is >600 kt/yr, while fossil-based production is ~4,800 kt/yr.

- The addressable market of fossil-based man-made fibre production in Europe is medium-sized (1,000-10,000kt) in comparison to the other analysed product groups.

- Consumer demand and initiatives by producers have driven the increase in the use of bio-based and recycled feedstock, as well as sustainability across the man-made fibres supply chain.

- Recyclability is the sustainability characteristic that all conventional and several bio-based alternatives have. However, recycling is not easy in case of blends such as fabric made of polyester and cotton with a small percentage of elastane. Another example is PLA which

cannot be recycled with PET in established recycling infrastructure. Therefore, there is scope for further R&D in recycling techniques for different fibres.

- There is a drive to make conventional plastics such as PET and nylon biodegradable by adding ‘additives’. While these additives are available on the market, the claims of biodegradation rarely pass rigorous testing and review. However, it does show that biodegradability is considered important for synthetic polymers when they approach end-of-life and cannot be recycled anymore.
- The production of some biosynthetic fibres could potentially result in low GHG emissions and some have low toxicity effect.
- Some bio-based fibres, such as bio-PTT, can be produced at lower cost compared to their fossil-based equivalents, and have properties that surpass fossil-based equivalents in fibre applications.
- There are several bio-based man-made fibres that are still at research and demonstration scale. Further R&D and industrial trials are needed to bring these fibres to commercial scale. Example of an ongoing projects in Europe is FIBFAB (H2020 project) on PLA fibre.
- Some of the companies that are actively involved in

bio-based man-made fibres market include: DuPont (Sorona®), Sofila (use Arkema’s Rilsan®), Aquafil, RadiciGroup (Radilon® DT 40EP25W), BASF, Solvay, Distrupol, Sateri (viscose), Lenzing (TENCEL™), AlgiKnit.

Solvents

Bio-based solvents production in Europe is <0.5 kt/yr, while fossil-based production is ~5,000 kt/yr. The addressable market of fossil-based solvents production in Europe is medium-sized (1,000-10,000kt) in comparison to the other eight product groups.

- The uptake of bio-based solvents is driven by the EU policy on VOC emissions and by REACH. Those biobased alternatives which meet the criteria of low toxicity and low VOC, compared to the fossil-based counterpart, are likely to be considered as valid alternative provided that they meet the functionally requirements of the solvent in specific applications.
- Conventional and bio-based solvents identified are biodegradable (some more than others), and there is concerted effort from the industry to recover and recycle solvents where possible. This is driven by legislation that aims to reduce the adverse impact of solvents (VOCs) on human beings and the environment. It should be noted that solvents can be recovered and recycled in some sectors and applications but not in others.
- Industries are taking as many steps as possible to remain competitive, by reducing waste and recycling spent solvents. It is very important for producers, especially the ones who are using solvents for extraction, to be able to recycle and reuse the solvent. Extraction is a common processing step in chemical, food, pharmaceutical and mining industry.
- For products that are likely to end up in the environment, complete biodegradability is a relevant sustainability driver. This is the case of solvents that are typically used in formulation of cleaning products (household cleaners, personal care) or agrochemicals. However, the

biggest industrial end-group in which solvents are used are paints and coatings, in which solvents evaporate after the paint has been applied, thus dissipating into the air. In such cases, biodegradability is not a relevant sustainability driver.

- Many ‘dedicated’ bio-based solvents included in this analysis claim to have low toxicity effects compared to fossil equivalents.
- The production of some identified bio-based solvents has been reported to release less GHG emissions compared to fossil equivalents.
- Bio-based solvents need to meet the functional requirement of the fossil equivalents that they intend to replace in different applications. There is significant scope for R&D and demonstration scale projects to develop a wide range of bio-based solvents and formulations that can be used in different applications.
- Some of the companies actively involved in the biobased solvents market include: Cellulac, BioAmber, Green Biologics, DuPont-Tate & Lyle, Pennakem Europa SAS, Circa, Roquette, Cargill, Solvay-Rhodia

Adhesives

Production cost is an important driver in the adhesives segment.

- The key sustainability driver is to reduce human toxicity by lowering Volatile Organic Compounds (especially for the wood building industry which is one of the most significant markets for adhesives).
- Environmental and health concerns related to formaldehyde create a major opportunity for the development and growth of bio-based chemicals which could replace formaldehyde. Bio-based 5-HMF and lignin derivatives are among the most promising candidates.
- A range of bio-based raw materials such as diacids, diols and natural polyols building blocks are available as a drop-in or dedicated replacement of fossil-based building blocks for adhesives and sealants.
- Keeping suitable mechanical properties while reducing the emission of VOCs is the key development and innovation trend in the adhesives segment.
- Bio-based alternatives must deliver the desired mechanical performance characteristics and water resistance requirements in adhesives. Meeting these requirements may initially rely on the development of mixed bio and fossil-based adhesives.
- Legislation may lead to accelerating the transition from synthetic adhesive to bio-based adhesives by regulating the presence of VOCs and the presence of recyclable materials, especially in the building industries.
- Some companies active in the development of new biobased adhesives are: VTT (Finland), Arkema (France), Weiss Chemie + Technik (Germany) and Covestro (Germany)

Cosmetics

The share of bio-based chemicals in cosmetics produced in the EU is about 40%, which is the highest among all product groups that are considered in RoadToBio.

- European consumers' emerging environmental awareness and a growing trend for natural products is driving the uptake of bio-based chemicals in cosmetics. Costs are less important constraints in the cosmetics segment.
- Biodegradability and low human toxicity are the main desired sustainability characteristics in the cosmetics product group. Bio-based products such as botanical extracts and vegetable oils have these key characteristics. However, bio-based solvents such as acetone are toxic and non-biodegradable, thereby presenting an opportunity for development and commercialisation of novel bio-based solvents that are safe to use and dispose.
- Functional ingredients and chemical building blocks used in cosmetics such as preservatives, solvents and surfactants are still mainly derived from fossil feedstock and therefore not sustainable. • Low GHG emissions is a desired sustainability characteristic for building blocks such as solvents and surfactants that are used in cosmetics. The bio-based chemicals identified in the sample could lead to low GHG emissions compared to the fossil equivalents.
- By volume of use, botanical extracts and vegetable oils outweigh building blocks like lactic acid and succinic acid. In order to attain higher bio-based share in the cosmetics product group, these two subgroups will play a vital role and therefore should be the subject of further research and product development.
- Bio-based preservatives underperform in comparison to the fossil derived ones. This area of cosmetics presents an opportunity for the development and further growth of bio-based chemicals. • European cosmetics industry is strictly regulated. Ingredients such as preservatives, UV-filters, nanomaterials or colorants are subject to long and often expensive approval procedures. Other ingredients must be safe for cosmetic use by meeting the requirements of EU legislations (cf. REACH and Cosmetic Regulation)
- Opportunities also exist in using alternate feedstocks like algae, and technology for the extraction and preservation of bioactive ingredients.

2.2. Glossary

1G feedstock First generation feedstock: the source of carbon is sugar, lipid or starch directly extracted from a plant. The crop is actually or potentially considered to be in competition with food.

2G feedstock Second generation feedstock: the carbon is derived from cellulose, hemicellulose, lignin or pectin. For example this may include agricultural, forestry wastes or residues, or purpose-grown non-food feedstocks (e.g. Short Rotation Coppice, Energy Grasses).

3G feedstock Third generation feedstock: the carbon is derived from aquatic autotrophic organism (e.g. algae). Light, carbon dioxide and nutrients are used to produce the feedstock "extending" the carbon resource available for biochemicals production. This means, however, that a heterotrophic organism (using sugar or cellulose to produce biochemicals) would not be considered as 3G.

Bio-based drop-in chemicals: bio-based versions of existing petrochemicals which have established markets. They are chemically identical to existing fossil-based chemicals.

Bio-based smart drop-in chemicals: a special sub-group of drop-in chemicals. They are also chemically identical to existing chemicals based on fossil hydrocarbons, but their bio-based pathways provide advantages compared to the conventional pathways.

Drop-in chemicals are considered to be ‘smart drop-ins’ if at least two of the following criteria apply:

- The Biomass Utilization Efficiency from feedstock to product is significantly higher compared to other drop-ins.
- Their production requires significantly less energy compared to other production alternatives.
- Time-to-product is shorter due to shorter and less complex production pathways compared to the fossil-based counterpart or other drop-ins.
- Less toxic or harsh chemicals are used or occur as by-products during their production process compared to the fossil-based counterpart or other drop-ins.

Dedicated bio-based chemicals: chemicals which are produced via a dedicated pathway and do not have an identical fossil-based counterpart. As such, they can be used to produce products that cannot be obtained through traditional chemical reactions and products that may offer unique and superior properties that are unattainable with fossil-based.

PART 1 - COMMON FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1. BACKGROUND AND CONTEXT TO EUROPEAN PARTNERSHIPS IN HORIZON EUROPE AND FOCUS OF THE IMPACT ASSESSMENT– WHAT IS DECIDED

1.1. Focus and objectives of the impact assessment

This impact assessment accompanies the Commission proposal for Institutionalised European Partnerships to be funded under Horizon Europe, the 2021-2027 Framework Programme for EU Research and Innovation (R&I).¹ It sets out to **help decide in a coordinated manner the right form of implementation for specific candidate initiatives** based on a common approach and methodology to individual assessments². It also provides an **horizontal perspective on the portfolio of candidate European Partnerships** to identify further efficiency and coherence gains for more impact.

European Partnerships are initiatives where the Union, together with private and/or public partners (such as industry, public bodies or foundations) commit to support jointly the development and implementation of an integrated programme of R&I activities. The rationale for establishing such initiatives is to achieve the objectives of Horizon Europe more effectively than what can be attained by other activities of the programme.³

Based on the Horizon Europe Regulation, European Partnerships may be set up using **three different forms**: “Co-funded”, “Co-programmed” and “Institutionalised”. The setting-up of **Institutionalised Partnerships** involves new EU legislation and the establishment of dedicated implementing structures based on Article 185 or 187 of the Treaty on the Functioning of the EU (TFEU). This requires an impact assessment to be performed.

The Horizon Europe Regulation defines **eight priority areas**, scoping the domains in which Institutionalised Partnerships could be proposed⁴. Across these priority areas, **13 initiatives** have been identified as **suitable candidate initiatives** for Institutionalised Partnerships because of their objectives and scope. This impact assessment aims to identify whether 12 of these initiatives⁵ need to be implemented through this form of implementation and would not deliver equally well with traditional calls of Horizon Europe or other lighter forms of European Partnerships under Horizon Europe. This means assessing whether each of these initiatives meets the necessity test set in the **selection criteria** for European Partnerships in the Horizon Europe Regulation, Annex III.

This assessment is done **without any budgetary consideration**, as the overall budget of the Multiannual Financial Framework of the EU – and hence of Horizon Europe – for the next financing period is not known at this stage.⁶

¹ Horizon Europe Regulation (common understanding), <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

² Based on the European Commission Better Regulation framework (SWD (2017) 350) and supported by an external study coordinated by Technopolis Group (to be published in 2020).

³ For further details on these points, see below Section 1.2.2.

⁴ Set out in the Annex Va of the Horizon Europe Regulation (common understanding). <https://data.consilium.europa.eu/doc/document/ST-7942-2019-INIT/en/pdf>

⁵ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47).

⁶ EU budget commitments to the European Partnership candidates can only be discussed and decided following the political agreement on the overall Multiannual Financial Framework and Horizon Europe budgetary

1.2. The political and legal context

1.2.1. Shift in EU priorities and Horizon Europe framework

European priorities have evolved in the last decades, and reflect the social, economic, and environmental challenges for the EU in the face of global developments. In her Political Guidelines for the new European Commission 2019 – 2024⁷, the new Commission President put forward six overarching priorities, which reach well beyond 2024 in scope⁸. Together with the Sustainable Development Goals (SDGs), these priorities will shape future EU policy responses to the challenges Europe faces, and thus also give direction to EU research and innovation.

As part of the Multi-annual Financial Framework (MFF) 2021-27 the new EU Framework Programme for Research and Innovation **Horizon Europe will play a pivotal role for Europe to lead the social, economic, and environmental transitions needed to achieve these European policy priorities**. It will be more impact driven with a strong focus on delivering European added value, but also be more effective and efficient in its implementation.⁹ Horizon Europe finds its rationale in the daunting challenges that the EU is facing, which call for *“a radical new approach to developing and deploying new technologies and innovative solutions for citizens and the planet on a scale and at a speed never achieved before, and to adapting our policy and economic framework to turn global threats into new opportunities for our society and economy, citizens and businesses.”* While Horizon Europe continues the efforts of strengthening the scientific and technological bases of the Union and foster competitiveness, a more strategic and impact-based approach to EU R&I investment is taken. Consequently, the **objectives of Horizon Europe** highlight the need *to deliver on the Union strategic priorities and contribute to the realisation of EU objectives and policies, contribute to tackling global challenges, including the Sustainable Development Goals by following the principles of the Agenda 2030 and the Paris Agreement.*¹⁰

In this context, **at least 35 % of the expenditure from actions under the Horizon Europe Programme will have to contribute to climate action**. Furthermore, a **Strategic Plan** is co-designed with stakeholders to identify **key strategic orientations for R&I support** for 2021-2024 in line with the EU priorities. In the Orientations towards the first Strategic Plan for Horizon Europe, the need to strategically prioritise and *“direct a substantial part of the funds towards the areas where we believe they will matter the most”* is emphasised. The Orientations specify, that actions under Pillar II of Horizon Europe “Global Challenges and European Industrial Competitiveness” will target only selected themes of especially high impact that significantly contribute to delivering on the political priorities of the Union. Most of the candidate European Partnerships fall under this Pillar.

envelopes. The level of EU contribution for individual partnerships should be determined once there are agreed objectives, and clear commitments from partners. Importantly, there is a ceiling to the partnership budgets in Pillar II of Horizon Europe (the legal proposal specifies that *the majority of the budget in pillar II shall be allocated to actions outside of European Partnerships*).

¹⁰ Article 3, Common understanding regarding the proposal for Horizon Europe Framework Programme.

1.2.2. Key evolutions in the approach to partnerships in Horizon Europe

Since their start in 1984 the successive set of Framework Programmes uses a variety of instruments and approaches to support R&I activities, address global challenges and industrial competitiveness. Collaborative, competition-based and excellence-driven R&I projects funded through Work Programmes are the most traditional and long-standing approach for implementation. Since 2002, available tools also include **partnerships**, whereby the Union together with private and/or public partners commit to jointly support the development and implementation of a R&I programme. These were introduced as part of creating the European Research Area (ERA) to align national strategies and overcome fragmentation of research effort towards an increased scientific, managerial and financial integration of European research and innovation. Interoperable and integrated national research systems would allow for better flows of knowledge, technology and people. Since then, the core activities of the partnerships consist of building critical mass mainly through collaborative projects, jointly developing visions, and setting strategic agendas.

As analysed in the **interim evaluation of Horizon 2020**¹¹, a considerable repertoire of partnership initiatives have been introduced over time, with 8 forms of implementation¹² and close to 120 partnership initiatives running under Horizon 2020 - without clear exit strategies and concerns about their degree of coherence, openness and transparency. Even if it is recognised that these initiatives allow setting long-term agendas, structuring R&I cooperation between otherwise dispersed actors, and leveraging additional investments, the evaluation points to the complexity generated by the proliferation of instruments and initiatives, and their insufficient contribution to policies at EU and national level.

Box 1 Key lessons from the interim evaluation of Horizon 2020 and R&I partnerships

- The **Horizon 2020 Interim Evaluation** concludes that the overall partnership landscape has become overly complex and fragmented. It identifies the need for rationalisation, improve their openness and transparency, and link them with future EU R&I missions and strategic priorities.
- The **Article 185 evaluation** finds that these public-public partnerships have scientific quality, global visibility and networking/structuring effects, but should in the future focus more on the achievement of policy impacts. From a systemic point of view, it found that the EU public-to-public cooperation (P2P) landscape has become crowded, with insufficient coherence.
- The **Article 187 evaluation** points out that Public-Private Partnership (PPP) activities need to be brought more in line with EU, national and regional policies, and calls for a revision of the Key Performance Indicators. As regards the **contractual PPPs (cPPPs)** their reviews identified challenges of coherence among cPPPs and the need to develop collaborations and synergies with other relevant initiatives and programmes at EU, national and regional level.

Over 80% of respondents to the Open Public Consultation (OPC) indicated that a significant contribution by future European Partnerships is 'fully needed' to achieve climate-related goals, to develop and effectively deploy technology, and for EU global competitiveness in specific sectors/domains. Views converged across all categories of respondents, including citizens, industry and academia.

¹¹ Interim evaluation of Horizon 2020, Commission Staff Working Document, SWD(2017)221 and 222 Interim evaluation of the Joint Undertakings operating under Horizon 2020 (Commission Staff Working Document, SWD(2017) 339); Evaluation of the Participation of the EU in research and development programmes undertaken by several Member States based on Article 185 of the TFEU, Commission Staff Working Document, SWD (2017)340

¹² E.g. initiatives based on Article 187 (Joint Technology Initiatives), Article 185 TFEU, Contractual Public-Private Partnerships (cPPPs), Knowledge & Innovation Communities of the European Institute of Innovation & Technology (EIT-KICs), ERA-NETs, European Joint Programmes, Joint Programming Initiatives.

The impact assessment of Horizon Europe identifies therefore the need to **rationalise the EU R&I funding landscape**, in particular with respect to partnerships, as well as to **re-orient partnerships towards more impact** and delivery on EU priorities. To address these concerns and to realise the higher ambition for European investments, Horizon Europe puts forward **a major simplification and reform for the Commission’s policy on R&I partnerships**¹³. Reflecting its pronounced systemic nature aimed at contributing to EU-wide ‘transformations’ towards the sustainability objectives, Horizon Europe indeed intends to make a more effective use of these partnerships with a **more strategic, coherent and impact-driven approach**. Key related changes that apply to all forms of European Partnerships encapsulated in Horizon Regulation are summarised in the Box below.

Box 2 Key features of the revised policy approach to R&I partnerships under Horizon Europe based on its impact assessment

- ✓ **Simpler architecture & toolbox** by streamlining 8 partnership instruments into 3 implementation forms (Co-Funded, Co-Programmed, Institutionalised), under the umbrella ‘European Partnerships’
- ✓ **More systematic and transparent approach** to selecting, implementing, monitoring, evaluating and phasing out all forms of partnerships (**criteria** for European Partnerships):
 - The selection of Partnerships is embedded in the strategic planning of Horizon Europe, thereby ensuring coherence with the EU priorities. The selection criteria require that partnerships are established with stronger ex-ante commitment and higher ambition.
 - The implementation criteria stipulate that initiatives adopt a systemic approach in achieving impacts, including broad engagement of stakeholders in agenda-setting and synergies with other relevant initiatives to promote the take-up of R&I results.
 - A harmonised monitoring & evaluation system will be implemented, and ensures that progress is analysed in the wider context of achieving Horizon Europe objectives and EU priorities.
 - All partnerships need to develop an exit strategy from Framework Programme funding. This new approach is underpinned by principles of openness, coherence and EU added value.
- ✓ **Reinforced impact orientation:**
 - Partnerships are established only if there is evidence they support achieving EU policy objectives more effectively than other Horizon Europe actions, by demonstrating a clear vision and targets (**directionality**) and corresponding long-term commitments from partners (**additionality**).
 - European Partnerships are expected to provide mechanisms – based on a concrete roadmap - to join up R&I efforts between a broad range of actors towards the development and uptake of innovative solutions in line with EU priorities, serving the economy and society, as well as scientific progress.
 - They are expected to develop close synergies with national and regional initiatives, acting as dynamic change agents, strengthening linkages within their respective ecosystems and along the value chains, as well as pooling resources and efforts towards the common EU objectives.

Under Horizon Europe, a ‘European Partnership’¹⁴ is defined as *“an initiative where the Union, prepared with early involvement of Member States and/or Associated Countries, together with private and/or public partners (such as industry, universities, research organisations, bodies with a public service mission at local, regional, national or international level or civil society organisations including foundations and NGOs), commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”*

The Regulation further specifies that European Partnerships shall adhere to the *“principles of Union added value, transparency, openness, impact within and for Europe, strong leverage effect on sufficient scale, long-term commitments of all the involved parties, flexibility in implementation, coherence, coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions.”*

¹³ Impact assessment of Horizon Europe, Commission Staff Working Document, SWD(2018)307.

¹⁴ Article 8 and Annex III of the Horizon Europe Regulation (common understanding)

1.3. Why should the EU act

1.3.1. Legal basis

Proposals for Institutionalised European Partnerships are based on:

- 1) Article 185 TFEU which allows the Union to make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; or
- 2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes.¹⁵

1.3.2. Subsidiarity

The EU should act only in areas where there is demonstrable advantage that the action at EU level is more effective than action taken at national, regional or local level. Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the EU can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas. The candidate initiatives focus on areas where there is a demonstrable value added in acting at the EU level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national activities in the same area. Overall European Partnerships find their **rationale in addressing a set of systemic failures**¹⁶:

- Their primary function is to create a platform for a strengthened **collaboration** and knowledge exchange between various actors in the European R&I system and an enhanced **coordination** of strategic research agendas and/or R&I funding programmes. They aim to address **transformational failures** to better align agendas and policies of public and private funders, pool available resources, create critical mass, avoid unnecessary duplication of efforts, and leverage sufficiently large investments where needed but hardly achievable by single countries.
- The concentration of efforts and pooling of knowledge on common priorities to solve multi-faceted societal and economic challenges is at the core of these initiatives. Specifically, enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems are among the key objectives of these instruments. In the light of Horizon Europe, the aim is to **drive system transitions and transformations towards EU priorities**.
- Especially in fast-growing technologies and sectors such as ICT, there is a need to **react to emerging opportunities** and address systemic failures such as shortage in skills or critical mass or cross-sectoral cooperation along the value chains that would hamper attainment of future European leadership and/or strategic autonomy.
- They also aim to address **market failures** predominantly to enhancing industry investments thanks to the sharing of risks.

¹⁵ Both Articles are under Title XIX of the TFEU - Research and Technological Development and Space.

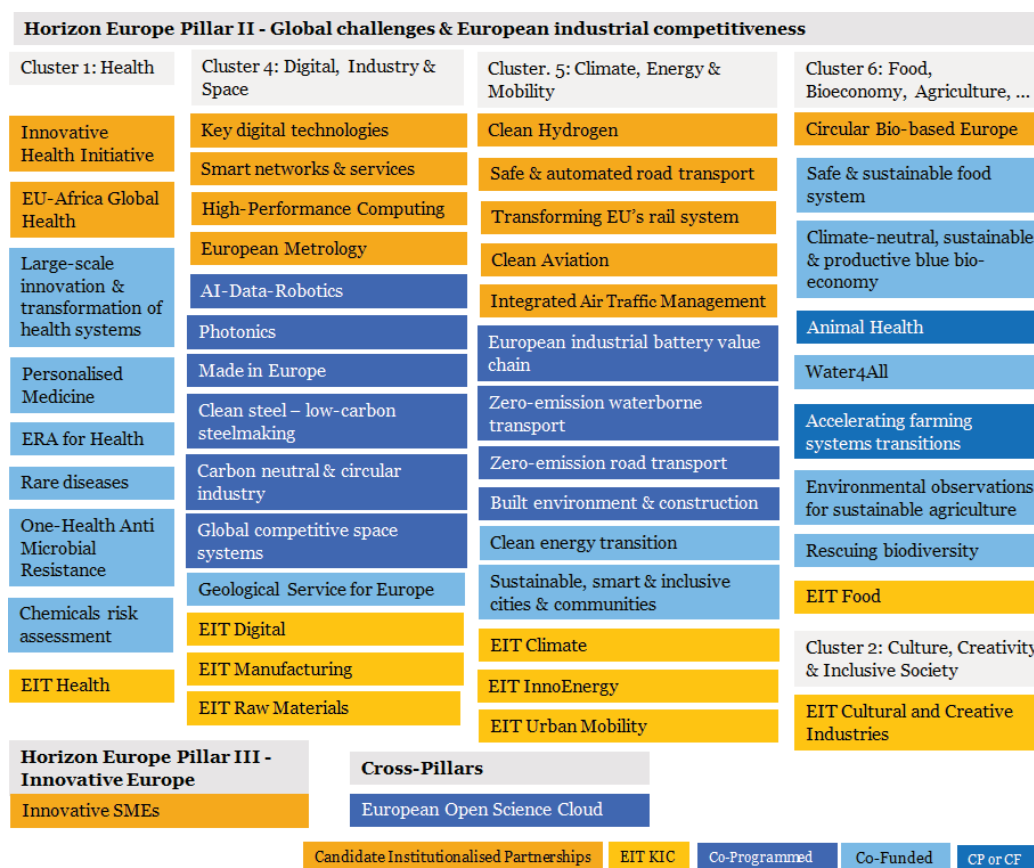

¹⁶ The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide qualitative and quantitative evidence on these points. Sections 1 and 2 of each impact assessment on candidate European Partnerships include more detail on the necessity to act at EU level in specific thematic areas.

2. THE CANDIDATE EUROPEAN PARTNERSHIPS – WHAT NEEDS TO BE DECIDED

2.1. Portfolio of candidates for Institutionalised European Partnerships

The new approach for more objective-driven and impactful European Partnerships is reflected in the way candidate Partnerships have been identified. It involved a co-design exercise aiming to better align these initiatives with societal needs and policy priorities, while broadening the range of actors involved. Taking into account the 8 areas for Institutionalised European Partnerships set out in the Horizon Europe Regulation¹⁷, a co-design exercise as part of the Strategic Planning process of Horizon Europe lead to the identification of **49 candidates for Co-funded, Co-programmed or Institutionalised European Partnerships**¹⁸. Out of these, **13 were identified as suitable candidate Institutionalised Partnerships because of their objectives and scope**¹⁹. Whilst the Co-Funded and Co-Programmed Partnerships are linked to the comitology procedure (including the adoption of the Strategic Plan and the Horizon Europe Work Programmes), Institutionalised Partnerships require the adoption of legislation and are subject to an impact assessment. The Figure below gives an overview of all candidate European Partnerships according to their primary relevance to Commission priorities for 2019-2024.

Figure 1 - Overview of the candidates for Co-Funded, Co-Programmed and Institutionalised European Partnerships according to Horizon Europe structure

Source: Technopolis group (2020)

¹⁷ Horizon Europe Regulation (common understanding), Annex Va.

¹⁸ Shadow configuration of Strategic Programme Committee for Horizon Europe. The list of candidate European Partnerships is described in “Orientations towards the Strategic Plan of Horizon Europe” - Annex 7

¹⁹ Only 12 are subject to this impact assessment, as one initiative on High Performance Computing has already been subject to an impact assessment in 2017 (SEC(2018) 47)

There are only three partnerships for which implementation as an Institutionalised Partnership under Article 185 is an option, i.e. European Metrology, the EU-Africa Global Health partnership, and Innovative SMEs. Ten partnerships are candidates for Institutionalised Partnerships under Article 187. Overall the initiatives can be categorised into ‘horizontal’ partnerships and ‘vertical’ partnerships.

The ‘horizontal’ partnerships have a central position in the overall portfolio, as they are expected to develop methodologies and technologies for application in the other priority areas, ultimately supporting European strategic autonomy in these areas as well as technological sovereignty. These ‘horizontal’ partnerships are typically proposed as Institutionalised or Co-programmed Partnerships, in addition to a number of EIT KICs, they cover mainly the digital field in addition to space, creative industries and manufacturing, but also the initiative related to Innovative SMEs. ‘Vertical’ partnerships are focused on the needs and development of specific application areas, and are primarily expected to support enhanced environmental sustainability thereby addressing Green Deal related objectives. They also deliver on policies for more people centred economy, through improved wellbeing of EU citizen and the economy, like health related candidate European Partnerships.

2.2. Assessing the necessity of a European Partnership and possible options for implementation

Horizon Europe Regulation Article 8 stipulates that Institutionalised European Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

For all candidate Institutionalised European Partnerships the options considered in this impact assessment are the same, i.e.:

- Option 0 – Baseline option – Traditional calls under the Framework Programme
- Option 1 – Co-programmed European Partnership
- Option 2 – Co-funded European Partnership
- Option 3 – Institutionalised Partnership
 - Sub-option 3a Institutionalised Partnerships based on Art 185 TFEU
 - Sub-option 3b Institutionalised Partnerships based on Art 187 TFEU

2.2.1. Option 0 - Baseline option – Traditional calls

Under this option, strategic programming for R&I in the priority area will be done through the mainstream channels of Horizon Europe. The related priorities will be implemented through **traditional calls** of Horizon Europe covering a range of actions, mainly R&I and/or innovation actions but also coordination and support actions, prizes or procurement. Most actions involve consortia of public and/or private actors in ad hoc combinations, while some actions are single actor (mono-beneficiary). There will be no dedicated implementation structure and no support other than what is foreseen in the related Horizon Europe Work Programme. This means that discontinuation costs/benefits of predecessor initiatives should be factored in for capturing the baseline situation when relevant.

Under this option, strategic planning mechanisms in the Framework Programme will allow for a high level of flexibility in the ability of traditional calls to respond to particular needs over time, building upon additional input in co-creation from stakeholders and programme committees involving Member States. The Union contribution to addressing the priority covers the full duration of the initiative, during the lifetime of Horizon Europe. Without a formal EU partnership mechanism, it is less likely that the stakeholders will develop a joint Strategic Research Agenda and commit to its implementation or agree on mutual commitments and contributions outside their participation in funded projects.

2.2.2. *European Partnerships*

Under this set of options, three different forms of implementation are assessed: Co-funded, Co-Programmed, Institutionalised European Partnerships. These have **commonalities that cannot serve as a distinguishing factor in the impact assessment process**. They are all based on agreed objectives and expected impacts and underpinned by Strategic Research and Innovation Agendas / roadmaps that are shared and committed to by all partners in the partnership. They all have to follow the same set of criteria along their lifecycle, as defined in the Horizon Europe Regulation (Annex III), including ex ante commitment from partners to mobilise and contribute resources and investments. The Union contribution is defined for the full duration of the initiative for all European Partnerships. The Horizon Europe legal act introduces few additional requirements for Institutionalised Partnerships, e.g. the need for long-term perspective, strong integration of R&I agendas, and financial contributions.

Figure 2 - Key differences in preparation and implementation of European Partnerships

Type	Legal form	Implementation
Co-Programmed	Contractual arrangement / MoU	Division of labour , whereby Union contribution is implemented through Framework programme and partners' contributions under their responsibility.
Co-Funded	Grant Agreement	Union provides co-funding for an integrated programme with distributed implementation by entities managing and/or funding national research and innovation programmes
Institutionalised based on Article 185/187 TFEU	Basic act (Council regulation, Decision by European Parliament and Council)	Integrated programme with centralised implementation

The main differences between the different forms of European Partnerships are in their preparation and in the way they function, as well as in the overall impact they can trigger. The Co-Programmed form is assessed as the simplest, and the Institutionalised the most complex to prepare and implement. The functionalities of the different form of Partnerships – compared to the baseline option – are presented in Figure 3. They relate to the types of actors Partnerships can involve and their degree of openness, the types of activities they can perform and their degree of flexibility, the degree of commitment of partners and the priority setting system, and their ability to work with their external environment (coherence), etc. These key distinguishing factors will be at the basis of the comparison of each option to determine their overall capacity to deliver what is needed at a minimised cost.

Figure 3 Overview of the functionalities provided by each form of European Partnerships, compared to the traditional calls of Horizon Europe (baseline)

Baseline: Horizon Europe calls	Option 1: Co-Programmed	Option 2: Co-Funded	Option 3a: Institutionalised Art 185	Option 3b: Institutionalised Art 187
Type and composition of actors (including openness and roles)				
<p><u>Partners:</u> N.A., no common set of actors that engage in planning and implementation</p> <p><u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules</p>	<p><u>Partners:</u> Suitable for all types: private and/or public partners, foundations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules</p>	<p><u>Partners:</u> core of national funding bodies or government-mental research organisations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> limited, according to national rules of partner countries</p>	<p><u>Partners:</u> National funding bodies or governmental research organisation</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations</p>	<p><u>Partners:</u> Suitable for all types: private and/or public partners, foundations</p> <p><u>Priority setting:</u> Driven by partners, open stakeholder consultation</p> <p><u>Participation in R&I activities:</u> fully open in line with Horizon Europe rules, but possible derogations</p>
Type and range of activities (including additionality and level of integration)				
<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions</p> <p><u>Additionality:</u> no additional activities and investments outside the funded projects</p> <p><u>Limitations:</u> No systemic approach beyond individual actions</p>	<p><u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/ societal uptake</p> <p><u>Additionality:</u> Activities/investments of partners, National funding</p> <p><u>Limitations:</u> Limited systemic approach beyond individual actions</p>	<p><u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake</p> <p><u>Additionality:</u> National funding</p> <p><u>Limitations:</u> Scale & scope depend on participating programmes, often smaller in scale</p>	<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach</p> <p><u>Additionality:</u> National funding</p>	<p><u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds).</p> <p><u>Additionality:</u> Activities/investments of partners/ national funding</p>

2.2.2.1. Option 1 - Co-programmed European Partnership

This form of European Partnership is **based upon a Memorandum of Understanding or a Contractual Arrangement** signed by the Commission and the private and/or public partners. Private partners are represented by industry associations, which also support the daily management of the partnership. This type of partnership would allow for a large degree of flexibility for the activities, partners and priorities to continuously evolve. The commitments of partners are political efforts described in the contractual arrangement and the contributions from partners are provided in kind more than financially. The priorities for the calls, proposed by the Partnership's members for integration in the Horizon Europe's Work Programmes, are subject to further input from Member States (comitology) and Commission services. The Union contribution is implemented within the executive agency managing Horizon Europe calls for research and innovation projects proposals. The full array of Horizon Europe instruments can be used, ranging from research and innovation (RIA) types of actions to coordination and support actions (CSA) and including grants, prizes, and procurement.

2.2.2.2. Option 2 – Co-funded European Partnership

The Co-funded European Partnership is **based on a Grant Agreement** between the Commission and a consortium of partners, resulting from a specific call in the Horizon Europe Work Programme. This form of implementation only allows to address public partners at its core. Typically these provide co-funding to a common programme of activities established and/or implemented by entities managing and/or funding national R&I programmes. The recipients of the EU co-funding implement the initiative under their responsibility, with national funding/resources pooled to implement the programme with co-funding from the Union. The expectation is that these entities would cover most if not all EU Member States. Calls and evaluations would be organised centrally, beneficiaries in selected projects would be funded at national level, following national funding rules.

2.2.2.3. Option 3 – Institutionalised European Partnership

This type of Partnership is the most complex and high-effort arrangement, and requires meeting additional requirements. Institutionalised European Partnership are **based on a Council Regulation (Article 187 TFEU or a Decision by the European Parliament and Council (Article 185 TFEU))** and are implemented by dedicated structures created for that purpose. These regulatory needs limit the flexibility for a change in the core objectives, partners, and/or commitments as these would require amending legislation. The basic rationale for this type of partnership is the need for a strong integration of R&I agendas in the private and/or public sectors in the EU in order to address a strategic challenge. It is therefore necessary to demonstrate that other forms of implementation would not achieve the objectives or would not generate the necessary expected impacts, and that a long-term perspective and high degree of integration is needed. For both Article 187 and 185 initiatives, contributions from partners can be in the form of financial and in-kind contributions. Eligibility for participation and funding follows by default the rules of Horizon Europe, unless a derogation is introduced in the basic act.

Option 3a - Institutionalised Partnerships based on Article 185 TFEU

Article 185 of the TFEU allows the Union to participate in programmes jointly undertaken by Member States and limits therefore the scope to **public partners** which are Member States and Associated Third Countries. This type of Institutionalised Partnership aims

therefore at reaching the greatest possible impact through the integration of national and EU funding, aligning national strategies in order to optimise the use of public resources and overcome fragmentation of the public research effort. It brings together R&I governance bodies of most if not all EU Member States (legal requirement: at least 40% of Member States) as well as Associated Third Countries that designate a legal entity (Dedicated Implementation Structure) of their choice for the implementation. By default, participation of non-associated Third Countries is not foreseen. Such participation is possible only if it is foreseen in the basic act and subject to conclusion of an international agreement.

Option 3b - Institutionalised Partnerships based on Article 187 TFEU

Article 187 of the TFEU allows the Union to set up joint undertakings or any other structure necessary for the efficient execution of EU research, technological development and demonstration programmes. This type of Institutionalised Partnership brings together a stable set of **public and private partners** with a strong commitment to taking a more integrated approach and requires the set-up of a dedicated legal entity (Union body, Joint Undertaking (JU)) that carries full responsibility for the management of the Partnership and implementation of the calls. Different configurations are possible:

- Partnerships focused on creating strategic industrial partnerships where, most often, the partner organisations are represented by one or more industry associations, or in some cases individual private partners;
- Partnerships coordinating national ministries, public funding agencies, and governmental research organisations in the Member States and Associated Countries;
- Or a combination of the two: the so-called tripartite model.

Participation of non-associated Third Countries is only possible if foreseen in the basic act and subject to conclusion of an international agreement.

2.3. Overview of the methodology adopted for the impact assessment

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines²⁰ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This also integrates **key selection criteria for European Partnerships**.

Box 2 Summary of European Partnerships selection criteria²¹

- **Effectiveness** in achieving the related objectives and impacts of the Programme;
- **Coherence** and synergies of the European Partnership within the EU R&I landscape;
- **Transparency & openness** as regards the identification of priorities and objectives and the involvement of partners & stakeholders from the entire value chain, backgrounds & disciplines;
- Ex-ante demonstration of **additionality** and **directionality**;
- Ex-ante demonstration of the partners' **long term commitment**.

2.3.1. Overview of the methodologies employed

In terms of **methods and evidence used**, the impact assessments draw on an external study covering all candidate Institutionalised European Partnerships in parallel to ensure a high level of coherence and comparability of analysis, in addition to an horizontal analysis.²² For

²⁰ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

²¹ For a comprehensive overview of the selection criteria for European Partnerships, see Annex 6.

²² Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe, Final Report, Study for the European Commission, DG Research & Innovation

all initiatives, the understanding of the overall context of the candidate institutionalised European Partnerships relied on desk research, including among others the lessons learned from previous partnerships. This was complemented by the analysis of a range of quantitative and qualitative evidence, including evaluations of past and ongoing initiatives; foresight studies; statistical analyses of Framework Programmes application and participation data, and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options, as described below. Public consultations (both open and targeted) supported the comparative assessment of the policy options. For each initiative, up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition, the analysis was informed by the results of the Open Public Consultation run between September and November 2019, the consultation of Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of initiatives.

A more detailed description of the methodology and evidence base that were mobilised, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

2.3.2. *Method for identifying the preferred option*

The first step of the assessments consisted in scoping the problems that the initiatives are expected to solve given the overall economic, technological, scientific and social context, including the lessons to be learned from past and ongoing partnerships on what worked well and less well. This supported the identification of the objectives of the initiative in the medium and long term with the underlying intervention logic – showing how to get there.

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has then been adapted to introduce “**key functionalities needed**” - making the transition between the definition of the objectives and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1). In practical terms, each option is assessed on the basis of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved (‘openness’), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options while allowing at the same time a structured comparison of the options not only as regards their effectiveness, efficiency and coherence, but also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)²³.

²³ The criterion on the ex-ante demonstration of partners' long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made compared to the baseline. Therefore, for each of these aspects the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. This includes the discontinuation costs/benefits of existing implementation structures when relevant. The policy options are then scored compared to the baseline with a + and – system with a two-point scale, to show a slightly or highly additional/lower performance compared to the baseline. A scoring of 0 of a policy option means that it would deliver as much as the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options²⁴.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach²⁵ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs and cost-savings are also taken into account²⁶. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these

²⁴ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

²⁵ For further details, see Better Regulation Toolbox # 57.

²⁶ Discontinuation costs will bear winding down and social discontinuation costs and vary depending on e.g. the number of full-time-equivalent (FTEs) staff concerned, the type of contract (staff category and duration) and applicable rules on termination (e.g. contracts under Belgian law or other). If buildings are being rented, the cost of rental termination also apply. As rental contracts are normally tied to the expected duration of the current initiatives, these termination costs are likely to be very limited. In parallel, there would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is developed further in the individual efficiency assessments.

average static costs would have been misleading, because of the different features and needs of each candidate initiative.²⁷ The table shows the overall administrative, operational and coordination costs of the various options. These costs are then put into context in the impact assessments to reflect the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution (cost-efficiency):

- The costs related to the baseline scenario (traditional calls under Horizon Europe) are pre-dominantly the costs of implementing the respective Union contribution via calls and project, managed by the executive agencies (around 4%, efficiency of 96% for the overall investment).
- For a Co-Programmed partnership the costs of preparation and implementation increase only marginally compared to the baseline (<1%), but lead to an additional R&I investment of at least the same amount than the Union contribution²⁸ (efficiency of 98% for the overall investment).
- For a Co-Funded partnership the additional R&I investment by Member States accounts for 2,3 times the Union contribution²⁹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the national programmes, can be estimated at 6% of the Union contribution (efficiency of 98% related to the overall investment).
- For an Article 185 initiative the additional R&I investment by Member States is equal to the Union contribution³⁰. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 7% of the Union contribution (efficiency of 96% related to the overall investment).
- For an Article 187 initiative the additional R&I investment by partners is equal to the Union contribution³¹. The additional costs compared to the baseline of preparing and implementing the partnership, including the management of the Union contribution implemented by the dedicated implementation structure, can be estimated at 9% of the Union contribution (efficiency of 94% related to the overall investment).

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0		↑↑		
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0		↑↑		
Ex-ante Impact Assessment for partnership		0		↑↑↑	
Preparation of EC proposal and negotiation		0		↑↑↑	

²⁷ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

²⁸ Minimum contributions from partners equal to the Union contribution

²⁹ Based on the default funding rate for programme co-fund actions of 30%, partners contribute with 70% of the total investment.

³⁰ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

³¹ Based on the minimum requirement in the legal basis that partners contribute at least 50% of the budget.

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b -Art. 187
Running costs (Annual cycle of implementation)					
Annual Work Programme preparation	0		↑		
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC			0		↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

The cost categories estimated for the common model are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**)³². In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

For the **identification of the preferred option**, the scorecard analysis builds a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

As a last step, the alignment of the preferred option with key criteria for the selection of European Partnerships is described, reflecting the outcomes of the ‘**necessity test**’.³³ The monitoring and evaluation arrangements are concluding the assessment, with an identification of the key indicators to track progress towards the objectives over time.

2.4. Horizontal perspective on candidate Institutionalised European Partnerships

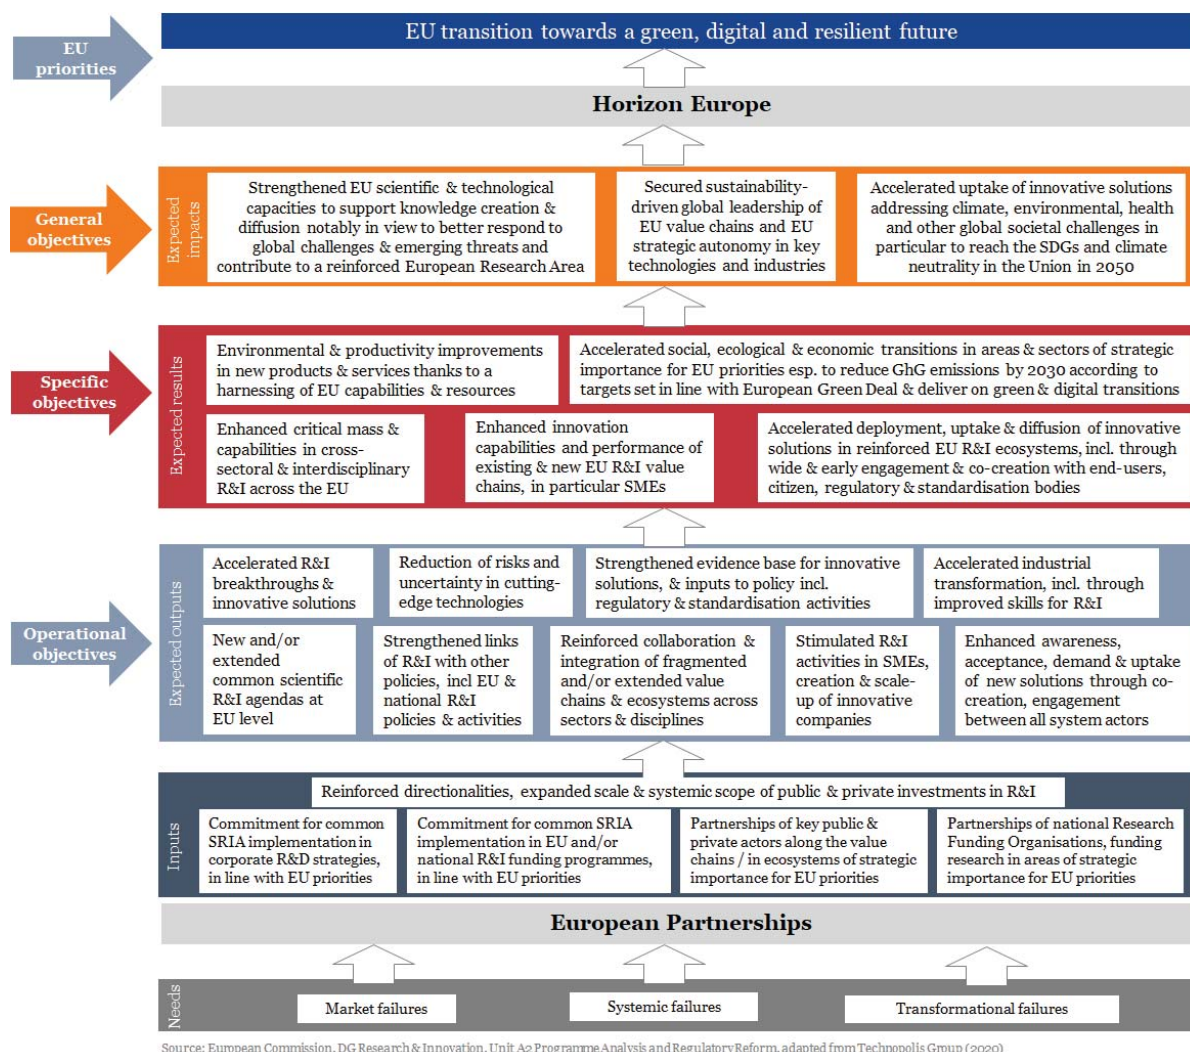

2.4.1. Overall impact orientation, coherence and efficiency needs

The consolidated **intervention logic** for the set of candidate Institutionalised European Partnerships in the Figure below builds upon the objectives as reported in the individual impact assessments.

³² More details on the methodology can be found in Annex 4.

³³ Certain aspects of the selection criteria will be further addressed/ developed at later stages, notably in the context of preparing basic acts (e.g. Openness and Transparency; Coherence and Synergies), in the Strategic Research and Innovation Agendas (e.g. Directionality and Additionality), and by collecting formal commitments (Ex-ante demonstration of partners’ long-term commitment).

Figure 5 – Overall intervention logic of the European Partnerships under Horizon Europe

When analysed as a package the 12 candidate Institutionalised European Partnerships are expected to support the achievement of the European policy priorities targeted by Horizon Europe by pursuing the following joint general objectives:

- Strengthening and integrating EU scientific and technological capacities to support knowledge creation and diffusion notably in view to better respond to global challenges and emerging threats and contribute to a reinforced European Research Area;
- Securing sustainability-driven global leadership of EU value chains and EU strategic autonomy in key technologies and industries; and
- Accelerate the uptake of innovative solutions addressing climate, environmental, health and other global societal challenges contributing to Union strategic priorities, in particular to reach the Sustainable Development Goals and climate neutrality in the Union in 2050.

In terms of specific objectives, they jointly aim to:

- Enhance the critical mass and scientific capabilities in cross-sectoral and interdisciplinary research and innovation across the Union;
- Accelerate the social, ecological and economic transitions in areas and sectors of strategic importance for Union priorities, in particular to reduce greenhouse gas

emissions by 2030 according to the targets set in line with the European Green Deal, and deliver on the green and digital transition;

- c) Enhance the innovation capabilities and performance of existing and new European research and innovation value chains, in particular SMEs;
- d) Accelerate the deployment, uptake and diffusion of innovative solutions in reinforced European R&I ecosystems, including through wide and early engagement and co-creation with end-users, citizen and regulatory and standardisation bodies;
- e) Deliver environmental and productivity improvements in new products and services thanks to a harnessing of EU capabilities and resources.

In terms of their operations, taking an horizontal perspective on all initiatives allows for the identification of further possible collective efficiency and coherence gains for more impact:

- **Coherence for impact:** The extent and speed by which the expected results and impacts will be reached, will depend on the scale of the R&I efforts triggered, the profile of the partners involved, the strength of their commitments, and the scope of the R&I activities funded. To be fully effective it comes out clearly that future partnerships need to operate over their whole life cycle in full coherence with their environment, including potential end users, regulators and standardisation bodies. This relates also to the alignment with relevant EU, national or regional policies and synergies with R&I programmes. This needs to be factored in as of the design stage to ensure a wide take-up and/or deployment of the solutions developed, including their interoperability.
- **Collaboration for impact:** Effectiveness could also be improved collectively through enhanced cross-disciplinary and cross-sectoral collaboration and an improved integration of value chains and ecosystems. An adequate governance structure appears in particular necessary to ensure cross-fertilisation between all European Partnerships. This applies not only to initiatives where similar R&I topics are covered and/or the same stakeholders involved or targeted, but also to the interconnections needed between the ‘thematic’ and the ‘vertical’ Partnerships, as these are expected to develop methodologies and technologies for application in EU priority areas. Already at very early stages of preparing new initiatives, Strategic Research and Innovation Agendas and roadmaps need to be aligned, particularly for partnerships that develop enabling technologies that are needed in other Partnerships. The goal should be to achieve greater impacts jointly in light of common challenges.
- **Efficiency for impact:** Potential efficiency gains could also be achieved by joining up the operational functions of Joint Undertakings that do not have a strong context dependency and providing them through a common back-office³⁴. A number of operational activities of the Joint Undertakings are of a technical or administrative nature (e.g. financial management of contracts), or procured from external service providers (e.g. IT, communication activities, recruitment services, auditing) by each Joint Undertaking separately. If better streamlined this could create a win-win situation for all partners leading to better harmonization, economies of scales, and less complexity in supervision and support by the Commission services.

³⁴ See Annex 6 for an overview of key functions/roles that could be provided by a common back office.

2.4.2. *Analysis of coherence of the overall portfolio of candidate initiatives at the thematic level*

Looking at the coherence of the set of initiatives at the thematic level, the “**digital centric**” initiatives have a strong focus on supporting the digital competitiveness of the EU ecosystem. Their activities are expected to improve alignment and coordination with Member States and industry for the development of world-competitive EU strategic digital technology value chains and associated expertise. Addressing the Key Digital Technologies, the 5G and 6G connectivity needs as part of a Smart Networks and Services initiative and the underlying supercomputing capacities through a European High Performance Computing initiative present potential for synergies that can be addressed through cooperative actions (e.g. joint calls, coordinated support activities, etc.). They may as well profit from and contribute to Partnerships envisaged for Photonics, AI, data, robotics, Global competitive space system and Made in Europe, together with the EIT Digital. Synergies between these initiatives and several programmes (Digital Europe and Connecting Europe as well as cohesion programmes) are needed in areas where EU industry has to develop leadership and competitiveness in the global digital economy. They are expected to impact critical value chains including on sectors where digital is a strong enabler of transformation (health, industrial manufacturing, mobility/transport, etc.).

The **transport** sector face systemic changes linked to decarbonisation and digitalisation. Large scale R&I actions are needed to prepare the transition of these complex sectors to provide clean, safer, digital and economically viable services for citizens and businesses. Past decades have shown that developing and implementing change is difficult in transport due to its systemic nature, many stakeholders involved, long planning cycles and large investments needed. A systemic change of the air traffic network through an Integrated Air Traffic Management initiative should ensure safety and sustainability of aviation, while a Clean Aviation initiative should focus on the competitiveness of tomorrow’s clean aircrafts made in Europe. The initiative for Transforming Europe’s rail system would comprehensively address the rail sector to make it a cornerstone in tomorrow’s clean and efficient door-to-door transport services, affordable for every citizen as well as the most climate-friendly mode of transport for freight. Connected and Automated Mobility is the future of road transport, but Europe is threatened to fall behind other global regions with strong players and large harmonised markets. The initiative Safe and Automated Road Transport would bring stakeholders together, creating joint momentum in digitalising road transport and developing new user-based services. Stronger links and joint actions will be established between initiatives to enable common progress wherever possible. The Clean Hydrogen initiative would be fundamental to that regard. Synergies would also be sought with partnerships driving the digital technological developments.

To deliver a deep decarbonisation of highly emitting industrial sectors such as the steel, transport and chemical industries would require the production, distribution and storage of **hydrogen** at scale. The candidate hydrogen initiative would have a central positioning in terms of providing solutions to the challenges for sustainable mobility and energy, but also is expected to operate in synergies with other industry related initiatives. The initiative would interact in particular with initiatives on the zero emission road and water transport, transforming Europe’s railway system, clean aviation, batteries, circular industry, clean steel and built environment partnerships. There are many opportunities for collaboration for the delivery and end-use of hydrogen. However, the Clean Hydrogen initiative would be the only partnership focused on addressing hydrogen production technologies.

Metrology, the science of measurement, is an enabler across all domains of R&I. It supports the monitoring of the Emissions Trading System, smart grids and pollution, but also

contributes to meeting demands for measurement techniques from emerging digital technologies and applications. More generally, emerging technologies across a wide range of fields from biotechnologies, new materials, health diagnostics or low carbon technologies are giving rise to demands requiring a world-leading EU metrology system.

The initiative for a **Circular Bio-based Europe** is intended to solve a shortage of industry investments in the development of bio-based products whose markets do not have yet certain long-term prospects. The **Innovative Health Initiative** and **EU-Africa Global Health** address the lack of investments in the development of solutions to specific health challenges. The initiative on **Innovative SMEs** supports innovation-driven SMEs in participating in international, collaborative R&I projects with other innovative firms and research-intensive partners. As a horizontal initiative it is expected to help innovative SMEs to grow and to be successfully embedded in global value chains by developing methodologies and technologies for potential application in the other partnership areas or further development by the instruments of the European Innovation Council.

The description of the interconnections between all initiatives for each Horizon Europe cluster is provided in the policy context of each impact assessment and further assessed in the coherence assessment for each option.

1. INTRODUCTION: THE POLITICAL AND LEGAL CONTEXT

Hydrogen is the most abundant element in the universe, making up more than 90 percent of all of the atoms. However, nature does not provide hydrogen in its elemental form. Hydrogen can be derived from water and other chemical compounds. Electricity or heat is needed to liberate hydrogen from the chemical compound. Among its many uses, researchers have been studying hydrogen with great interest because of its potential as a sustainable energy source. While hydrogen is a clean fuel, with no emissions at all, it is still more expensive than other energy sources, and its production is not pollution free as most of the hydrogen currently produced comes from natural gas, a process that generates carbon dioxide (CO₂). Researchers have therefore been looking for alternative and more environmentally friendly ways of producing ‘**clean hydrogen**’ that would ideally eliminate CO₂ emissions from the process. Hydrogen, as an energy carrier, is progressively viewed as a means to increase the share of renewables in European energy markets, to store and transport large amounts of electricity and to provide energy for sectors otherwise difficult to decarbonise. Hydrogen enables sector integration between the electricity system and industry and between buildings and transport. The focus on hydrogen applications has evolved gradually and in the future will increasingly centre on clean hydrogen. Due to the flexibility and versatility of hydrogen and a multitude of hydrogen end-use applications, deployment of clean hydrogen at scale would support the targeted transition to carbon neutrality by 2050 in the EU. This document focuses on assessing the most effective, efficient and coherent way of implementing an initiative which would focus on joint European research and innovation activities on Clean Hydrogen under Horizon Europe.

1.1. Emerging challenges in the field

Achieving a climate-neutral EU economy by 2050 calls for the EU to ensure a deep decarbonisation of highly emitting industrial sectors such as steel, transport and chemical industries (refineries and fertilizers plants). That would require production, distribution and storage of hydrogen at scale. Hydrogen applications have progressed significantly over the past decade.^{35,36} Several important technologies have been developed from low technology readiness levels to market-readiness, with the scope of hydrogen applications continuously broadening.^{37,38,39,40,41}

⁴¹ Power Engineering International (2019), Hydrogen: The hope for ‘hard-to-decarbonise’ sectors – available at <https://www.powerengineeringint.com/2019/09/26/hydrogen-the-hope-for-hard-to-decarbonise-sectors/>

Nevertheless, the sector is still in a pre-deployment stage and massive cost reductions across the entire supply chain are necessary to enable mass commercialisation to meet decarbonisation needs at energy system level. In order to achieve these cost reductions, the sector must tackle problems such as market failure for first movers and fragmentation among players and lack of critical mass. By virtue of hydrogen's versatility, the 'sector' is spread over various applications in energy, transport and industry, but also over actors and countries.

Developing the hydrogen economy requires investments in hydrogen generation and end-use equipment in sectors that are difficult to decarbonize by other means, such as heavy duty transport. It will also require investments in hydrogen storage, transportation, and distribution infrastructure – whose absence is currently stalling the rollout of market-ready hydrogen applications.^{42,43} Large scale integrated hydrogen generation systems will be developed (e.g. clean hydrogen from photovoltaics and wind).

At the same time, continuous research and development will be required to ensure that hydrogen technologies are technically improved, highly efficient, and as competitive as possible.^{44,45,46} The scope of hydrogen applications is increasing from its present focus on transport, fuel cells and electrolyzers, and is expanding to include the energy sector (power, heating and gas), industry and new transport applications (maritime, aviation, rail, heavy transport).⁴⁷ With the constant emergence of new applications, the supply chain becomes more complex and continuous improvements⁴⁸ (new materials⁴⁹, efficiency, reliability, lifetime⁵⁰, cost⁵¹) are still needed for all applications.⁵²

The lack of a regulatory framework supporting and governing the use of hydrogen applications adds to these challenges.⁵³ For many years, hydrogen applications were not

⁴⁷ The scope expansion has been addressed in the frame of the structured consultation of Member States fiche for Clean Hydrogen, June 2019

⁴⁸ The Appendix: Analytical report on the Strategic Value Chain (SVC) on Hydrogen technologies and systems in the frame of the Strategic Forum on IPCEI (called the “IPCEI Appendix”), points out the special techno-economic challenges of reducing the cost, increasing the efficiency and reducing the use of Critical Raw Materials (from FCH JU lists) (p 29)

⁴⁹ The “IPCEI Appendix” addresses, as example, the development and qualification of new materials to continue improving high pressure hydrogen storage (p 10)

⁵⁰ Example of buses lifetime addressed in the “Competitiveness Analysis” (p 67)

⁵¹ The “IPCEI Appendix” points out the cost of producing hydrogen should be reduced (p 13), FCEV should cost similar to electrical vehicles (p14), technologies cost reduction is also a question of competitiveness with other regions especially Asian competitors (p28). The “Competitiveness Analysis” illustrates cost decrease expectations by 2030, for many different applications, depending on mass production (p 48)

⁵² See Annex 6 for general information on the hydrogen sector.

⁵³ European Commission and Hydrogen Europe (2019), Hydrogen for Climate Action: How to kick start the EU Hydrogen Industry to achieve the EU climate goals? –available at

technologically advanced enough to motivate the EU to develop and adopt hydrogen legislation. However, policy guidelines at local, national and EU-levels are increasingly necessary to enable hydrogen's market entry on a large scale.^{54,55,56}

Finally the international dimension of hydrogen deployment and upscaling of production at global level has to be addressed. For example, the import of cheap clean hydrogen from wind and solar energy, produced outside of Europe, might become more important in the mid-term. These deployments urge the setting up of international standards, the development of the required infrastructure and developing a methodology on defining emissions from each unit of hydrogen produced.

1.2. EU relative positioning in the field

Europe is currently in an excellent position to achieve a significant level of penetration of hydrogen and fuel cell technologies over the next decade, at a level that can: (a) prove that hydrogen can fulfil a key role towards fighting climate change and improving public health; (b) act as a central pillar in decarbonisation and elimination of other harmful emissions of everyday activities; and (c) positively impacting the economy thanks to a broad and competitive supply chain that keeps Europe in a leading position and creates a new wave of highly skilled jobs.

The latter was recognized by the **Strategic Forum for Important Projects of Common European Interest (IPCEI⁵⁷)** which identified six key strategic value chains⁵⁸ of specific importance for EU's industries and competitiveness among which an **"Hydrogen technologies and systems"** value-chain. It is worth mentioning that European industry is active in all areas of the hydrogen economy along the whole value chain⁵⁹. To name a few:

- **In Clean hydrogen production** firstly, through electrolysis technologies.⁶⁰ The EU is a scientific and industrial leader in today's global electrolysis industry, with competitors in China, Japan and the US less active.⁶¹ Second, through other technologies (incl. Steam

https://static1.squarespace.com/static/5d3f0387728026000121b2a2/t/5d9f23c486e0ee312c6380a7/1570710475026/Framework_H2+for+Climate+Action_final.pdf

Methane Reforming with Carbon Capture Storage/Use⁶²) which could be useful in a transition phase, although not all of them are necessarily relevant for the proposed Clean Hydrogen initiative, but rather for other funding instruments.

- **In Hydrogen distribution and storage:**⁶³ EU industry and particularly EU SMEs are at the forefront of hydrogen handling and logistics with many leading companies focusing on multiple applications and technologies, including hydrogen refuelling stations (HRS), liquefaction facilities, and ammonia and methanol conversion plants.⁶⁴
- **In Hydrogen end use in transport where** hydrogen and fuel cells can play an important role fostering a low-carbon road transport system.⁶⁵ In particular, hydrogen is envisioned to play a vital decarbonisation role in long-distance transport (e.g. for long-haul heavy goods vehicles and coaches), in buses and truck fleets, in aviation, in rail transport, and in the maritime sector.⁶⁶ Although Directive 2014/94/EU “on the deployment of alternative fuels infrastructure” does not set out any obligation for Member States to indicate an appropriate number of publicly accessible hydrogen supply points in their national policy frameworks (NPFs), hydrogen is included in 14 NPFs and some Member States, for example Germany, have defined ambitious targets for hydrogen infrastructure.⁶⁷
- **In Hydrogen end use** – there are solutions for hydrogen to decarbonise the natural gas grid through the blending & upgrade of natural gas to a pure hydrogen grid and then supplying heating and power for buildings. In the European decarbonisation context, these solutions may be appropriate in certain market segments or in specific conditions, e.g. islands; power generation (providing seasonal storage on renewable electricity); hydrogen replacing natural gas for process heat in industry.
- **In Hydrogen end uses in industry:** Clean hydrogen can be supplied as industrial feedstock. Potential end-use sectors for hydrogen in industry include steel and iron manufacturers. Main current end-users such as refineries, ammonia plants and other chemical manufacturers could be supplied with clean hydrogen. Organisations involved with the multiple demonstration projects ongoing in Europe will soon have unrivalled expertise in the integration of clean hydrogen as a feedstock for industry.^{68,69,70}

⁶⁶ Fuel Cell and Hydrogen 2 Joint Undertaking (2019), Hydrogen Roadmap Europe, available at <https://www.fch.europa.eu/news/hydrogen-roadmap-europe-sustainable-pathway-european-energy-transition>

⁶⁷ The Commission Delegated Regulation (EU) 2019/1745 of 13 August 2019 “supplementing and amending Directive 2014/94/EU amends the technical specifications for hydrogen refuelling points for motor vehicles set out in the Annex II of the Directive. The amended standards will apply from 12 November 2021.

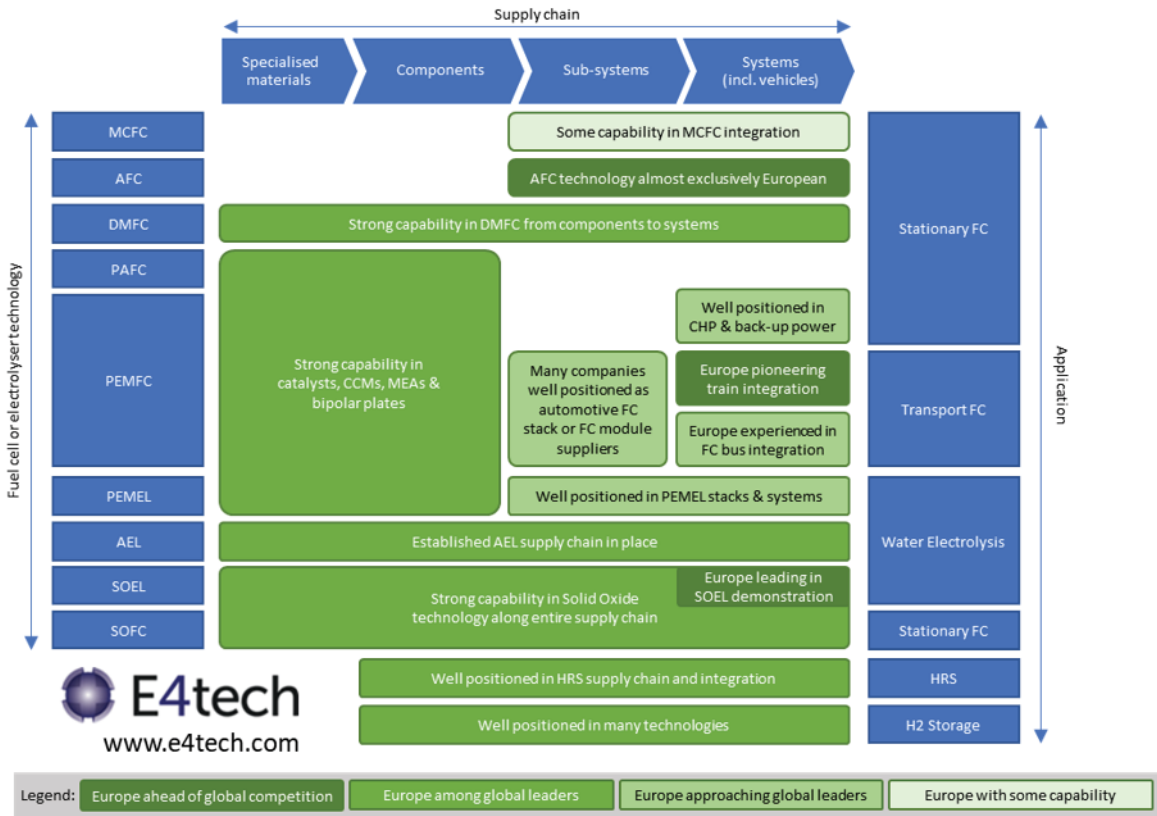

⁶⁸ e.g. the H2FUTURE project is injecting green hydrogen into steel production, thereby eliminating greenhouse gas emissions that would normally ensue. Demonstrating that even energy-dependent sectors can rely on this technology will make for increasingly green industrial production (FCH JU success stories)

⁶⁹ Refhyne, launched in 2018, is on course to build the largest hydrogen electrolysis plant of its kind in the world, with a capacity of 10MW, at the Rhineland refinery in Germany (FCH JU success stories)

⁷⁰ In 2016, SSAB, LKAB and Vattenfall formed a joint venture project with the aim of replacing coking coal in ore-based steel making with H₂. In 2018, a pilot plant was planned and designed in Lulea and the Norbotten iron ore fields to provide a testing facility for green H₂(produced by electrolysis) to be used as a reducing agent in steel-making. Project partners state that using this production method could make steel (the Technology Roadmap, Hydrogen Europe)

At global level, Europe is confronted with fierce competition from countries which are also promoting the use of hydrogen as a clean and alternative energy vector and have developed hydrogen strategies and policies. This is the case for the United States, Japan, Korea and China which are all developing large R&I programmes addressing similar segments of the Hydrogen value-chain mentioned above. However, one can notice from Figure 6 below that Europe has a relatively privileged position being ahead of global competition or among the global leaders in a few segments of the hydrogen value-chain.

Figure 6 – European global leadership in various hydrogen technologies⁷¹

In terms of R&I performance and in particular - publishing⁷², Europe is showing strong leadership in publishing peer reviewed papers concerning electrolysis technologies (884 papers vs 1,568 papers from the rest of the world) as well as non-electrolysis production methods (1,549 papers vs 4,266). As regards fuel cell technologies, Europe (with 4,971 papers) is competing with the United States for the second position against Asia (10,493 papers). Asia's strong publications record in this field is often using their national language and publishing in national journals.

Overall, Europe is exceptionally active in PEM fuel cells with namely 2,780 papers and 448 patents filed covering this topic. Concerning patenting, Asia is the frontrunner compared to the rest of the world. Among the various sectors, Europe is clearly advancing well in Solid Oxide and PEM Electrolysis technologies, with more than 500 patents filed.

⁷¹ The main trends are coming from the study on Value Chain and Manufacturing Competitiveness Analysis for Hydrogen and Fuel Cells Technologies, Evidence Report, E4tech (UK) Ltd for FCH 2 JU in partnership with Ecorys and Strategic Analysis Inc, oct 2018. These are completed by the Hydrogen, enabling a zero emission Europe, technology roadmaps full pack, Sept 2018, Hydrogen Europe

Box 3 Support for the field in the previous Framework Programmes – key strengths & weaknesses identified

What was/is being done with EU research and innovation funding until now

Dedicated R&I activities related to hydrogen applications have been supported since 2008. This covers traditional (collaborative) projects but also support provided through the Fuel Cell and Hydrogen Joint Undertakings (FCH JU and FCH 2 JU) under FP7 and Horizon 2020, which cover all stages/fields of the hydrogen value chain described above.

The first FCH JU was set up in 2008 as a public-private partnership between the EU, industry and the research community with a budget of EUR 470 million. The objective was to promote coordination and collaboration across Europe's fragmented FCH sector, to pool resources and to develop a long term, integrated, pan-European research and innovation agenda.

The programme entered its second phase, with FCH 2 JU, in Horizon 2020.

FCH 2 JU is a public-private partnership with 3 members: the industry grouping Hydrogen Europe, the research grouping Hydrogen Europe Research and the European Commission. The focus is on accelerating the commercialisation of fuel cells and hydrogen technologies to ensure a world leading, competitive European FCH industry while increasing jobs. The objectives of FCH 2 JU, organised around the energy and transport, pillars are the following:

- Clean transport: Reduce fuel cell system costs for transport applications
- Green hydrogen production: Increase efficiency and reduce costs of hydrogen production, mainly from water electrolysis and renewables
- Heat & electricity production: Increase fuel cell efficiency and lifetime
- Hydrogen storage for grid balancing: Demonstrate on a large-scale hydrogen's capacity to harness power from renewables and support its integration into the energy system
- Minimal use of critical raw materials: Reduce platinum loading

What has or is being achieved so far

The main achievements of the FCH JU and FCH 2 JU are that they contributed⁷³ to structure and mobilise an otherwise fragmented landscape of different sectors and industries by convincing competing or different, unrelated stakeholders to work together towards clear objectives⁷⁴, and that they developed successful mechanisms for fostering continued technological innovation.

For example, FCH 2 JU enabled key European fuel cell stack manufacturers such as Nedstack, Proton-motor, Powercell, Symbio and Elringklinger to nurture and to kick start competitive industrial-scale production of automotive fuel cell stacks in the EU, allowing Europe to compete with other regions of the world. FCH 2 JU was also instrumental in scaling up electrolysis technology, through recent projects such as REFHYNE⁷⁵ and

⁷³ Commission Staff Working Document - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, {SWD (2017) 339 final}

⁷⁴ The objectives of the FCH JU, as laid down in its founding regulation.

⁷⁵ <https://refhyne.eu/>

DJEWELS⁷⁶. However, further improvements are still needed in terms of costs, efficiency, reliability, while reaching the Giga-Watt scale. The FCH JU is also supporting initiatives at regional level, such as the HEAVENN project⁷⁷, which can help create local/regional value chains and demonstrate the role of hydrogen to integrate renewables in the energy system and decarbonise sectors that lag behind like transport and industry.

What are the key areas for improvement & unmet challenges?

However, a number of systemic challenges already identified in the interim evaluation of FCH 2 JU⁷⁸ risk derailing the progress already achieved and will have to be better addressed in a new Clean Hydrogen Initiative. These challenges include:

- i) Pre-Normative Research (PNR) and even though not directly addressed in the proposed initiative, Regulation, Codes and Standards barriers, most notably the lack of technical regulations and/or accepted standards which prevent large scale, international deployment of standardised products;
- ii) Funding concentration, and the need to ensure that the current geographical distribution of projects supported by the present JU is not reinforced by any lack of information/openness/transparency to entities from countries where participation is low, in particular EU13;
- iii) The involvement of Member States and in particular the role of the State Representative Group which is not as effective as it should be;
- iv) Knowledge management, open data and knowledge transfer, human resource developments and trainings are all necessary components to ensure that deployment takes place consistently in different sectors of the economy and finally,
- v) The need for more attention to safety of FCH technologies necessary to building the confidence needed for widespread take-up. The relatively few projects introducing hydrogen in new settings (in buses, homes or in refuelling stations alongside conventional fuels) has not allowed products to be rolled-out commercially.

1.3. EU policy context beyond 2021

Hydrogen has been a field of interest for the EU since a few decades. However, the political context has evolved very significantly in the last five years with all Member States of the EU having signed and ratified the Conference of the Parties (COP21) Paris agreement and the European Union committing to contribute to delivering the Sustainable Development Goals (SDGs).

In 2018, the European Commission published “**A Clean Planet for all**”, the strategic long-term vision of the Commission for a prosperous, modern, competitive and climate-neutral economy by 2050. The communication sets out a clear vision of how to achieve **climate neutrality by 2050**, recognising that “the role of hydrogen is likely to become more

⁷⁶ <https://www.fch.europa.eu/news/fch-ju-funds-pioneering-green-hydrogen-project>

⁷⁷ <https://www.fch.europa.eu/page/energy#HEAVENN>

⁷⁸ Commission Staff Working Document - Interim Evaluation of the Joint Undertakings operating under Horizon 2020, {SWD (2017) 339 final}

prominent in a fully decarbonised energy system,” and including hydrogen and fuel cells in its list of “transformational carbon-neutral solutions that EU research should focus on.”⁷⁹

At the end 2019, the Commission presented its new priorities for the coming years, including the European Green Deal, a new growth strategy that aims to transform the EU into a fair and prosperous society, with a modern, resource-efficient and competitive economy, where there are no net emissions of greenhouse gases in 2050 and where economic growth is decoupled from resource use. It states that EU industry needs ‘climate and resource frontrunners’ to develop the first commercial applications of breakthrough technologies in key industrial sectors by 2030. Priority areas include **clean hydrogen, fuel cells** and other alternative fuels, energy storage, and carbon capture, storage and utilisation. In this context, Hydrogen is also prominent in the Strategies and Communications for Hydrogen⁸⁰ for Energy System Integration⁸¹ as well as the launch of the European Clean Hydrogen Alliance. The European Clean Hydrogen Alliance⁸² aims to bring all stakeholders together and identify technology needs, investment opportunities, regulatory barriers and enablers to build a clean hydrogen ecosystem in the EU. On 28 May the Communication on "Europe's moment: Repair and Prepare for the Next Generation", was adopted which highlights in particular the important role of hydrogen in the EU economic recovery plan. The second pillar of this proposal is particularly relevant and includes clean hydrogen among the clean technologies and value chains which need to be supported and strengthened.

Actions are starting to enforce climate policies that would trigger intensive/deep decarbonisation in heavy industry and heavy transport sectors in which clean hydrogen applications represent some of the only feasible carbon-reduction solutions.⁸³

In Horizon Europe, Hydrogen is part of the research and innovation activities funded under the Pillar II, Cluster: Climate, Energy and Mobility which aims at contributing to the attainment of at least three of the six main ambitions for Europe: ‘A European Green Deal’, ‘A people-centred economy’ and ‘A Digital Europe’. It is supportive of several of the Sustainable Development Goals, particularly SDG7 (Affordable and clean energy), Climate Actions (SDG13) and Sustainable Cities and Communities (SDG11). The long term targeted impact of this cluster corresponds directly to the main objectives of fostering climate action, while at the same time improving the sustainability, security and competitiveness of the energy and transport industry, as well as the quality of the services that these sectors bring to citizens and society at large. The hydrogen economy addresses many different technological solutions and applications concerning different actors and linkages to various sectors. Adequate collaboration and connection with the relevant sectors are therefore required along the whole value chain.

⁷⁹ European Commission (2018), A Clean Planet for all: A European strategic long-term vision for a prosperous, modern, competitive and climate neutral economy, Communication from the Commission to the European Parliament, the European Council, the Council, The European Economic and Social Committee, The Committee of the Regions and the European Investment Bank COM(2018)773, available at <https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX:52018DC0773>

In addition to an initiative for Clean Hydrogen, other initiatives are put forward as possible partnerships under Horizon Europe. Potential initiatives in the Climate, Energy and Mobility cluster are shown in Figure 7. This shows not only the horizontal positioning of the potential Clean Hydrogen initiative, in terms of providing solutions to the challenges for sustainable mobility and energy, but also opportunities for synergies with a wide set of initiatives in other clusters (especially the digital and industry cluster). In addition, an initiative related to Clean Hydrogen would need to also link with the maritime sector, the power (especially the renewable energy sector), and the gas sector (especially gas grid operators). Strong collaboration would be needed between these initiatives to ensure proper integration of technologies into applications aiming to decarbonize the concerned sectors. It is important to note that some of these initiatives would probably not succeed or have the expected impact without an ambitious Clean Hydrogen Initiative able to supply hydrogen at scale.

Synergies with other EU programmes and networks which address hydrogen would also be needed, in particular: the **European Energy Research Alliance (EERA)** and its “Joint Programme on Fuel Cells and Hydrogen”⁸⁴; the High Level Expert Group on Energy-Intensive Industries which developed the **Industrial Transformation Master Plan for climate-neutral industry by 2050**⁸⁵ highlighting the key role of hydrogen; funds and financing mechanisms that would support innovation and industrialisation and would help to bridge the “valley of death”, in particular the **Connecting European Facility (CEF)**⁸⁶, the **ETS Innovation Fund**, and the **European Investment Bank**, with loans provided by InnovFin EDP.

⁸⁶ EC (2018), Proposal for a Regulation of the European Parliament and of the Council establishing the Connecting Europe Facility, COM(2018) 438 final

2. PROBLEM DEFINITION

2.1. What is/are the problems?

Given the scale of the challenges ahead for a sustainable energy transition, the current scientific, technological and economic positioning of Europe in the field, and the overarching EU policy context, a set of problems have been identified where EU research and innovation in the field of Clean Hydrogen would have a specific role to play (see Figure 8).

Figure 8: Problem tree behind an initiative for European research and innovation on Clean Hydrogen

The part in yellow is not within the scope of the proposed Clean Hydrogen initiative. Important to mention is that the initiative seeks to address in particular **research aspects related to production, distribution, infrastructure and storage of hydrogen**.

2.1.1. *The clean hydrogen value-chain not optimized to cope with emerging clean hydrogen applications limiting their market readiness.*

Hydrogen applications have been developed in the FCH 2 JU to different levels of technological readiness. Those at higher Technology Readiness Levels (TRL) – including stationary fuel cells, light FCEVs, fuel cell buses and small scale electrolysers – are basically ready for market deployment; however, they remain comparatively more expensive than competitor technologies.^{87,88,89} Substantial R&I effort is still needed to improve their efficiency, cost, durability and manufacturability.⁹⁰

⁸⁷ Financial Times (2019), Hydrogen could help decarbonise the global economy – available at <https://www.ft.com/content/959d08e2-a899-11e9-984c-fac8325aaa04>

⁸⁸ World Energy Council (2018), Hydrogen an enabler of the Grand Transition: Future Energy Leader position paper – available at https://www.worldenergy.org/assets/downloads/1Hydrogen-an-enabler-of-the-Grand-Transition_FEL_WEC_2018_Final.pdf

To develop an efficient clean hydrogen ecosystem, hydrogen will need to be produced in the power sector mainly from renewable energy sources, distributed via the gas-transmission sector or via the transport sector, and used in the transport, industry, and building sectors.^{91,92} However, it is difficult to motivate actors across these traditionally independent sectors to work together on collaborative R&I projects and develop strong collaborative frameworks.^{93,94}

Scientific advancement for key hydrogen technologies is still required, and current energy-use systems in heavy industry and heavy transport will need to be technically adapted before they can use hydrogen as a fuel.⁹⁵

In order for clean hydrogen to become competitive with conventional fuels for transport and fossil-based feedstock (with the inclusion of the cost of carbon), some technology routes need further improvements in particular in sectors that are difficult to decarbonise by other means, such as heavy duty transport (trucks, coaches, trains and ships) – especially in the areas of investment cost reduction and efficiency increases⁹⁶.

2.1.2. The Clean hydrogen value-chain not ready for large scale production, distribution and use of hydrogen

Currently, few complete value chains for hydrogen, from production to end-use, are operational across the EU.^{97,98} Several hydrogen applications still need to be technologically improved and tested before they can be successfully implemented into larger scale systems.^{99,100} This will be the core focus of the proposed partnership. While recent demonstration projects have affirmed the success and potential value of individual hydrogen technologies, knowledge transfer between project teams and across industries remains limited.^{101,102} As stated by the IEA,¹⁰³ “for novel applications (especially those at low TRLs)

and complex demonstrations, there might still be a case for public R&D support. Demonstration projects must be linked to overall energy policies and strategies, to avoid one-off projects that do not contribute to sustainable scale-up”.

Regarding the distribution of hydrogen, there are still many different R&I issues to address which is leading to a slow development of infrastructure and holding back widespread adoption.¹⁰⁴ Infrastructural construction requires planning and coordination that brings together national and local governments, industry and investors. Transport, storage and distribution are at risk of becoming a bottleneck for the accelerated rollout of hydrogen technologies at scale. This central pillar between production and consumption will require new (pipelines, refuelling stations) and old (existing gas infrastructure, salt caverns) solutions to work together in a decarbonised energy system.¹⁰⁵

In addition to its relatively high costs, its “difficult-to-prove” quality, reliability and efficiency, several other factors have inhibited hydrogen’s integration into existing large-scale systems and markets. Important players in industry and in the public sector have not yet developed strong, coordinated policies or set strategic visions regarding the future role of hydrogen.^{106,107} Even though there is today a consensus around the fact that clean hydrogen is the best and sometimes only alternative to decarbonise hard to abate sectors, larger-scale markets for hydrogen production and use have not yet been created.¹⁰⁸ Competing technologies are gaining a share in markets where hydrogen could play a role, but where higher costs are preventing its uptake.^{109,110,111} For example, renewable power plant operators increasingly rely on batteries to store excess electricity, rather than on electrolyzers and hydrogen storage options.¹¹² As hydrogen applications do not currently play larger roles in the power, industry and transport sectors, the hydrogen supply chain remains disjointed and underdeveloped.^{113,114,115}

Market-enabling regulatory frameworks to govern the production and use of key clean hydrogen applications are currently not adequate.^{116,117,118 119} However, as clean hydrogen has gained traction as a potential decarbonisation solution, policy makers at the European level and in some Member States have started to consider designing and implementing coordinated strategic guidelines and regulations for hydrogen.¹²⁰

2.1.3. The clean hydrogen value-chain not optimized to address environmental, health and safety issues and take up of these technologies in the EU economy and society

The 382 respondents to the Open Public Consultation on the Clean Hydrogen initiative, expressing their views on the needs of the future European Partnerships under Horizon Europe, indicated that this initiative would make a significant contribution to the EU efforts to achieve climate-related goals.

Difficult-to-decarbonise sectors including maritime transport, aviation, heavy-duty trucking, rail, and energy-intensive industry remain high emitters. Without the decarbonisation of these key sectors, it will be almost impossible for EU Member States to meet their climate targets.¹²¹ It is widely recognised that clean hydrogen can significantly contribute to this effort.^{122,123}

Nevertheless, recent research initiatives focused on the public perception of hydrogen show that public awareness of hydrogen technologies is still relatively limited.^{124,125} There are also

lingering concerns among the public regarding hydrogen safety.^{126,127} At the same time, very few public initiatives have focused on educating the public with respect to hydrogen.^{128,129}

Additionally, the EU and Member States have the potential to stimulate investments in clean hydrogen by adopting adequate measures that would drive widespread emission reductions in difficult-to-decarbonise sectors.^{130,131} Such measures could create market conditions for hydrogen applications in sectors where it is currently difficult for hydrogen to gain access.¹³²

2.2. What are the problem drivers?

2.2.1. *Clean hydrogen applications more expensive than competing technologies, and not yet fully reliable nor of sufficient quality for take up*

Since research on many technologies is still relatively novel, mechanisms for producing and using hydrogen are still expensive and relatively unrefined. Technologies for hydrogen production, distribution and end-use should still be technically and systematically improved.¹³³

Scientific advancement will be required to secure cost reductions and efficiency improvements in the production and use of applications at higher TRLs. Cost reduction and efficiency gains will ensure that hydrogen technologies can compete and gain market share in end-use sectors that cheaper low-carbon technologies currently dominate.^{134,135}

Consistent scientific development at lower TRLs will also be necessary to ensure that Europe's hydrogen technologies achieve the highest possible technical quality so they can compete with their international equivalents as hydrogen markets develop worldwide.^{136,137}

2.2.2. *Fragmented development of key interlinked clean hydrogen applications associated to limited cross-sectoral collaboration*

The FCH JU and FCH 2 JU primarily supported the development of key hydrogen applications to higher TRLs¹³⁸ though only a few pilot projects so far have included multi-sector actors from multiple links in the hydrogen value chain.¹³⁹

Research on different hydrogen applications is starting to become integrated, but overall the development of key applications remains fragmented, with restricted co-creation of new products and services and a limited capitalisation from high TRL ready to lower TRL ready applications along all value chains. Lack of coordination leads to inefficiencies that can increase the costs of hydrogen technologies. Fragmented technological development adds complexity to hydrogen's entry into mass markets.¹⁴⁰

2.2.3. *Limited large-scale deployment of clean hydrogen generation capacity*

Many industrial and research stakeholders interviewed for the impact assessment consider that the FCH 2 JU has not supported enough large-scale demonstration projects on clean hydrogen production, especially in large-scale coupling with renewable power plants to generate necessary investments in mass manufacturing capacity for production equipment.¹⁴¹ Large-scale demonstration projects are vital in proving the feasibility of and potential for using large-scale electrolyzers.¹⁴² They instil in investors the confidence necessary to back wider market deployment of these technologies. This issue will be partly addressed in the Horizon 2020 Green Deal Call, under preparation.

2.2.4. *Underdeveloped and non-adapted infrastructure for storing, transporting and distributing hydrogen*

Transportation, distribution, and refuelling infrastructure will be necessary to enable the uptake of hydrogen in the power, transport, and industry sectors.¹⁴³ Cross-border infrastructural networks spanning significant distances between Member States will need to

be constructed to connect optimal clean hydrogen production regions to optimal hydrogen consumption regions.^{144,145} Development of the required infrastructure will require R&I activities, for example to address the challenges of injection of hydrogen into the gas grid, demonstration of large volume refuelling stations (> 1 tonne of hydrogen per day) and to address issues related to transportation of liquid hydrogen by trucks.

Infrastructure development goes beyond the scope of the proposed partnership and will be supported by other funding programmes such as the Connecting Europe Facility (CEF). However, this requires intense coordination between industrial players and policy makers in different Member States. Infrastructure development has stalled partly in response to a perceived lack of demand for hydrogen. However, hydrogen applications cannot enter mass markets or deploy at large scale until this infrastructure is in place.

The construction of an integrated infrastructural network will also bring together important players from different segments of the hydrogen value chain and will form the backbone of a more cohesive, complete hydrogen ecosystem.¹⁴⁶

2.2.5. Lack of large-scale deployment of clean hydrogen end-use applications

There have not been enough large-scale demonstration projects on key technologies to generate the necessary investments in mass manufacturing capacity for end-use products and equipment.¹⁴⁷ Large-scale demonstration projects are vital in proving the feasibility of and potential for using large-scale fuel cell applications (Combined Heat and Power (CHP) systems, vehicles...), burners or turbines.¹⁴⁸

2.2.6. Insufficient demand, acceptance and preparation for clean hydrogen solutions

Public awareness and public knowledge on hydrogen are still limited. Existing and previous partnerships on clean hydrogen have prioritised technological development, with less research devoted to engaging and educating the public. Very few initiatives have sought to educate the public on the role hydrogen might play in large-scale decarbonisation.^{149,150}

Local and regional community organisations and authorities – which can play instrumental roles advocating for clean hydrogen integration into their regional economies – often lack the up-to-date information needed to design policy proposals and to allocate funding

efficiently.¹⁵¹ There is also evidence to suggest that the public remains concerned regarding the safety of hydrogen technologies.^{152,153,154}

Additionally, further educational efforts will be required to train the engineers, executives, and policy-makers necessary to support the integration of hydrogen into existing systems and markets and to develop the capacity required to enable a cross-sectoral hydrogen transition.¹⁵⁵

Beyond education and communication, one of the roles of the proposed initiative will be on co-creating solutions, starting from the users' needs (user which can be citizen but also public authorities), along with testing and experimentation. Research on social sciences and humanities will be key to understand and analyse how to get citizens' engagement on these relatively disruptive hydrogen solutions.

2.2.7. Inadequate regulatory, policy and financing frameworks for clean hydrogen

This issue is out of the direct scope of the proposed initiative but it is important that these aspects should be considered early enough to be able to engage with standardisation and regulatory bodies, anticipating what would be needed for increased demand, acceptance, and ultimately uptake of hydrogen solutions. In this context, Pre-Normative Research (PNR) will be an important aspect of the proposed initiative.

Policy makers would need to develop a regulatory framework to govern the production and use of clean hydrogen applications. EU regulation concerning renewable energy, alternative fuel infrastructure, gas infrastructure, market design, CO₂ emission standards and clean vehicles would need to be adapted in order for clean hydrogen to be recognised for its climate contribution.¹⁵⁶ A clear definition of clean hydrogen should be the first step to ensure the proper integration into all regulatory frameworks. The lack of coordinated regulatory frameworks complicates hydrogen's entry into mass markets. Needless to say, harmonised regulatory frameworks would encourage investors and enable more hydrogen applications to be deployed at larger scales.

2.3. How will the problem(s) evolve?

Without any action, it is anticipated that:

¹⁵¹ Fuel Cells and Hydrogen Joint Undertaking 10th Stakeholder Forum (2017), Fuel Cell and Hydrogen Technology: Europe's Journey to a Greener World, available at <https://op.europa.eu/en/publication-detail/-/publication/15d2c3b7-c502-11e7-9b01-01aa75ed71a1>

¹⁵⁴ Hydrogen Europe (2017), Hydrogen safety – available at <https://hydrogeneurope.eu/hydrogen-safety>

¹⁵⁵ Fuel Cells and Hydrogen Joint Undertaking (2011), Project Hyprofessionals – Development of Educational Programmes and Training Initiatives Related to Hydrogen Technologies and Fuel Cells in Europe – available at <https://www.fch.europa.eu/project/development-educational-programmes-and-training-initiatives-related-hydrogen-technologies-an>

¹⁵⁶ Hydrogen Europe (2018), EU Legislative framework for implementation of Hydrogen in different applications – available at https://www.waterstofnet.eu/asset/public/powerogas/Conference/10-Nicolas-Brahy_Hydrogen-Europe-HyLaw-Regulation-Overview.pdf

- Hydrogen applications will not be able to be deployed at scale, nor will they be able to achieve cost reductions;
- Improving the environmental performance of energy intensive industries will be more complex, lengthy, expensive and will hinder reaching the 2050 targets; and
- Several European industrial sectors will be at greater risk of losing competitiveness in the global market.

The core problems in the field of clean hydrogen will persist and worsen over time, if action is not taken to address them.¹⁵⁷

The costs of clean hydrogen solutions will not decrease on their own. Without action hydrogen technologies will not be in a position to compete with competitor low-carbon technologies like BEVs and battery storage, since those will likely achieve further cost reductions and efficiency gains as they have already achieved economies of scale.¹⁵⁸ As a consequence, Europe's competitive positioning in the hydrogen industry will deteriorate.¹⁵⁹

It will become increasingly difficult for hydrogen solutions to enter mass markets and deploy at large scales, if policy makers and industrial players begin to regard hydrogen as a less viable solution. Unless efforts are made to promote technological advancements across sectors and develop cohesive, complete value chains for hydrogen production, distribution, and use, heavy industry and heavy transport sectors will not be able to integrate clean hydrogen solutions into their operations.¹⁶⁰ Sector coupling will then likely be regarded as infeasible. Difficult-to-decarbonise sectors will remain highly emissive and Member States will not be able to achieve their climate targets.¹⁶¹

Mass manufacturing capacities will not be developed, and the hydrogen value chains will not effectively industrialise, preventing efficiency gains and potential cost reductions.¹⁶²

If the public is not sufficiently educated regarding hydrogen solutions, these are unlikely to garner the support they need for wider-scale deployment. Additionally, it will be more difficult to overcome concerns regarding hydrogen safety if proper educational mechanisms are not put into place. Finally, the workforce required to enable a cross-sector, cross-border hydrogen transition will be underequipped if further educational efforts are not made to build capacity.¹⁶³

3. WHY SHOULD THE EU ACT?

3.1. Subsidiarity: Necessity of EU action

In the context of the specific complex and interlinked value chains of clean hydrogen where costs, risks and an important number of players for new developments depend on effective cooperation, **inter-sectoral collaboration at the European level** is essential to succeed in demonstration and deployment at scale. The exchange and pooling of knowledge between the stakeholders is critical to avoid duplication, extract lessons and especially successes in order to improve fundamental and applied research. Standards and norms should be addressed at international level, where the EU should ensure having only one voice.

The European hydrogen industry and research stakeholders, when acting alone or through small size consortia, do not have all the required knowledge from fundamental scientific to market oriented, are not integrating all concerned sectors and are not able to manage all the risks. In addition, they do not have sufficient size for the type of risk-sharing projects involved for expensive demonstration of innovative solutions. The nature and the size of the challenges also go beyond the capacity of individual Member States.

Due to the increasing number of applications, derived from existing emerging uses and targeted in the proposed initiative, collaboration and coordination between industrial and research base actors active in the hydrogen economy is essential. It is a prerequisite to retain the competitive position of the concerned industrial sectors.

3.2. Subsidiarity: Added value of EU action

There are several national R&I schemes, such as in Germany, France, Denmark and Italy which are, committing significant budgets on hydrogen - in total approximately EUR 1 billion funding over a seven-year period.¹⁶⁴ However, these are insufficiently coordinated within the Member States, between Member States and with the EU, thus leading to a possible duplication of activities¹⁶⁵ and lack of efficiency.

With a clear climate policy and clear objectives for 2030 and for 2050, there is a strong need for directionality of European investments as well as additionality. EU action would complement the national schemes (reflected in NECPs) to provide a clearer policy approach, especially as innovations are urgently needed to realise the climate action plan and its

Overall the results of the Member States consultation on the Inception Impact Assessment confirm the relevance of the proposed initiative on Clean Hydrogen, with 82% considering it very or somewhat relevant for their research organisations, including universities, 79% for their national policies and priorities, and 72% respondents found the proposed partnership as relevant for their industry. In terms of overcoming fragmentation within Europe, the challenges of delivering improved coordination between Member States' clean hydrogen research and innovation support remain significant, therefore increasing the importance of an EU action.

objectives.

¹⁶⁵ Competitiveness of the EU Aerospace Industry with focus on Aeronautics Industry, Ecorys, 2009

1. European Partnerships under Horizon Europe: results of the structured consultation of Member States

4. OBJECTIVES: WHAT IS TO BE ACHIEVED?

4.1. General objectives of the initiative

Based on the identified problems, the overall objective of the proposed Clean Hydrogen initiative is to produce noticeable, quantifiable contributions towards the achievement of climate targets in 2030 and pave the way for climate neutrality by 2050. Reaching this long term vision means capacity to supply hydrogen at scale and simultaneously boosting demand. Therefore, the scope of hydrogen applications has to increase from its present focus in FCH 2 JU on transport applications (passenger cars and buses), fuel cells and electrolysers, by addressing R&I issues related to production, distribution and storage of clean hydrogen to supply hard to decarbonise sectors such as heavy industries (steel, cement, chemical, ...) and heavy duty transport applications (trucks, buses, rail, ships, ...). With the emergence of these new applications, the supply chain has become more complex and continuous improvements¹⁶⁶ (new materials¹⁶⁷, efficiency, reliability, lifetime¹⁶⁸, cost¹⁶⁹) are needed for all applications.¹⁷⁰

The following general objectives have been identified:

- Strengthen and integrate EU scientific capacity to support the creation, exploitation and sharing of knowledge to accelerate the development and improvement of advanced clean hydrogen applications ready for market, across energy, transport, building and industrial end-uses.
- Enable large scale deployment capacity for key parts of the clean hydrogen value chain and strengthen the competitiveness of the EU clean hydrogen value chain (notably SMEs) making the most of all future opportunities, accelerating the market entry of innovative competitive clean solutions to support the decarbonisation of the EU economy.¹⁷¹
- Ensure a safe and frictionless deployment of clean hydrogen technologies for the greening of hydrogen generation and use through innovative solutions.

These objectives address the clean hydrogen economy from a broad perspective and are aligned with the objectives of the Horizon Europe framework. If pursued, they will contribute to the pursuit of several Sustainable Development Goals including: SDG7 (Affordable and clean energy); SDG11 (Sustainable Cities and communities); and SDG13 (Climate action) and to a lesser extend SDG8 (Decent work and economic growth) and SDG9 (Industry, innovation and infrastructure).¹⁷²

¹⁶⁶ The Appendix: Analytical report on the Strategic Value Chain (SVC) on Hydrogen technologies and systems in the frame of the Strategic Forum on IPCEI (called the “IPCEI Appendix”), points out the special techno-economic challenges of reducing the cost, increasing the efficiency and reducing the use of Critical Raw Materials (from FCH JU lists) (p 29)

¹⁶⁷ The “IPCEI Appendix” addresses, as example, the development and qualification of new materials to continue improving high pressure hydrogen storage (p 10)

¹⁶⁸ Example of buses lifetime addressed in the “Competitiveness Analysis” (p 67)

¹⁶⁹ The “IPCEI Appendix” points out the cost of producing hydrogen should be reduced (p 13), FCEV should cost similar to electrical vehicles (p14), technologies cost reduction is also a question of competitiveness with other regions especially Asian competitors (p28). The “Competitiveness Analysis” illustrates cost decrease expectations by 2030, for many different applications, depending on mass production (p 48)

¹⁷⁰ See Annex 6 for general information on the hydrogen sector.

¹⁷¹ Please see Chapter 1 f or an in-depth discussion on EU competitive positioning across member states and different hydrogen applications.

¹⁷² European Commission International Cooperation and Development (2019), The Sustainable Development Goals – available at https://ec.europa.eu/europeaid/policies/sustainable-development-goals_en

4.2. Specific objectives of the initiative

In order to achieve the general objectives, seven specific objectives are defined. These specific objectives respond to each of the problem drivers discussed in Section 2.2. The list of specific objectives is the following:

- Improve through research and innovation the cost-effectiveness, reliability and quality of clean hydrogen applications developed in the EU. The objective is to deliver hydrogen based solutions at a price equivalent to the alternatives by 2030;
- Reinforce the EU scientific and industrial ecosystem for innovative clean hydrogen applications;
- Demonstrate and scale-up clean hydrogen applications to stimulate large-scale generation capacity. The objective is to produce clean hydrogen at a cost of ~EUR 1.5-3/kg by 2030, allowing penetration into mass markets ¹⁷³;
- Accelerate through demonstration the co-deployment of EU storage, transport and distribution infrastructures for innovative clean hydrogen solutions. The objective is to reduce the distribution costs to less than EUR 1/kg of hydrogen at scale by 2030 ¹⁷⁴;
- Prove the economic and industrial capacity of clean hydrogen to provide long-term climate neutral innovative solutions across the power and gas, maritime, aviation, rail, heavy duty transportation, building and industrial sectors;
- Increase public and private awareness, acceptance, demand and uptake of clean hydrogen solutions.

Note that issues relating to the policy, regulatory and financial framework have to be addressed in parallel and/or factored in so that the initiative is enabled to achieve its objectives and effectively contribute to the climate policies and targets from a broader perspective.

Intervention logic of the initiative

Many of the respondents to the Open Public Consultation took the opportunity to underline key messages regarding the initiative:

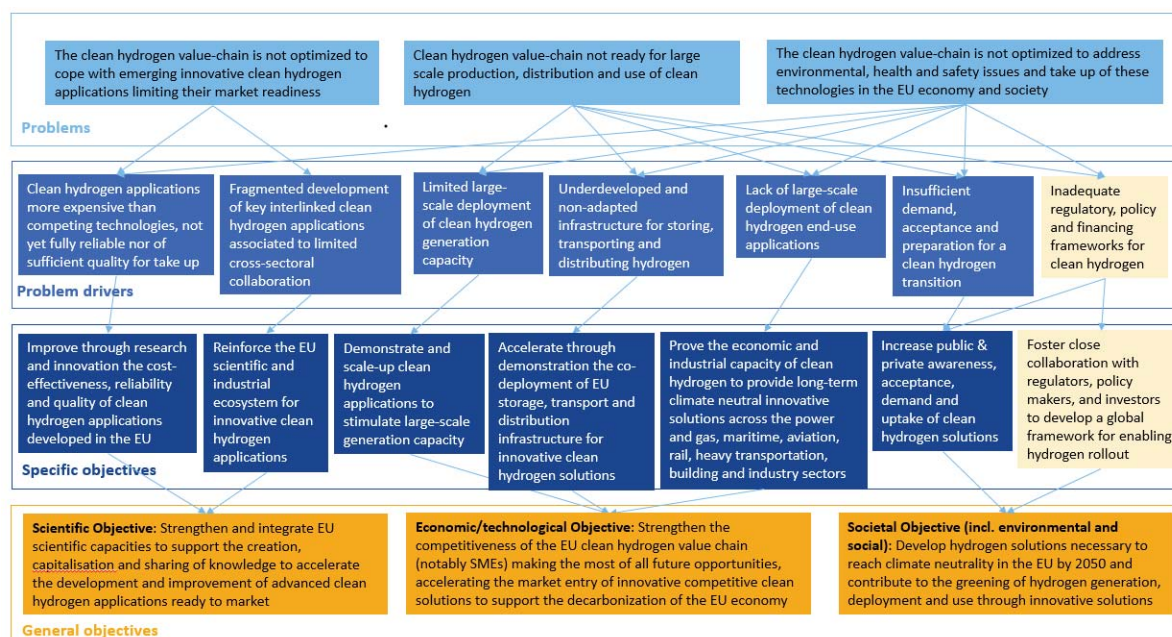

- The global positioning of Europe: outlining the role of global competition (including the role of technology), the importance of autonomy for Europe and the ability of Europe to act as a key player at the global level.
- The need for a balance between policy objectives and private sector interests.
- The importance of the transition between research and innovation (implementing research results in the market).
- The importance of multidisciplinary and specifically cross-sectoral/cross-partnership collaboration.

The relationship between the general and specific objectives of the potential initiative on Clean Hydrogen is shown in Figure 9.

¹⁷³ Production costs of clean hydrogen are linked to Electrolyser costs. Those have already been reduced by 60% in the last ten years, and are expected to halve in 2030 compared to today with economies of scale. In areas with low-cost renewable electricity, electrolyzers are expected to be able to compete with fossil-fuel hydrogen in 2030.

¹⁷⁴ Distribution costs can vary dramatically between transport means (e.g. pipeline (15 cents/kg) versus trucks versus liquid carriers, etc....) and context of usage. The figure of “less than 1 euro” is for the specific case of transport by truck for mobility application.

Figure 9: Intervention Logic for the initiative on Clean Hydrogen

How would success look like?

Should the initiative deliver on its specific objectives, it is expected that it would translate in practice into the following impacts:

Scientific impacts

- Hydrogen applications are more competitive, efficient and reliable. A key milestone would be the achievement of the time-bound targets of producing clean hydrogen at a cost of ~EUR 1.5-3/kg and to reduce the distribution costs to less than EUR 1/kg of hydrogen at scale by 2030. The EU maintains its leading position for cutting edge research and innovation in hydrogen applications

If the initiative can push for continued technical improvement of hydrogen applications and encourage distinct industries to collaborate on research projects, new potential science- and technology-based applications for hydrogen are likely to emerge. Additionally, the EU will be able to maintain the role it currently plays as a global hub for hydrogen research and innovation for the primary benefit of EU leading research institutions and innovative SMEs.

Economic/technological impacts and impact on SMEs

- EU validates its ability to deploy economically viable hydrogen generation at scale
- EU validates its ability to deploy hydrogen infrastructures at scale
- EU validates its ability to scale-up clean economically viable hydrogen end-use applications in heavy-duty transport and energy-intensive industries – maintaining global competitiveness
- EU growth in the hydrogen economy, especially for SMEs

Successful realisation of the objectives would result in a strengthened EU hydrogen industry. The EU would be able to pursue its climate targets while protecting the competitiveness of its energy intensive industries and heavy transport sectors. SMEs which have developed innovative hydrogen technologies would be likely to thrive and receive increased investment. There is also potential for localised economic growth in areas where hydrogen hubs or valleys are developed. This would impact stakeholders across the EU;

Member States which can capitalise on hydrogen development and uptake could incorporate a new, competitive industry into their economies. Across industrial and transport sectors, companies will be equipped to comply with climate standards without sacrificing competitiveness. There are substantial opportunities for SMEs to grow successful businesses and position themselves strongly within the hydrogen supply chain.

Societal impacts

- The EU's maritime, aviation, rail and heavy-duty transport sectors, as well as its gas grid, can progressively decarbonize so the EU can meet its climate targets
- Reduction of carbon emissions and pollution to air, water and soil
- Knowledge capacity built up to support the hydrogen transition while increasing public support for additional hydrogen policy and regulatory frameworks increases

Environmental impacts

If executed in full, the initiative could lead to a substantial environmental impact. Especially in sectors that are difficult to decarbonise, increased support for and investment in hydrogen applications would enable energy-intensive industries and heavy-duty transport to fully decarbonise. In turn, this would strengthen the EU low carbon society and enable the EU to meet its climate targets. This would impact a wide range of stakeholders in the long-term, from company owners to citizens and local, Member State, and EU-level policy makers. In addition to decarbonisation goals, a clean hydrogen economy can significantly contribute to decrease outdoor pollution, thanks to the replacement of fossil-based fuels and feedstock.

Social impacts

Additional demonstration projects are likely to generate further public interest in hydrogen. At the same time, increased public outreach and education on hydrogen would likely create a basis of public support for hydrogen applications. Getting citizens' engagement and co-creating solutions, starting from the users' needs would facilitate the integration of innovative solutions into societies, from local to national to international levels. Proof of hydrogen solutions' feasibility would also likely prompt policy makers to act quickly and develop regulatory frameworks that can effectively govern applications' uses.

Increased public outreach on hydrogen would in turn increase public support for hydrogen; in a best case scenario, policy makers would receive public mandates/public pushes for developing policies that enable hydrogen's integration into existing systems, similar to how public support for renewables integration bolstered EU policymakers' support for renewable power in recent years. Finally, the deployment of hydrogen produced from renewable electricity would significantly facilitate and enable the deployment of renewable electricity production at scale.

Based on the interviews and as shown from the result of the Open Public Consultation, the results and impacts of the initiative can best be achieved if industry and research are involved at all stages, starting from basic research up to ready-to-market level, in order to develop and bring hydrogen technologies to large deployment scales. This would ensure that research and development are in line with the overarching goals, and also avoid fragmentation and duplication of efforts.

4.3. What is needed to achieve the objectives – Key functionalities needed

Given the focus of the impact assessment on comparing different forms of implementation, the identification of “**key functionalities needed**” allows making the transition between the

definition of the objectives and what would be crucial to achieve them *in terms of implementation*. These functionalities relate to the type and composition of actors that have to be involved, the type and range of activities that should be performed, the degree of directionality needed and the linkages needed with the external environment.

4.3.1. *Type and composition of actors to be involved*

To be able to achieve the scientific objectives of the proposed clean hydrogen initiative, all sectors concerned by the hydrogen economy should be given the possibility to get involved in preparing and implementing the Research and Innovation Agenda, in particular priority should be given to solutions and actors that can contribute most to the energy and climate objectives of the EU. The concerned sectors (involving industry and SMEs), in addition to the hydrogen manufacturing actors, should comprise of at least heavy industry using hydrogen as feedstock, the biomass/biogas sector, the power sector, where hydrogen can act as long-term storage for renewables generation, the gas and grid operators, the transport sector, the building and heating sector and project developers who can coordinate efforts in project implementation, especially to facilitate sector coupling. In addition, the public sector should also be involved, especially regional and national authorities, the latter being responsible to set up climate policies (ideally by integrating hydrogen into the NECP 2030) and measures (market mechanisms) to fill in the huge gap between ready-to-market technology development and large-scale uptake. National authorities should also address cross-border issues like infrastructure and corridors (pipelines, hydrogen refuelling stations ...), norms and standards.

Despite the potential of hydrogen to contribute to the decarbonisation of many different sectors, one has to acknowledge that the deployment of hydrogen and fuel cells is only marginal today (see Annex 6). As a consequence, there is no evidence of anti-competitive behaviour from the side of partners or in product markets. To accelerate the commercial readiness of hydrogen technologies, the proposed Clean Hydrogen Partnership is building on the work of FCH 2 JU which made the start of commercialisation of a first series of applications possible. It will aim at bringing a second series of applications to commercial level in particular in industry heat and feedstock, power generation and hard to abate transport sectors.

This increased collaboration between researchers, SMEs and industrial players will also be critical to achieve the economic/technological objectives by facilitating the entry of hydrogen into multiple markets. It will also enable the development of a more cohesive, complete hydrogen ecosystem with strongly linked value chains from clean production to efficient end-use.¹⁷⁵

Finally, the initiative would benefit from involving non-EU market players with their own strengths that can complement EU R&I actors and from the coordination of well-established partnerships with international actors e.g., the International Partnership for Hydrogen and Fuel Cells in the Economy (IPHE); Mission Innovation – Renewable and Clean Hydrogen Challenge, Clean Energy Ministerial (CEM) Hydrogen Initiative, Hydrogen Energy Ministerial (HEM), and so on.

All categories of respondents to the Open Public Consultation clearly see stakeholders from industry as the most relevant in setting a joint long-term agenda, followed by academia and governments (Member States and Associated Countries).

4.3.2. *Type and range of activities needed*

For hydrogen, we are talking today about a very dynamic sector and community. Responsiveness to new technological developments will be a must, meaning that it should be ensured that the partnership will be able to react quickly and efficiently in particular considering the proposed substance of cooperation with the partnership seeking now to address broader **research and innovation aspects related to production, distribution, infrastructure and storage of hydrogen**. As such, it is open to newcomers as mentioned in paragraph 4.3.1.

A number of activities have been identified to ensure flexibility of implementation and create the expected impacts such as:

- (i) Seek synergies with R&I programmes of other sectors and initiatives - strong links are already identified with the candidate European Partnerships on: towards zero emission road transport transforming EU's railway system, clean aviation, clean steel, zero emission waterborne transport and processes 4 planet;
- (ii) Coordinating R&I actions ranging from concept to demonstration and validation activities (covering all Technology Readiness Levels), ensuring inclusion of new actors and integration of extended value chains;
- (iii) Developing deployment and piloting activities to ensure flexibility over time across the range of applications implemented;
- (iv) Communication and dissemination activities to ensure societal and political support for envisaged developments and overseeing actions fostering regulation or standardisation
- (v) Co-creating solutions with end-users, emphasising the importance of flexibility in addressing different target groups over time, including industrial end users for which low carbon alternatives are not evident.

4.3.3. *Priority setting system and level of directionality required*

A common vision for the initiative addressing an integrated research and innovation agenda cannot be achieved in the absence of a strong commitment of industry, the research organisations and the public sector in Europe.¹⁷⁶ It is critical that stakeholders with long-term commitments in the hydrogen sector remain involved in the initiative. Industry should be ready to continuously improve technologies and applications, once uptake is starting, in order to constantly improve efficiency, cost, reliability and performance. Clean hydrogen R&I activities (under Horizon Europe) should be based on cooperation between consortia of

In the Open Public Consultation, the following activities were considered the most relevant: deployment and piloting activities, joint R&D programme, collaborative R&D projects, whereas input to regulatory aspects and co-creation of solutions with end-users scored less.

stakeholders, working together on the basis of consented multi-annual (and possibly multi-projects) actions targeted at specific technological goals.

Less mature applications still need to be improved and will need to involve research and industry players in the long-term. Political commitment from both Member States' and the

¹⁷⁶ The Strategic Research and Innovation Agenda, Hydrogen Europe, December 2019, p 7

EC is of utmost importance – as hydrogen technologies are not yet economically competitive. Strong signalling and support from governments is necessary to ensure that hydrogen applications will play a long-term role in future energy/industry/transport landscapes. To conclude, the level of directionality should be as high as possible for the initiative to reach its objectives. The strategic vision should be shared and implemented as much as possible by the key stakeholders along the whole value chain.

4.3.4. *Coherence needed with the external environment*

Due to its versatility and cross-sectoral integration, clean hydrogen should be addressed through close collaboration frameworks with other programmes and initiatives to create synergies and limit duplications. Regarding other initiatives, it is crucial to share views on the ways to integrate hydrogen into the concerned sectors (e.g. trucks, coaches, rail, maritime, gas and power, grids, aviation, building, ...) and ideally to share a common vision to define where to concentrate efforts. Complementary calls, including their funding and management, would be the next step to ensure full coherence with other initiative's agendas.

Other key elements related to the framework conditions will play a role in the ability of the initiative to reach its objectives. This concerns in particular the next steps after R&I activities, namely scaling up, market deployment, regulatory frameworks, infrastructure deployment, customer acceptance, etc. For supportive framework conditions, the initiative should ensure close collaboration and engagement with end users, citizen, policy makers and regulators. Furthermore there is a need to link with other crucial funding and financing mechanisms, in particular articulation with the Connecting Europe Facility; ETS Innovation fund; IPCEI and risk capital players to finance scaling up and deployment activities and financing institutions to bring solutions to the market will be considered.

5. WHAT ARE THE AVAILABLE POLICY OPTIONS?

This section describes the specific functionalities that could be provided under the baseline scenario of traditional calls and the different options of different types of European partnerships.

5.1. What is the baseline from which options are assessed?

The baseline scenario used in this impact assessment is a situation without a Partnership and only traditional calls of Horizon Europe. Given that there is a predecessor Partnership as well as other funding sources in the area, these will continue generating effects even if there is no new Partnership. In particular it is expected that these already existing initiatives will still have an impact in the coming years.. This is taken into account in the effectiveness assessment.

In parallel, the baseline situation means that the current implementation structure of the Article 187 would be closed, which bears winding down and social discontinuation costs. There would also be financial cost-savings related to the closing of the structure, related to operations, staff and coordination costs in particular. This is taken into account in the efficiency assessment.

Table 1: Key characteristics of the baseline situation - Horizon Europe calls

What is feasible under this option - Functionalities of option
--

Enabling appropriate profile of participation	<ul style="list-style-type: none"> - The Commission would need to prepare the Strategic Research and Innovation Agenda (SRIA) by consulting a wide range of actors, i.e. hydrogen equipment manufacturers, end-use sectors (energy intensive and hydrogen feedstock industry, heavy transportation, building) and their equipment manufacturing industry, gas operators and industries, the gas and power sectors (including renewable), related research organisations and academia and representatives of local and regional authorities or communities (as key player to build ecosystems). This could be challenging, considering the current evolution of the hydrogen economy and the early stage of building up a clean hydrogen EU strategy (not existing at the moment). - The implementation of the SRIA would need further consultation with research and industrial organisations to deal with technical, economical and industrial knowledge as expertise is needed to address hydrogen versatility in an evolving landscape. - The specification of calls over the period of the Framework Programme will reflect the need for an evolving profile of participation, with different consortia forming at different stages to take different types of activity forward.
Supporting implementation of R&I agenda	<ul style="list-style-type: none"> - Implementation would rely on standard infrastructure underpinning the open calls procedure, drawing on resources of relevant executive agencies and Commission IT systems. - Administrative costs for the European Commission would be significantly reduced. - Calls for proposals would be published in the work programmes of Horizon Europe. - Transparency and open publication of results would ensure their availability to interested parties. - Dissemination of knowledge and share of practice would happen predominantly among partners within the calls consortia.
Ensuring alignment with R&I agenda	<ul style="list-style-type: none"> - Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from representatives of all relevant stakeholders. - Specification of calls for activity at higher TRLs, particularly demonstration projects, would need substantial input from industry. - R&I activity would focus on the short to medium term needs of industry and fundamental research, although it would also include long term applications and trends. - Commission input into specification and oversight of calls would ensure alignment with overarching policy objectives as well as integration with other programmes. - Selection of high TRL projects would require provision of external expert (and independent) advice to the Commission.
Securing effective leveraging of resources	<ul style="list-style-type: none"> - Progress of R&I effort would depend on EU funding, with leveraging of industry support coming mainly from their financial contributions determined by Horizon Europe rules. - Demonstration programmes would require significant in-kind support and collaboration from industry.
Key differences compared to the current situation	<p>The commission would need to complete the SRIA and recruit new resources i.e. Policy Officers to design, implement and monitor the research programme. There would be significantly weakened contacts with industry & research, since in the absence of a partnership Hydrogen Europe and Hydrogen Europe Research Organisations may well cease operation. Dissemination of results, promotion of safety and standards through the partnership would no longer occur.</p>

5.2. Description of the policy options

Table 2: Key characteristics of Option 1 – Co-Programmed European Partnership

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation	<ul style="list-style-type: none"> - The partnership would enable participation by all key stakeholders contributing to the specification and delivery of the SRIA. - It would need to consult with a wide range of stakeholders, within its membership to ensure that the SRIA, and ultimately the work programme, is aligned with industry, research and market needs. - At the same time, it would offer the flexibility to change the profile of participation over time, with new partners joining to support new areas of activity in response to emerging results and changing priorities.
Supporting implementation of R&I agenda	<ul style="list-style-type: none"> - Implementation would rely on standard administrative infrastructure underpinning the open calls procedure, drawing on resources of relevant executive agencies and Commission IT systems. - Calls for proposals would be published in the work programmes of Horizon Europe.

	<ul style="list-style-type: none"> - Transparency and open publication of results would ensure their availability to interested parties.
Ensuring alignment with R&I agenda	<ul style="list-style-type: none"> - Work programmes would need to reflect the requirement for R&I activity across TRLs, with input from the various partners to achieve an appropriate balance of activity directed towards different markets. - The partnership would be responsible for ensuring that priorities for calls were specified in line with R&I priorities, including demonstration projects. - R&I activity would be likely to focus on the medium-term needs of industry and research. - Programme Committee would ensure alignment with overarching policy objectives and coordination with related programmes.
Securing effective leveraging of resources	<ul style="list-style-type: none"> - Aspirations for partner contributions would be clearly defined at the outset. - Industry or research commitments would not be legally binding. - Expected in-kind contributions from the private sector would be identified in the work programme.

Table 3: Key characteristics of Option 2 – Institutionalised European Partnership (Article 187 TFEU)

	What is feasible under this option - Functionalities of option
Enabling appropriate profile of participation	<ul style="list-style-type: none"> - The partnership would enable participation by all key stakeholders contributing to the specification and delivery of the SRIA. - The implementation of the agenda would not need further consultation, as the structure, thanks to its technical, economical and industrial knowledge and acquired expertise, allows self-management. - It would provide a forum or even a platform for consulting stakeholders on R&I priorities and the work programme, ensuring that they are aligned with industry, research and market needs and with the agenda of other partnerships and sectoral programmes. - Participation would be less flexible than under other options, but it might nevertheless be possible to change the profile of participation over time, with new partners joining to support new areas of activity in response to emerging challenges and evolving priorities.
Supporting implementation of R&I agenda	<ul style="list-style-type: none"> - A dedicated administrative structure would be established to coordinate the specification of R&I activity, manage implementation and report on the results (with administrative expenditure limited to a percentage of the budget). - Calls for proposals would be published broadly by the administrative structure. - Transparency and open publication of results would ensure their availability to interested parties. - Dissemination of knowledge and share of practices would happen among the stakeholders of the community, with potential diffusion activities managed by the partnership structure.
Ensuring alignment with R&I agenda	<ul style="list-style-type: none"> - The partnership would be responsible for specifying a work programme fully in line with the R&I priorities identified by industry and research organisations to fulfil the European policy needs, combining activities across low and high TRLs and in different areas. - The work programme would reflect the medium- and long-term needs of industry, the research organisations and society in adopting clean hydrogen solutions. - Commission participation in the partnership governance arrangements and approval of the work programme would help to ensure alignment with overarching policy objectives and enable integration with other programmes and initiatives.
Securing effective leveraging of resources	<ul style="list-style-type: none"> - Legally binding funding requirements would be clearly defined at the outset, with private sector partners expected to provide between 50% and up to 75% of partnership resources through in-kind and/or financial commitments.

5.3. Options discarded at an early stage

The co-funded partnership and an institutional partnership created under Article 185 of the TFEU are not considered relevant for the impact assessment on the Clean Hydrogen initiative. In a co-funded partnership option, the partners do not include private sector companies or private research organisations and instead include only public authorities with

research funders (or governmental research organisations) and other public authorities at the core of the consortium. These types of partnerships rely on pooling and/or coordinating national programmes and policies with Union policies and investments, to help overcome fragmentation. This form of implementation only allows to address public partners at its core (comparable to the Article 185 initiatives), with Member States that are partners in this partnership becoming the ‘owners’ of the priority and taking sole responsibility for its funding. Industry and research RD&I can nevertheless be addressed by the activities of the partnerships, but it does not make formal commitments and financial contributions, or decide the R&I priorities. In the context of a Clean Hydrogen initiative, industry and research involvement is vital as there is a definite need for industry and research to plan, deliver and fund research and innovation.

6. HOW DO THE DIFFERENT POLICY OPTIONS COMPARE?

Based on the objectives pursued by the initiative and the key functionalities identified to be able to achieve them, each option for implementation is assessed in terms of effectiveness, efficiency and coherence compared to the baseline scenario of traditional calls. The analysis is primarily based on the degree to which the different options would cater for the key needed functionalities. All options are compared to the baseline situation of traditional calls, which is thus consistently scored at 0 to serve as reference point.

6.1. Effectiveness

To be in line with the Horizon Europe impact framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. This section considers to which extent the different policy options would allow delivering these expected impacts – confronting what is needed (functionalities) with what each form of implementation can provide in practice. The assessments in this section set the basis for the comprehensive comparative assessment of all retained options against all dimensions in Section 6.4, based on a scoring system¹⁷⁷.

Scientific impacts

Concerning the efficiency and reliability of hydrogen applications and equipment, without a long-term focus and commitment from both the research and the industry communities, Europe’s hydrogen sector will not be able to adapt quickly enough to changing competitive forces, to the delivery of new low carbon solutions and the emergence of low carbon challenges.

The baseline option is unlikely to contribute to the emergence of new applications for clean hydrogen as it will struggle to reach new sectors and to prepare and implement a long-term agenda.¹⁷⁸ This option could easily manage fundamental R&I activities (and could be complementary to any type of partnership) if there was a clear centralised agenda pinpointing the climate and industrial priorities. Activities which need more coordination (including the demonstration of complex projects, technology comparison, increasing public awareness, and developing new business models) would need closer collaboration between research, industry and decision-makers to define cohesive work plans. This option does not

¹⁷⁷ A more in depth and detailed analysis of each policy option is provided in Technopolis Group (2020)

¹⁷⁸ Boston Consulting Group (2019), The Real Promise of Hydrogen – available at <https://www.bcg.com/publications/2019/real-promise-of-hydrogen.aspx>

provide such a framework or ecosystem of actors. However, this option could deliver improvements for low and medium TRL applications if a clear agenda is set up.

Option 1 could deliver more impact than the baseline option when it comes to higher TRL applications where a strong community with all actors is needed in order for all potential partners to liaise on complex projects. Its score would therefore be good compared to the baseline with +.

Option 2, by most fully involving research and industry with a long-term commitment, could contribute to the emergence of new applications and to continuous efficiency, quality and reliability improvements in applications and equipment. Its score would therefore be high compared to the baseline with ++.

With regard to the second scientific impact e.g. EU maintains its leading position for cutting edge research and innovation in hydrogen applications, **the baseline option** may allow some European organisations to maintain market-leading positions and cutting-edge research initiatives. However, without the deep involvement of industry in developing a roadmap and providing directionality, or without openness to a wide range of stakeholders, and given that the clean hydrogen economy and market are evolving constantly, it would be difficult to properly seize emerging market opportunities.

Compared to the baseline, **Option 1** could also help European organisations to maintain their leading positions because some industry involvement would be maintained and is therefore given a score of +.¹⁷⁹

However, **Option 2** through strong involvement of the research and the industrial community, would be more efficient than Option 1 and provide greater possibilities to adapt to the evolving hydrogen economy and to anticipate and seize emerging opportunities. It would also support increased knowledge diffusion between industrial players, public sector authorities and members of the public thanks to its broad community and internal expertise.¹⁸⁰ Its score would therefore be higher with ++.

Stakeholder opinion (from interviews)

A long-term shared vision, financial and structural commitment and the existence of a strong community are the 3 key pillars to tackle the evolving challenges of the clean hydrogen economy, not only from an RD&I perspective, but also more broadly to address regulatory, policy and awareness issues. The existing FCH 2 JU does provide these three pillars.

Knowledge of global market trends and industrial developments for clean hydrogen is essential to follow up and strengthen the leading position of EU organisations and is properly handled by the existing FCH 2 JU.

Around 70% of respondents to the Open Public Consultation indicated that the Institutionalised Partnership would significantly (positively) impact all listed categories in the area of science. The respondents who have indicated that the scope and coverage are not right, have indicated that it was too narrow more often than they viewed it as too broad.

¹⁷⁹ Thomas Reiss for the European Commission and Fraunhofer ISI (2016), Study on EU Positioning: An Analysis of the International Positioning of the EU Using Revealed Comparative Advantages and the Control of Key Technologies, https://ec.europa.eu/info/sites/info/files/research_and_innovation/groups/rise/final-report_eu-positioning.pdf

¹⁸⁰ As affirmed comprehensively in interviews with stakeholders from both research and industry institutions, Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe – Candidate Institutionalised European Partnership on Clean Hydrogen

Economic/Technological impacts

The baseline option could contribute to achieve technological impacts, for example by reducing the cost of hydrogen production. However, the lack of a community structure beyond the project consortia might limit the sharing and diffusion of experience among the key actors involved in hydrogen R&I¹⁸¹ and limit the coordination and collaboration necessary to address cross-border issues.¹⁸² In addition, this option will not significantly support the scaling up of ready-to-market applications as there is no clear mechanism to facilitate the bridge from R&D to market deployment¹⁸³ and it is assessed as more difficult for SMEs to access funding. This option would probably be less efficient in creating new networks or linking hydrogen and non-hydrogen players to potential partners dealing with complex projects than options with a community (e.g. energy intensive industry as potential end users, public transport operators, building owners and local or regional communities)..

A research agenda could be centrally defined under **Option 1**, so this Option could contribute to deploy hydrogen generation and infrastructures at scale. With a broader community than in the baseline option, this option can provide a collaborative framework which will contribute to bolster EU industry and can contribute to maintaining the competitiveness of industry and decarbonising heavy transport.¹⁸⁴ (score of +, see Table 5).

Thanks to the long term industrial commitment, **Option 2** allows high leverage of the private sector which is needed to finance expensive demonstrations. With a broad community, this option can contribute to maintaining the competitiveness of industry and to the decarbonisation of heavy transport. The community structure will also ensure the sharing and diffusion of experience among the key actors involved in hydrogen R&I. If well-coordinated with other funding and financing sources, this option can provide help for scaling up hydrogen applications ready-to-market (score of ++, see Table 5).

Stakeholder opinion

A thriving hydrogen economy can only be developed in Europe with the full backing of the European Commission and Member States. Stakeholders doubt whether hydrogen can be integrated into the EU's power, industry, and transport sectors if it loses institutionalised R&D support.

SMEs and research organisations in particular note the value of an institutionalised partnership in the hydrogen sector. The partnership allows smaller companies, which have developed niche products to serve growing hydrogen markets, to connect with larger industrial players that can support their development. The partnership allows research organisations to liaise with all potential partners, from research or from industry.

Around 80% of the respondents to the Open Public Consultation suggested the Institutionalised Partnership would have a significant (positive) effect on or be 'very relevant' for increasing industrial leadership in hydrogen technologies and the uptake of new technologies, for the provision of a solution for storing renewable energy for later use, and for the provision of low-carbon and competitive solutions for heavy duty and long-distance transport.

¹⁸¹ As affirmed comprehensively in interviews with stakeholders from both research and industry institutions.

¹⁸² As affirmed comprehensively in interviews with stakeholders from both research and industry institutions.

¹⁸³ Fuel Cell and Hydrogen 2 Joint Undertaking (2019), Hydrogen Roadmap Europe, available at <https://www.fch.europa.eu/news/hydrogen-roadmap-europe-sustainable-pathway-european-energy-transition>

¹⁸⁴ Joint Research Centre (2016), 4th International Workshop on Hydrogen Infrastructure and Transportation Report, <https://publications.jrc.ec.europa.eu/repository/bitstream/JRC103586/4%20int%20workshop%20on%20h2%20infra%20final%20pdfonline.pdf>

Societal impacts (including environmental, social, fundamental rights)

Continuous collaboration is needed to increase the maturity levels of transportation, industrial and building applications. **The baseline option**, given the short-term perspective of the calls, tends to support applications with short development timelines, meaning it could not enable all the opportunities the hydrogen economy could offer to support EU's climate goals. The capacity to reduce carbon emissions and pollution to air, water and soil would be rather limited under the baseline option since this is directly dependent on the ability to deploy at scale. Without knowledge management capacities to provide support to national, regional and local authorities, without the ability to support the increase of awareness and without the support to coordinate many stakeholders, this option would not be able to support the growth of a strong hydrogen ecosystem.

Compared to the baseline, Option 1, having a medium term perspective, would bring some of the opportunities the hydrogen economy offers to support EU's climate goals. Option 1 can contribute to build up knowledge capacity to support the hydrogen transition and can contribute to decarbonising hydrogen feedstock use by funding demonstration projects aiming to couple large renewable electricity production plants with hydrogen generation.^{185,186} (score of +)

Under **Option 2**, the strong community and network could bring together the required actors to build local or regional ecosystems, large transportation corridors and the related infrastructure that would connect producers and consumers¹⁸⁷. These efforts need a long-term commitment and vision for the hydrogen economy so that the EU can meet its climate targets. This option can support the building of capacities, by capitalising on experience, knowledge and expertise of a dynamic community of researchers and industrials from different sectors and on skills of an internal structure. Option 2 can also contribute to decarbonising hydrogen feedstock and it could also have an important impact regarding the market uptake (as explained under the economic impact) (score of ++).

None of the above options is expected to impact fundamental rights in the EU or abroad.

Directionality and additionality required

As regards the level of directionality and additionality required, **the baseline option** would not be able to facilitate the synchronised actions necessary to support policy objectives. Even if this option could ensure partial alignment with EU strategies, it would not be effective enough to significantly contribute to achieving them.

With the ability to prepare and implement a medium term plan **Option 1** could ensure compliance with EU and Member States strategies. However, a medium term clean hydrogen R&I agenda could only partially fit with the broader framework of a low carbon roadmap.

¹⁸⁵ European Commission and Hydrogen Europe (2019), Hydrogen for Climate Action: How to kick start the EU Hydrogen Industry to achieve the EU climate goals? –available at https://static1.squarespace.com/static/5d3f0387728026000121b2a2/t/5d9f23c486e0ee312c6380a7/1570710475026/Framework_H2+for+Climate+Action_final.pdf

¹⁸⁶ European Commission and Joint Research Centre (2019), Hydrogen use in EU decarbonisation scenarios, available at https://ec.europa.eu/jrc/sites/jrcsh/files/final_insights_into_hydrogen_use_public_version.pdf

¹⁸⁷ The [Green Hydrogen@Blue Danube IPCEI](#) project is a very good example of bringing together all actors along the whole value chain, involving many different actors. The institutionalised partnership is not an absolute necessity, but would be very helpful in networking

A long-term vision and strategy will be essential for hydrogen which is a versatile solution addressing many different sectors with continuously emerging applications. By involving research organisations, industry and the public sector, **Option 2** is considered as the most appropriate since it ensures a long-term commitment. Integrating the Strategic R&I Agenda into a broader spectrum is also essential. Option 2 will ensure a coherent approach for the whole hydrogen economy from R&I to market uptake, addressing in particular the “valley of death” challenge.

Stakeholder opinion

Hydrogen’s capacity to facilitate the decarbonisation of heavy industry and heavy transport within the EU is seen as its core strength. In order to fully decarbonise these sectors through hydrogen use, however, extensive development is still required. Stakeholders continuously argued that the partnership which most quickly and effectively can prompt the large-scale integration of hydrogen applications into Member States’ societies will be best positioned to contribute to the vital environmental goal of full decarbonisation of the EU by 2050.

The large majority of respondents to the Open Public Consultation considered the Institutionalised Partnership would be ‘very relevant’ to deliver on societal impacts with the exception for the category “improved working conditions”.

Table 5 summarises the scores assigned for each policy option, based upon the assessments above, as well as taking into account the support expressed by the different stakeholders.

Table 5: Overview of the options’ effectiveness compared to the baseline

	Baseline: Horizon Europe calls	Option 1: Co- programmed	Option 2: Institutionalised Article 187 TFEU
Scientific impact			
Hydrogen applications are more competitive, efficient and reliable	0	+	++
The EU maintains its leading position for cutting edge research and innovation in hydrogen applications	0	+	++
Economic/technological impact			
Through demonstration EU validates its ability to deploy economical hydrogen generation at scale	0	0	+
EU demonstrates its ability to deploy hydrogen infrastructures at scale	0	+	++
EU validates its ability to scale-up clean economical hydrogen end-use applications in heavy-duty transport and energy-intensive industries – maintaining global competitiveness	0	+	++
EU growth in hydrogen economy, especially for SMEs	0	+	++
Societal impact			
The EU’s maritime, aviation, rail and heavy-duty transport sectors, as well as its gas grid, can progressively decarbonise so the EU can meet its climate targets	0	+	++
Outdoor pollution can progressively decrease while reducing carbon emissions	0	+	++
Knowledge capacity built up to support the hydrogen transition, while increasing public support for additional hydrogen policy and regulatory frameworks	0	+	++

Notes: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.2. Efficiency

In order to compare the policy options consistently in terms of their efficiency, a standard cost model was developed for the external study supporting the impact assessment for the set of candidate Institutionalised Partnerships. The model and the underlying assumptions and analyses are set out in the Common Part of this impact assessment, Section 2.3.2 and in the Methodology Annex 4. A dedicated Annex 3 also provides more information on who is affected and how by this specific initiative in line with the Better Regulation framework. The scores related to the costs set out in this context allow for a “value for money” analysis (cost-effectiveness) in the final scorecard analysis in Section 6.4.

In addition, for this specific initiative under the baseline scenario of traditional calls, there would be winding down and social discontinuation costs for the existing implementation structure of the current Article 187 initiative. The impact assessment and Annex 3 in particular have estimated the costs of running an Institutionalised Partnership under Article 187 at € 2.9 million, corresponding to 27 full time equivalent staff. In contrast, the baseline (Horizon Europe calls) would rely on Horizon Europe structures and also require winding down the current JU Secretariat. Winding down costs would essentially be linked to the termination of existing contracts. As most of these contracts were already tied to the foreseen initial duration of the existing JU, the winding down costs are expected to be limited and much lower than the € 2.9 million recurring costs for the proposed Institutionalised Partnership. Overall it is estimated that the overall longer term cost savings from using traditional calls instead of an existing Article 187 initiative would considerably exceed the costs incurred for winding down operations. This overall situation is set as the starting point for the comparison of options. The score of this baseline scenario (traditional Horizon Europe calls) is set to 0 to be used as a reference point.

On this basis, the scores for the costs of the different options range from a value of 0, in case an option does not entail any additional costs compared to the baseline, to a score of (-) when an option introduces limited additional costs when compared to the baseline and a score of (-)(-) when substantial additional costs are expected in comparison with the baseline. In case the scores are lower than for the baseline scenario, (+) and (+)(+) are used.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy option – and the least cost-efficient – the Institutionalised Partnership option. Indeed, in terms of cost-efficiency, the Co-Programmed Partnership (Option 1) is 2 percentage points more efficient than the baseline and an Article 187 Partnership is 2 percentage points less cost-efficient than the baseline. This refers to the proportion of "total costs and investments" that is available to be spent on "R&I investment". These figures were estimated for the different forms of implementation, as described in the common part of the impact assessment. On the basis of this ratio, the baseline appears to be 2% more efficient than the Article 187 Institutionalised Partnership. The main differences between the costs structures of the various implementation forms are described in Annex 4, p. 52. A score of

(+) is therefore assigned for **cost-efficiency** to the Co-Programmed options and a score of (-) for the Institutionalised Partnership policy option¹⁸⁸.

Looking at cost-efficiency on the broader perspective of attracting higher level of investments from stakeholders, **Option 2 may appear much more cost-efficient**. The reason is a much higher total investment in R&I and a much higher contribution from the private actors (fact identified within the current FCH 2 JU, where for a flagship large-scale project like the “Hydrogen Valley” the contribution from the partners is three times higher than the Union contribution).

In the case of the current FCH 2 JU, the assessment of the contributions can be considered as an indication of the leverage achieved by EU funds and is clearly a strong sign that the JU is successfully aligned on industrial priorities¹⁸⁹. As mentioned in the Annual Activity report 2019, the FCH 2 JU has generated 2.24 of total leverage.

The majority of respondents to the Open Public Consultation indicated that it was very relevant to set up a specific legal structure for the partnership to achieve a more effective implementation of activities and to increase financial leverage, which is considered as a key element for the demonstration phase.

It should be noted that the potential for the creation of crowding-in effects for industry has been taken into account when assessing the effectiveness of the policy options.

Financial management of the existing FCH 2 JU, as stated in its interim evaluation, appears to be robust and the views of the public and beneficiaries sought in the consultations are strongly positive. The overall operational efficiency of the FCH 2 JU has improved as the institution has matured¹⁹⁰ in particular on budget execution level, commitment and payment appropriations, time to contract and time to payment. The proposed initiative will build on this strength.

Table 6: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Administrative, operational and coordination costs	0	(0)	(-)(-)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	(+)	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline.

¹⁸⁸ The baseline (traditional calls) is scored 0, as explained above.

¹⁸⁹ See section 1.3.3 of the present report

¹⁹⁰ See section 1.3.3 of the present report

6.3. Coherence

6.3.1. Internal coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with other actions, programmes and initiatives under Horizon Europe, in particular European Partnerships (internal coherence).

Baseline: Horizon Europe calls

Under this option, coherence between activities in the area of Clean Hydrogen with activities under Cluster 5 of Horizon Europe and the other initiatives presented in Figure 1 are ensured by the European Commission. However, exploitation of synergies between Clean Hydrogen and other initiatives, including exchanges of knowledge and experience between project teams and stakeholders, would require an additional level of coordination beyond Programme Committees. Option 0 could easily manage fundamental R&I activities. However, it is considered sub-optimal to address activities which need more coordination (for example demonstration activities) and closer collaboration between research, industry and decision-makers to define cohesive work plans.

Option 1: Co-Programmed European Partnership

Under the Co-Programmed option, synergies could be exploited more easily than under the baseline option. The European Commission could ensure coordination at the level of research agendas, while the Clean Hydrogen associations could proactively bring together projects and stakeholders from various initiatives to work together on common problems or tackle common challenges. However, as the Co-Programmed option does not promote a strong community or a network framework outside of project consortia, it is unlikely that it will establish an effective long-term framework and vision, nor increase cross-sector collaboration. Option 1 could better manage all types of R&I activities thanks to a better agenda setting pinpointing the climate and industrial priorities. However, Option 1 is not considered optimum to address the complex supply chains of hydrogen applications and the spread of actors. Its score would therefore be good compared to the baseline with +.

Option 2: Institutionalised European Partnership under Article 187 TFEU

The Institutionalised Article 187 partnership could provide for the highest level of coordination. The structure provides roles for the European Commission and for Clean Hydrogen associations, but it is built on a central coordination layer which can increase the effectiveness of its efforts. Since its management body organises the funding and implementation of projects, the Clean Hydrogen partnership could (together with other institutionalised partnerships) set concrete objectives and lay out a roadmap of activities and projects that can be implemented.

A dedicated management team responsible for the development of a long-term strategy and supporting work programmes for clean hydrogen RD&I would ensure that these are fully aligned with relevant strategies and programmes developed by other partnerships and initiatives within the EU research and innovation landscape. This would also enable the development of a shared vision and better exploitation of synergies from joint programmes and calls, in areas such as Clean Aviation, Battery Technology, Transforming EU's rail system, Clean Steel, Sustainable Process Industry (Process4Planet), waterborne sector (ZEWT), towards zero-emission road transport (2ZERO), Clean Energy Transition, and the power and the gas sectors. Option 2 would manage all TRLs related activities, from fundamental R&D up to market-readiness. Good knowledge management is also an asset

under this option - to allow the initiative to adequately assess projects in the selection process, to provide technical assistance where needed and even to challenge the industries in order to increase the speed of development. This would translate into a high score compared to the baseline set at ++.

Stakeholder opinion

Stakeholders overwhelmingly argue that only through an institutionalised partnership can all necessary actors be involved, the ideal range of activities undertaken, and the strategic directionality be designed and implemented as required. They agree that if an institutionalised partnership were not pursued, vital stakeholders would be left out of important conversations, an inadequate/partial range

Respondents to the Open Public Consultation, when asked if it would be possible to rationalise the candidate European Institutionalised Partnership and its activities and/or better link it with other comparable initiatives, indicated that they think rationalisation and linking with other sectors are important. The respondents think the initiative could be linked with other comparable initiatives related to hydrogen, renewable energy and the application of hydrogen as well as clean aviation and rail systems.

of activities and projects would be funded, and the strategic directionality established would lack clarity and vision.

6.3.2. External coherence

In this section we assess the extent to which the policy options show the potential of ensuring and maximising coherence with their external environment, including EU-level programmes and initiatives beyond the Framework Programme and/or national and international programmes and initiatives, but as well as with overarching framework conditions, such as regulation, standardisation, etc. (external coherence).

Baseline: Horizon Europe calls

In absence of a clear engagement with relevant stakeholders, this option would not be helpful for putting together market uptake mechanisms outside the R&I sphere for the applications developed to market readiness where these are needed (e.g. buses, fuel cells, electrolysers, ...). Despite that under this option, some coordination with other European Commission activities is possible at the level of priorities, coordination at the level of implementation is somewhat limited or even not feasible. In addition, this option typically remains focused on the EU27 alone. International organisations play an important role in the development of clean hydrogen. However, the baseline option does not allow for implementation of a coherent international cooperation strategy. In addition, this option would not support motivating additional Member State participation, where increasing their involvement to ensure alignment with their own R&D agendas and low carbon roadmaps is essential.¹⁹¹ Finally, collaboration with national or regional initiatives such as national programmes for the support of Clean Hydrogen or the coordination with regional clusters is not feasible under this option.

Option 1: Co-Programmed European Partnership

Under this option, the European Commission can contribute to some extent to the coordination with European non-FP initiatives at the level of the strategy. The non-

¹⁹¹Fuel Cell and Hydrogen 2 Joint Undertaking (2019), Hydrogen Roadmap Europe, available at <https://www.fch.europa.eu/news/hydrogen-roadmap-europe-sustainable-pathway-european-energy-transition>

systematic participation of Member States provides the opportunity for coordination with the national programmes and initiatives and the regional clusters. Member States and Clean Hydrogen associations could coordinate with the national and industry efforts to ensure alignment with their own R&D agendas and low carbon roadmaps and fully engage in the Clean Hydrogen IPCEI. Score would therefore be good compared to the baseline with +.

Option 2: Institutionalised European Partnership under Article 187 TFEU

This option ensures continuous dialogue among all players, including international, national, regional and local authorities and therefore does provide a clear global framework which would be necessary to mainstream clean hydrogen RD&I efforts into a global low carbon roadmap.¹⁹² But this option does not focus on the engagement of Member States and will need to take care to involve them all. MS should not be forced to join the hydrogen R&D dynamic but should be convinced of its strategic importance. Experience-sharing platforms would therefore be relevant and powerful. This option would be the most relevant to set up such a framework and ensure its large diffusion. Furthermore, this option, with the direct involvement of the EC and Member States, could facilitate the development of an effective, cross-sectoral, cross-border governance model necessary to enable agile rollout of hydrogen applications, and to open broader markets to these technologies. Finally, under this option, the possibilities of coordination and exploitation of synergies offered by the Co-Programmed option are expanded by the existence of the central coordination level which can improve and extend the collaboration at the level of projects. This would translate into a high score compared to the baseline with ++.

Stakeholder opinion

Many stakeholders who are also interested in/involved with other candidate partnerships believe that strongly coordinated efforts between partnerships and other EU programmes will be required to ensure external coherence. They argue that an institutionalised partnership with a dedicated coordination function is the best way to ensure that unnecessary overlap is avoided while potential synergies are properly exploited.

The initiative should operate at a global level, or at least be connected to all relevant counterparts to ensure compliance with international standards, to secure the role of EU industry in different hydrogen spaces, and to ensure that regulatory issues are addressed properly. As affirmed comprehensively in interviews with stakeholders from both research and industry, an institutionalised partnership is probably the most appropriate initiative to foster collaboration at international levels, given its expertise and knowledge management.

For some **EU13 national associations interviewed**, Member States would expect more international collaboration and more involvement in EU calls in order to align Clean Hydrogen with their national low carbon strategies, including funding policies.

Table 7, below, lists the scores assigned for each of the policy options, based upon the assessments above, as well as taking into account the views expressed by the different stakeholders.

Regarding **internal coherence**, synergies and coherence (ensured by the European Commission) between Clean Hydrogen and other initiatives would require an additional level of coordination than provided by the baseline option. The Co-Programmed option

¹⁹² European Commission and Hydrogen Europe (2019), Hydrogen for Climate Action: How to kick start the EU Hydrogen Industry to achieve the EU climate goals? –available at https://static1.squarespace.com/static/5d3f0387728026000121b2a2/t/5d9f23c486e0ee312c6380a7/1570710475026/Framework_H2+for+Climate+Action_final.pdf

would be able to provide this coherence, but it will unlikely establish an effective long-term framework and vision, nor increase cross-sector collaboration. Therefore, the institutionalised partnership would allow for greater internal coherence than the two other options, expanding the possibilities of coordination and exploitation of synergies offered by the Co-Programmed option by the existence of the central coordination level.

Regarding the **external coherence**, the baseline option and the co-programmed partnership are assessed to be less successful than an institutionalised partnership in creating the required systemic effects. This is due to their weaknesses in addressing the international community, ensuring adequate coordination with other programmes, third countries and international organisations, aligning with their own R&D agendas and low carbon roadmaps, and for facilitating market uptake support to be put in place. Therefore, the institutionalised partnership would allow for greater external coherence than the two other options.

Table 7: Overview of the options’ potential for ensuring and maximizing coherence

	Option 0: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Internal coherence	0	0/+	++
External coherence	0	+	++

Notes: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline.

6.4. Tabular comparison of options and identification of preferred option

Building upon the outcomes of the analysis, this section presents a comparison of the options’ ‘performance’ against the dimensions of effectiveness, efficiency and coherence.

Table 8: Overall scorecard of the policy options for all criteria

	Criteria	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Institutionalised Article 187 TFEU
Effectiveness	Scientific impacts			
	Hydrogen applications are more competitive, efficient and reliable	0	+	++
	The EU maintains its leading position for cutting edge research and innovation in hydrogen applications	0	+	++
	Economic/technological impacts			
	Through demonstration EU validates its ability to deploy economical hydrogen generation at scale	0	0	+
	EU demonstrates its ability to deploy hydrogen infrastructures at scale	0	+	++
	EU validates its ability to scale-up clean economical hydrogen end-use applications in heavy-duty transport and energy-intensive industries – maintaining global competitiveness	0	+	++
	EU growth in hydrogen economy, especially for SMEs	0	+	++
	Societal impacts			
	The EU’s maritime, aviation, rail and heavy-duty transport sectors, as well as its gas grid, can progressively decarbonize so the EU can meet its climate targets	0	+	++
	Outdoor pollution can progressively decrease while reducing carbon emissions	0	+	++
	Knowledge capacity built up to support the hydrogen transition while increasing public support for additional hydrogen policy and regulatory frameworks increases	0	+	++

Coherence	Internal coherence	0	0/+	++
	External coherence	0	+	++
Efficiency	Overall cost	0	0	--
	Adjusted cost-scoring	0	+	-

Notes: Scores for effectiveness and coherence: Score ++: Option presenting a *high* potential compared to baseline; Score +: Option presenting a *good* potential compared to baseline; Score 0: Potential of the baseline. Scores for efficiency: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared with the baseline; score (-)(-) = substantial additional costs compared with the baseline

Box 2 Comparison between the preferred option & the current partnership existing in the area taking into account lessons from past evaluations

What continues	What is different
<ul style="list-style-type: none"> • Art 187 Union Body, with EC, Hydrogen Europe and Hydrogen Europe Research as founding members • Blending of funds for large demonstration projects: Horizon, CEF • Members contributing to running costs of the JU • Preparation of Multiannual and Annual Work Programmes based on Strategic Research and Innovation Agenda • Management of evaluation calls and running projects 	<ul style="list-style-type: none"> • Enlargement of the scope of the initiative addressing the entire value-chain from production to end-use of hydrogen • Better member state involvement/ renewed role of state representative group • Actions to increase wider participation from all EU 27 • Potentially higher leverage of private investment • Higher impact of investments due to closer links with industrialisation/ market uptake (e.g. the proposed Clean Hydrogen Alliance) • Better synergies with other Horizon Europe, national and regional initiatives

Overall the implementation of the Clean Hydrogen initiative through an **institutionalised partnership established under Article 187 of TFEU is the preferred option** as it would best ensure that private and public sectors remain fully engaged in the development and implementation of a long-term strategy for clean hydrogen R&I. It is also consistent with the aim of leveraging industrial financial and in-kind resources, such that the impact of funding provided by the Commission is maximised. This form of partnership would continue to provide a stable framework for encouraging the participation of organisations from all concerned sectors (including those outside the hydrogen industry), securing and allocating resources, managing a wide range of RD&I projects across all TRLs and creating synergies with other partnerships and initiatives within and outside the Climate, Energy and Mobility cluster. It is also considered appropriate to develop a strategy for hydrogen that is fully aligned with European Green Deal priorities, and especially the European climate commitment, and with several sustainable development goals.

7. THE PREFERRED OPTION - HOW WILL ACTUAL IMPACTS BE MONITORED AND EVALUATED?

7.1. The preferred option

- In Table 9, below, the alignment of the preferred option of Institutionalised European Partnership under Article 187 TFEU with the selection criteria for European Partnerships defined in Annex III of the Horizon Europe Regulation is depicted.

Seeing that the design process of the candidate Institutionalised Partnerships is not yet concluded and several of the related topics are still under discussion such as finalisation of Strategic Research and Innovation Agenda, Governance of the proposed partnership, partners signing up to final, commonly agreed objectives and committing the resources and investments needed from their side to achieve them, e.g. partners' financial contribution, the criteria of additionality/directionality and long-term commitment are covered in terms of *expectations* rather than ex-ante demonstration.

Table 9: Alignment with the selection criteria for European Partnerships

Criterion	Alignment of the preferred option
Higher level of effectiveness	<p>As demonstrated in Chapter 6, an institutionalised partnership would be considerably more effective in addressing global challenges and delivering research and innovation objectives, in securing EU competitiveness and, where relevant, in contributing to international commitments (e.g. on standards).</p> <p>The institutionalised partnership would also be effective in securing sustainability (the final goal of “clean” hydrogen) and in strengthening the European Research and Innovation Area.</p>
Coherence and synergies	<p>A dedicated management structure similar to the Programme Office in current FCH 2 JU, responsible for the development of a long-term strategy and supporting work programmes for clean hydrogen RD&I, would ensure that these are fully aligned with relevant strategies and programmes developed by other partnerships and initiatives within the EU research and innovation landscape. This would also enable the development of a shared vision and better exploitation of synergies from joint programmes and calls, in areas such as Clean Aviation, Transforming EU's rail system, Clean Steel, Sustainable Process Industry (Process4Planet), waterborne sector (ZWET), towards zero-emission road transport (ZZERO), Clean Energy Transition, and the power and the gas sectors.</p> <p>A dedicated management structure would also ensure proper coordination and complementarity with European Union, local, regional, national and, where relevant, international initiatives on hydrogen or other partnerships and missions.</p>
Transparency and openness	<p>As demonstrated in Chapter 6, an institutionalised partnership would be better placed to identify priorities and objectives in terms of expected results and impacts, in involving partners and stakeholders from across the entire clean hydrogen value chain, from different sectors, backgrounds and disciplines, including international ones when relevant.</p> <p>SMEs would have the most appropriate support from the partnership. A dedicated management structure would also be able to put into place clear modalities for promoting participation of SMEs and for disseminating and exploiting results,</p> <p>An institutional partnership would ensure that the outputs of RD&I programmes are transparent and available to stakeholders inside and outside the hydrogen community. The framework governing participation would allow any organisation meeting defined criteria to participate, in an open and transparent way. This framework could provide support and guidance, help networking and build up consortia when addressing complex projects throughout the whole value chain.</p>
Additionality and directionality	<p>As demonstrated in chapter 6, an institutionalised partnership would be much better placed to define a common strategic vision of the purpose of the European Partnership, in demonstrating expected qualitative and significant quantitative leverage effects, including a method for the measurement of key performance indicators and in creating synergies within the EU research and innovation landscape.</p> <p>An institutionalised partnership would be able to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level.</p>
Long-term commitment	<p>In the case of institutionalised European Partnerships, established in accordance with article 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments</p>

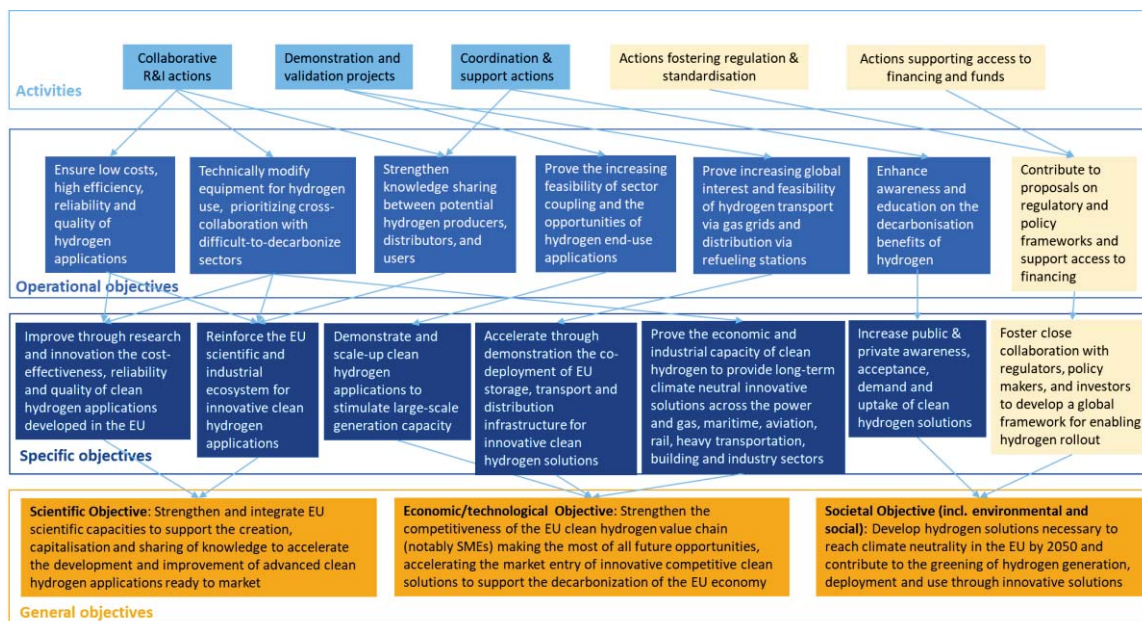

7.2. Objectives and corresponding monitoring indicators

7.2.1. Operational objectives

Several operational objectives have been identified which would enable the partnership to achieve its specific objectives, as shown in Figure 10 below.

The figure also lists a range of actions and activities, going beyond R&I that can be implemented under Horizon Europe (which are highlighted in yellow). This reflects the definition of European Partnerships in the Horizon Europe Regulation as initiatives whereby the Union and its partners “commit to jointly support the development and implementation of a programme of research and innovation activities, including those related to market, regulatory or policy uptake.”

Figure 10: Operational objectives of the initiative

7.2.2. Monitoring indicators

In addition to Key Impact Pathways indicators set centrally in the Regulation of Horizon Europe, additional monitoring indicators have been identified to enable the tracking of progress of the partnership towards meeting its objectives. These are shown in Table 9.

Table 9: Monitoring indicators in addition to the Horizon Europe key impact pathway indicators

	Short-term (typically as of year 1+)	Medium-term (typically as of year 3+)	Long-term (typically as of year 5+)
Scientific impact	Number of projects resulting in one or more journal citations	Number of times that journal citations generated by the partnership are cited in the global literature	Number of publications registered by the clean hydrogen industry and research organisation located in Europe Number of staff transferring between research-based institutions & industry
Technological / economic impact	Number of projects involving organisations outside the hydrogen industry Number of projects with a documented strategy identifying the potential application of results to	Number of projects leading to validated demonstration of clean hydrogen applications Number of clean hydrogen pilots demonstrating readiness	Number of patents registered by the clean hydrogen industry and research organisation located in Europe Number of projects conducting market uptake Time for clean hydrogen pilots demonstrating readiness for market

	<p>defined market needs</p> <p>Number of projects resulting in increasing clean hydrogen application's TRLs</p> <p>Number of individuals working on projects initiated by the partnership</p>	<p>for market uptake</p> <p>Number of years for programmed projects to reach TRL 8</p> <p>Number of mature clean hydrogen applications</p> <p>Number of occupied and advertised jobs in clean hydrogen</p>	<p>uptake</p> <p>Value of exports generated by the European hydrogen sector</p> <p>Direct and indirect employment generated by the European clean hydrogen economy</p> <p>Costs of clean hydrogen production</p> <p>Costs of clean hydrogen distribution</p> <p>Price of hydrogen based solutions compared to alternatives</p>
<p>Societal impact Incl. Environmental impact</p>	<p>Number of projects developing sector specific low carbon solutions, including the large public</p>	<p>Level and intensity of the hydrogen-related R&I (in percentage of turn-over)</p> <p>Number of projects focussing on hard to decarbonise sectors</p>	<p>Changes in local outdoor air pollution</p> <p>Changes in public acceptance of clean hydrogen solutions</p> <p>Evolution in CO₂ emissions reduction in relevant sectors</p>

7.2.3. Evaluation framework

The evaluation of the Partnership will be done in full accordance with the provisions laid out in Horizon Europe Regulation Article 47 and Annex III, with external interim and ex-post evaluations feeding into the overall Horizon Europe evaluations. As set in the criteria for European Partnerships, the evaluations will include an assessment of the most effective policy intervention mode for any future action; and the positioning of any possible renewal of the Partnership in the overall European Partnerships landscape and its policy priorities. In the absence of renewal, appropriate measures will be developed to ensure phasing-out of Framework Programme funding according to conditions and timeline agreed with the legally committed partners ex-ante.

2. ORGANISATION AND TIMING

Institutionalised partnerships are foreseen in Articles 185 and 187 of the Treaty on the Functioning of the European Union (TFEU). The preliminary agreement on Horizon Europe contained a list of possible areas for institutionalised partnerships based on Article 185 and 187. For each of these areas the Commission considered 12 potential institutionalised partnerships. Their set up involves new EU legislation and the establishment of dedicated implementing structures and therefore an impact assessment for each of these initiatives.

Following political validation in June 2019, the impact assessment process started with the publication of inception impact assessments for each initiative in August 2019.

An inter-service steering group (ISSG) on research and innovation partnerships under Horizon Europe was set up in May 2019 and held 4 meetings before submission of the Staff Working Document to the Regulatory Scrutiny Board (7 May 2019, 19 June 2019, 5 December 2019, 20 January 2020). The ISSG consisted of representatives of the Secretariat-General, Directorate-General for Budget, Directorate-General for Research and Innovation, Directorate-General for Communications Networks, Content and Technology, Directorate-General for Mobility and Transport, Directorate-General for Internal Market, Industry, Entrepreneurship and SMEs, Directorate-General for Energy, Directorate-General for Environment, Directorate-General for Climate Action, and the Legal Service.

An online public stakeholder consultation was launched between September and November 2019, gathering 1635 replies for all 12 initiatives.

3. CONSULTATION OF THE RSB

Two upstream meetings with the Regulatory Scrutiny Board were held on 10 July 2019 and 30 September 2019.

In accordance with the feedback received from the Regulatory Scrutiny Board on 27.03.2020 the Staff Working Document has been revised as presented in Figure 1. The impact assessment was endorsed by the Inter Service Steering Group on 20.01.2020.

4. EVIDENCE, SOURCES AND QUALITY

To ensure a high level of coherence and comparability of analysis for all candidate initiatives, an external study was procured to feed into the impact assessments of the 12 candidate institutionalised partnerships¹. It consisted of an horizontal analysis and individual thematic analyses for each of the initiatives under review.

¹ Technopolis Group, 2020, forthcoming.

For all initiatives, the evidence used includes desk research partly covering the main impacts and lessons learned from previous partnerships. A range of quantitative and qualitative data sources complement the evidence base, including evaluations; foresight studies; statistical analyses of Framework Programmes application and participation data and Community Innovation Survey data; analyses of science, technology and innovation indicators; reviews of academic literature; sectoral competitiveness studies and expert hearings. The analyses included a portfolio analysis, a stakeholder and social network analysis in order to profile the actors involved as well as their co-operation patterns, and an assessment of the partnerships' outputs (bibliometrics and patent analysis). A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options. Public consultations (open and targeted) supported the comparative assessment of the policy options. For each initiative up to 50 relevant stakeholders were interviewed by the external contractor (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others). In addition, the analysis was informed by the results of the Open Public Consultation (Sep – Nov 2019), the consultation of the Member States through the Strategic Programme Committee and the online feedback received on the Inception Impact Assessments of the set of candidate Institutionalised European Partnerships.

A more detailed description of the methodology and evidence base used, completed by thematic specific methodologies, is provided in Annexes 4 and 6.

Figure 1 Modifications to the draft Staff Working Document based on comments received from the Regulatory Scrutiny Board

Comments from the Regulatory Scrutiny Board	Actions taken for the Staff Working Document
<p>(1) The report does not adequately explain how greater flexibility in implementation of research projects relates to the desire to focus research. It does not sufficiently describe the competition aspects of the partnership.</p>	<p>For hydrogen, we are talking today about a very dynamic sector and community. Responsiveness to new technological developments is essential, meaning that it should be ensured that the partnership would be able to react quickly and efficiently and that the Clean Hydrogen initiative is empowered enough to deliver.</p> <p>Explanations are provided in p.44 and p.45. A number of activities have been mentioned in the IA to ensure flexibility of implementation and create the expected impacts such as (i) Seek synergies with R&I programmes of other sectors and initiatives (ii) Coordinate R&I actions ranging from concept to demonstration and validation activities (covering all Technology Readiness Levels), ensuring inclusion of new actors and integration of extended value chains (iii) Develop deployment and piloting activities to ensure flexibility over time across the range of applications implemented and (IV) Co-</p>

	<p>create solutions with end-users, emphasising the importance of flexibility in addressing different target groups over time, including industrial end users for which low carbon alternatives are not evident.</p> <p>The request of flexibility or responsiveness in terms of implementation of the Clean Hydrogen Partnership is fully aligned with the call for an enlarged research agenda, addressing production, distribution and storage as indicated in p.40.</p> <p>The calls for research and innovation proposals in the partnership will be open to all and not restricted to just members of the associations Hydrogen Europe and Hydrogen Europe Research. The partnership will fund and manage cooperative research projects where different industrial and research entities will conclude a consortium agreement on how they will share foreground and background IPR.</p>
<p>(2) The report should explain in more detail the current partnership, its objectives and its structure.</p>	<p>Additional information is provided on p.26.</p> <p>The objectives of FCH 2 JU, organised around the energy and transport pillars were the following:</p> <ul style="list-style-type: none"> - <u>Clean Transport</u> : reduce fuel cell system costs for transport applications - <u>Green hydrogen production</u>: increase efficiency and reduce costs of hydrogen production, mainly from water electrolysis and renewables - <u>Heat & electricity production</u>: increase fuel cell efficiency and lifetime - <u>Hydrogen storage for grid balancing</u>: demonstrate on a large-scale hydrogen's capacity to harness power from renewables and support its integration into the energy system - <u>Minimal use of critical raw materials</u>: reduce platinum loading <p>FCH 2 JU is a public-private partnership with 3 members: the industry grouping Hydrogen Europe, the research grouping Hydrogen</p>

	Europe Research and the European Commission.
<p>(3) The report does not adequately describe the existing partnership, including its strengths and weaknesses.</p> <p>The report should use the findings of the evaluation of the existing Joint Undertaking to explain the need for change. It should justify the shift of focus to hydrogen production, distribution and storage in the new partnership.</p>	<p>Information is provided on p.26 and p.27. Strengths under the new headings “What has or is being achieved so far” and weaknesses under “What are the key areas for improvement & unmet challenges”.</p> <p>Explanation is provided on p.40. The shift of focus to hydrogen production, distribution and storage in the new partnership is justified by the evolution of the political context with the role of hydrogen likely to become more prominent in a fully decarbonised energy system and the European Green Deal, the new growth strategy that aims to transform the EU into a fair and prosperous society, with a modern, resource-efficient and competitive economy, where there are no net emissions of greenhouse gases in 2050 and where economic growth is decoupled from resource use.</p> <p>Reaching this long term vision means capacity to supply hydrogen at scale and simultaneously boosting demand.</p>
<p>(4) The report does not clearly identify which problems and problem drivers the initiative would address.</p> <p>The report should limit the problems and problem drivers to what research and innovation actions can address. It could clarify how wider problems are addressed by other initiatives.</p>	<p>On Figure 8 p. 30 “Problem tree behind an initiative for European research and innovation on Clean Hydrogen”, issues relevant to research and innovation actions are highlighted in boxes in blue.</p> <p>Chapter 2 of the report, in particular sections 2.1 and 2.2 now better define what research and innovation actions will address.</p> <p>Inadequate or not fit for purpose regulatory, policy and financial framework for clean hydrogen are addressed in the Hydrogen Strategy and the global framework for enabling hydrogen rollout will be central to the Clean hydrogen Alliance to be launched as announced in the New Industrial Strategy.</p>
<p>(5) In this framework, the report should justify why continuation of the current partnership is not the baseline. The report should use its selected baseline (Horizon</p>	<p>See p.14, In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made compared to the</p>

<p>Europe calls) consistently throughout the report, notably in the impact analysis and in the comparison of the policy options. The report sometimes takes the absence of any research programme as a baseline. The selected baseline should consistently be scored as zero, while the scoring of the other options should be adjusted to reflect their impacts as compared to the baseline.</p>	<p>baseline. Therefore, for each of these aspects <u>the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point.</u></p> <p>A new Table 5: Overview of the options' effectiveness compared to the baseline is provided on p.53.</p>
<p>(6) The report should clarify how the flexibility of a partnership, in particular via changes to its membership, is compatible with the narrower focus on research areas and with potential risks of excluding competitors. It should reflect on the consequences of partners not being willing to accept newcomers to avoid that competitors take advantage of their earlier investments. The report should clarify the changes in the substance of cooperation by moving from research to production and distribution. It should reflect on how to avoid anti-competitive behaviour in product markets.</p>	<p>See point (1) above and paragraphs 4.3.1 and 4.3.2 on p.44 and p.45</p> <p>Despite the potential of hydrogen to contribute to the decarbonisation of many different sectors, one has to acknowledge that the deployment of hydrogen and fuel cells is only marginal today (see Annex 6). As a consequence, there is no evidence of anti-competitive behaviour from the side of partners or in product markets. To accelerate the commercial readiness of hydrogen technologies, the proposed Clean Hydrogen Partnership is building on the work of FCH 2 JU which made the start of commercialisation of a first series of applications possible. It will aim at bringing a second series of applications to commercial level in particular in industry heat and feedstock, power generation and hard to abate transport sectors.</p> <p>Considering the substance of cooperation, the partnership seek to address research and innovation aspects related to production, distribution, infrastructure and storage of hydrogen. As such, it is open to newcomers as mentioned in p.44, paragraph 4.3.1 "Type and composition of actors to be involved". Clean hydrogen partnership is the R&I pillar of the overall hydrogen strategy.</p>
<p>(7) The report should provide – as far as possible – quantified estimates of the cost of the different partnership types. This would provide evidence for the assessment that cost differences between policy options matter less than differences in benefits. The report should also take into account savings or costs stemming from the continuation or</p>	<p>See revised paragraph 6.2 Efficiency in p.53 and p.54.</p> <p>A common approach was taken to assess the costs of the various policy options in general terms. The main purpose of this common approach was to show – in relative terms - how the costs of e.g. traditional calls compare</p>

<p>discontinuation of various elements of the already existing partnership in the baseline and policy options.</p>	<p>with those of an institutionalised partnership in general.</p> <p>Further refinements in these costs are made in the individual assessment, for instance if one would have to hypothesize discontinuation costs for an existing Partnership. Conversely, the benefits are specific to each case and reflect the expected impacts of the Partnership. Where some monetised figures were available, these have been included in Annex 3.</p> <p>The overall message however, is that the costs difference are not the driving factors for choosing between the various options, but it is rather the type of benefits that the different forms of implementation could bring about that justify the choice.</p>
<p>(8) The report should explain the choice of the specific objectives (in particular the origin of the quantified targets) and clarify the relation between the objectives, the “expected impacts” and the “functionalities”. Impacts should be assessed with respect to the specific objectives.</p>	<p>Due to the flexibility and versatility of hydrogen and multitude of hydrogen end-use applications, defining overall time-bound targets was not straightforward. In order to achieve the general objectives, seven specific objectives were defined in the IA from which three “time-bound targets” were mentioned on p.40 and p.41:</p> <ul style="list-style-type: none"> • Deliver hydrogen based solutions at a price equivalent to the alternatives by 2030. • Produce clean hydrogen at a cost of ~€1.5-3/kg by 2030, allowing penetration into mass markets. • Reduce the distribution costs to less than €1/kg of hydrogen at scale by 2030 <p>These time-bound targets can already be considered as operational objectives.</p> <p>These objectives in terms of costs are very ambitious considering in particular that the actual cost of clean hydrogen delivered today at Hydrogen refuelling station is on average close to € 9-12/kg. Similar comments could be made for fuel cells components and stacks which are today still very expensive -</p>

	<p>meaning that efforts should be made to reduce costs by funding R&I activities seeking for example to reduce the amount of critical elements (Platinum group metals) while improving energy density, efficiency and durability.</p> <p>Production costs of clean hydrogen are linked to Electrolyser costs. Those have already been reduced by 60% in the last ten years, and are expected to halve by 2030 compared to today with economies of scale.² In areas with low-cost renewable electricity, electrolysers are expected to be able to compete with fossil-fuel hydrogen in 2030.</p> <p>On distribution costs, transport costs can vary dramatically between transport means (e.g. pipeline (15 cents/kg) versus trucks versus liquid carriers, etc....) and context of usage. The figure of “less than 1 euro” is for the specific case of transport by truck for mobility application.</p> <p>Given the focus of the impact assessment on comparing different forms of implementation, the identification of “key functionalities needed” allows making the transition between the definition of the objectives and what would be crucial to achieve them <i>in terms of implementation</i>. These functionalities relate to the type and composition of actors that have to be involved, the type of range of activities that should be performed, the degree of directionality needed and the linkages needed with the external environment. A paragraph is inserted in 4.4.</p>
<p>(9) The report should be more transparent about what issues remain open after the impact assessment and will be decided at a later stage, because of the particularities of this exercise where some contextual elements,</p>	<p>Issues that remain open after the impact assessment are now listed on p. 60.</p> <p>These are the followings:</p> <ul style="list-style-type: none"> - Finalisation of Strategic Research and

² Based on cost assessments of IEA, IRENA and BNEF. Electrolyser costs to decline from EUR 900/kW to EUR 450/KW or less in the period after 2030, and EUR 180/kW after 2040. Costs of CCS increases the costs of natural gas reforming from EUR 810/kWh2 to EUR 1512/kWh2. For 2050, the costs are estimated to be EUR 1152/kWh2.

<p>such as the budget, remain undecided. For example, the report refers to certain selection criteria that will be addressed later.</p> <p>The Board notes the estimated costs and benefits of the preferred option in this initiative, as summarised in the attached quantification tables.</p>	<p>Innovation agenda which will provide a detailed description of activities to be performed in the partnership.</p> <ul style="list-style-type: none"> - Governance of the proposed partnership - Partners signing up to final, commonly agreed objectives and committing the resources and investments needed from their side to achieve them, e.g. partners' financial contribution. - Finalisation of the Basic Legal Act.
--	---

Annex 2 Stakeholder Consultation

1. OVERVIEW FOR ALL CANDIDATE INSTITUTIONALISED EUROPEAN PARTNERSHIPS

1.1. Introduction

In line with the Better Regulation Guidelines,³ the stakeholders were widely consulted as part of the impact assessment process of the 12 candidates for institutionalised partnerships, including national authorities, the EU research community, industry, EU institutions and bodies, and others. These inputs were collected through different channels:

- A feedback phase on the inception impact assessments of the candidate initiatives in August 2019, gathering 350 replies for all 12 initiatives on the “Have your say” web portal during a period of 3 weeks;
- A structured consultation of Member States performed by the EC services over 2019 through the Shadow Strategic Configuration of the Programme Committee of Horizon Europe (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.
- An online public stakeholder consultation administered by the EC, based on a structured questionnaire, open between September and November 2019, gathering 1635 replies for all 12 initiatives;
- A targeted consultation run by the external study contractors with a total of 608 interviews performed as part of the thematic studies by the different study teams between August 2019 and January 2020.

1.2. Horizontal results of the Open Public Consultation

The consultation was open to everyone via the EU Survey online system.⁴ The survey contained two main parts to collect views on general issues related to European partnerships (in Part 1) and specific responses related to one or more of the 12 candidate initiatives (as selected by a participant). The survey was open from 11 September till 12 November 2019. The consultation was available in English, German and French and advertised widely through the European Commission’s online channels as well as via various stakeholder organisations.

1.2.1. Profile of respondents

In total, 1635 respondents filled in the questionnaire of the open public consultation. Among them, 272 respondents (16.64%) were identified to have responded to the consultation as part of a campaign (coordinated responses). Based on the Better Regulation Guidelines, the groups of respondents where at least 10 respondents provided coordinated answers were labelled as ‘*campaigns*’, segregated and analysed separately and from other responses. In total 11

³ https://ec.europa.eu/info/files/better-regulation-guidelines-stakeholder-consultation_en

⁴ <https://ec.europa.eu/eusurvey/runner/ConsultationPartnershipsHorizonEurope>

campaigns were identified, the largest of them includes 57 respondents⁵⁵. In addition, 162 respondents in the consultation also display similarities in responses but in groups smaller than 10 respondents. Hence, these respondents were not labelled as campaigns and therefore were not excluded from the general analysis.

Table 1: Country of origin of respondents (N=1635)

Country	Number of respondents	Percentage of respondents
Germany	254	15.54%
Italy	221	13.52%
France	175	10.70%
Spain	173	10.58%
Belgium	140	8.56%
The Netherlands	86	5.26%
Austria; United Kingdom	61	3.73%
Finland	49	3.00%
Sweden	48	2.94%
Poland	45	2.75%
Portugal	32	1.96%
Switzerland	28	1.71%
Czechia	24	1.47%
Greece	23	1.41%
Norway; Romania	22	1.35%
Denmark	20	1.22%
Turkey	19	1.16%
Hungary	14	0.86%
Ireland	12	0.73%
United States	11	0.67%
Estonia; Slovakia; Slovenia	10	0.61%
Bulgaria; Latvia	9	0.55%
Bosnia and Herzegovina	7	0.43%
Lithuania	4	0.24%
Canada; Croatia; Israel	3	0.18%
China; Ghana; Iceland; Japan; Luxembourg; Morocco	2	0.12%
Bhutan; Botswana; Cyprus; Iran; Malta; Mexico; Moldova; Mongolia; Palestine; Russia; Serbia; South Africa; Tunisia; Ukraine; Uruguay	1	0.06%

As shown in Figure 2, the three biggest **categories of respondents** are representatives of companies and business organisations (522 respondents or 31.9%), academic and research institutions (486 respondents or 29.7%) and EU citizens (283 respondents or 17.3%). Among the group of respondents that are part of campaigns, most respondents are provided by the same groups of stakeholders, namely company and business organisations (121 respondents or 44.5%), academic and research institutions (54 respondents or 19.8%) and EU citizens (42 respondents or 15.4%).

⁵⁵ The candidate Institutionalised Partnership Clean Hydrogen has the highest number of campaigns, namely 5. A few initiatives, such as Innovative SMEs, Smart Networks and Systems, were not targeted by campaigns. Some campaign respondents decided to provide opinions about several partnerships.

Figure 2 Type of respondents (N=1635) - For all candidate initiatives

Among all consultation respondents, 1303 (79.69%) have been **involved in the on-going research and innovation framework programme** Horizon 2020 or the preceding Framework Programme 7, while 332 respondents (20.31%) were not. In the group of campaign respondents, the share of those who were involved in these programmes is higher (245 respondents out of 272 or 90.07%) than in the group of non-campaign respondents (1058 out of 1363 or 77.62%). When respondents that participated in the Horizon 2020 or in the preceding Framework Programme 7 were asked to indicate in which capacity they were involved in these programmes, the majority stated they were a beneficiary (1033 respondents) or applicant (852 respondents). The main stakeholder categories, e.g. companies/business organisation, academic/research institutions, etc., show a similar distribution across the capacities in which they ‘have been involved in Horizon 2020 or in the Framework Programme 7’ as the overall population of consultation respondents.

Among those who have been involved in Horizon 2020 or the preceding Framework Programme 7, 1035 respondents (79.43%) are/were **involved in a partnership**. The share of respondents from campaigns that are/were involved in a partnership is higher than for non-campaign respondents, 89.80% versus 77.03% respectively. The list of partnerships under Horizon 2020 or its predecessor Framework Programme 7 together with the numbers, percentages of participants is presented in Table 4 **Error! Reference source not found.**, the table also show the key stakeholder categories for each partnership. Most consultation respondents participated in the following partnerships: Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, Clean Sky 2 Joint Undertaking, European Metrology Programme for Innovation and Research (EMPIR) and in Bio-Based Industries Joint Undertaking. The comparison between the non-campaign and campaign groups of respondents shows that the overall distribution is quite similar. However, there are some differences. For the campaign group almost a half of respondents is/was involved in the Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking, a higher share of campaign respondents is/was participating in Clean Sky 2 Joint Undertaking and in Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking.

When respondents were asked in which **role(s) they participate(d) in a partnership(s)**, over 40% indicated that they act(ed) as partner/member/beneficiary in a partnership. The second largest group of respondents stated that they applied for funding under a partnership. The roles selected by non-campaign and campaign respondents are similar.

Table 4: Partnerships in which consultation respondents participated (N=1035)

Name of the partnership	Number and % of respondents from both groups (n=1035)	Number and % of respondents from a non-campaign group (n=815)	Academic/research institutions	Business associations	Company/business organisations	Company/business organisations	EU citizens	NGOs	Public authority
Fuel Cells and Hydrogen 2 (FCH2) Joint Undertaking	354 (33.33%)	247 (30.31%)	97	9	37	43	41	8	5
Clean Sky 2 Joint Undertaking	195 (18.84%)	145 (17.79%)	57	2	10	27	37	1	7
European Metrology Programme for Innovation and Research (EMPIR)	150 (14.49%)	124 (15.21%)	64	0	13	9	14	2	19
Bio-Based Industries Joint Undertaking	142 (13.72%)	122 (14.97%)	39	8	20	27	14	1	6
Shift2Rail Joint Undertaking	124 (11.98%)	101 (12.40%)	31	7	5	31	14	3	7
Electronic Components and Systems for European Leadership (ECSEL) Joint Undertaking	111 (10.72%)	88 (10.80%)	42	2	7	20	12	0	5
Single European Sky Air Traffic Management Research (SESAR) Joint Undertaking	66 (6.38%)	46 (5.64%)	10	3	3	20	3	2	3
5G (5G PPP)	53 (5.12%)	47 (5.77%)	20	1	6	14	5	0	1
Eurostars-2 (supporting research-performing small and medium-sized enterprises)	44 (4.25%)	40 (4.91%)	17	0	6	1	7	0	6
Innovative Medicines Initiative 2 (IMI2) Joint Undertaking	37 (3.57%)	35 (4.29%)	18	2	3	3	2	4	3
Partnership for Research and Innovation in the Mediterranean Area (PRIMA)	28 (2.71%)	26 (3.19%)	15	0	3	1	2	0	2
European and Developing Countries Clinical Trials Partnership	25 (2.42%)	24 (2.94%)	12	0	1	2	3	3	2
Ambient Assisted Living (AAL 2)	22 (2.13%)	21 (2.58%)	11	2	1	1	3	0	3
European High-Performance Computing Joint Undertaking (EuroHPC)	22 (2.13%)	18 (2.21%)	6	0	2	3	5	0	2

For the remaining of the consultation, respondents could provide their views on each/several of the candidate initiatives. The majority of respondents (31.4%) provided their views on the Clean Hydrogen candidate partnership. More than 45% of respondents from the campaigns selected this partnership. Around 15% provided their views for European Metrology, Clean Aviation and Circular Bio-based Europe. The share of respondents in the campaign group that chose to provide views on the Clean Aviation candidate partnership is of 20%. The smallest number of respondents provided opinions on the candidate initiative ‘EU-Africa research partnership on health security to tackle infectious diseases – Global Health’.

Table 5: Candidate Institutionalised Partnerships for which consultation respondents provide responses (N=1613)

Name of the candidate Institutionalised European partnership	Number and % of respondents from both groups (n=1613)	Number and % of respondents from a non-campaign group (n=1341)
Clean Hydrogen	506 (31.37%)	382 (28.49%)
European Metrology	265 (16.43%)	225 (16.78%)
Clean Aviation	246 (15.25%)	191 (14.24%)
Circular bio-based Europe	242 (15%)	215 (16.03%)
Transforming Europe’s rail system	184 (11.41%)	151 (11.26%)
Key Digital Technologies	182 (11.28%)	162 (12.08%)
Innovative SMEs	111 (6.88%)	110 (8.20%)
Innovative Health Initiative	110 (6.82%)	108 (8.05%)
Smart Networks and Services	109 (6.76%)	107 (7.98%)
Safe and Automated Road Transport	108 (6.70%)	102 (7.61%)
Integrated Air Traffic Management	93 (5.77%)	66 (4.92%)
EU-Africa research partnership on health security to tackle infectious diseases – Global Health	49 (3.04%)	47 (3.50%)

1.2.2. Characteristics of future candidate European Partnerships

Respondents were asked to assess what areas, objectives, aspects need to be in the **focus of the future European Partnerships** under Horizon Europe and to what extent. According to Figure 6, a great number of respondents consider that a significant contribution by the future European Partnerships is ‘fully needed’ to achieve climate-related goals, to the development and effective deployment of technology and to EU global competitiveness in specific sectors/domains. Overall, respondents’ views reflect that many aspects require attention of the Partnerships. The least attention should be paid to responding towards priorities of national, regional R&D strategies, including smart specialisation strategies, according to respondents.

Overall, only minor differences can be found between the main stakeholder categories. Academic/research institutions value the responsiveness towards EU policy objectives and focus on development and effective deployment of technology a little less than other respondents. Business associations, however, find that the future European Partnerships under Horizon Europe should focus a little bit more on the development and effective deployment of

technology than other respondents. Furthermore, business associations, large companies as well as SMEs value the role of the future European Partnerships for significant contributions to EU global competitiveness in specific sectors domains a little higher than other respondents. Finally, both NGOs and Public authorities put a little more emphasis on the role of the future European Partnerships for significant contributions to achieving the UN SDGs. The views of citizens (249, or 18.3%) do not reflect significant differences with other types of respondents. However, respondents that are/were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7 assign a higher importance of the future European Partnerships to be more responsive towards EU policy objectives and to make a significant contribution to achieving the UN’s Sustainable Development Goals.

A qualitative analysis of the “other” answers highlights the importance of collaboration and integration of relevant stakeholders to tackle main societal challenges and to contribute to policy goals against which fragmentation of funding and research efforts across Europe should be avoided. Additionally, several respondents suggested that faster development and testing of technologies, acceleration of industrial innovation projects, science transfer and market uptake are needed. Next to that, many respondents provided answers related to the hydrogen and the energy transition, which corresponds to the high number of respondents that provided answers to the candidate initiative on this topic.

Figure 6: To what extent do you think that the future European Partnerships under Horizon Europe need to (N=1363) (non-campaign replies) For all candidate initiatives

1.2.3. Main advantages and disadvantages of Institutionalised European Partnerships

An open question asked to outline the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe (1551 respondents). The advantages mentioned focus on the development of technology, overall collaboration between industry and research institutions, and the long-term commitment. Disadvantages mentioned are mainly administrative burdens. An overview is provided below.

Advantages mentioned: Long term commitment, stability, and visibility in financial, legal, and strategic terms; Participation of wide range of relevant stakeholders in an ecosystem (large/small business, academics, researchers, experts, etc.); Complementarity with other (policy) initiatives at all levels EU, national, regional; Efficient and effective coordination and management; High leverage of (public) funds; Some innovative field require high levels of international coordination/standardisation (at EU/global level); Ability to scale up technology (in terms of TRL) through collaboration; Networking between members; Direct communication with EU and national authorities

Disadvantages mentioned: Slow processes; System complexity; Continuous openness to new players should be better supported as new participants often bring in new ideas/technologies that are important for innovation; Lower funding percentage compared to regular Horizon Europe projects; Cash contributions; Administrative burdens; Potential for IPR constraints.

1.2.4. Relevance of EU level to address problems in Partnerships' areas

Respondents were asked to rate the **relevance of research and innovation efforts at EU level efforts to address specific problems in the area of partnerships**. Research and innovation related problems were rated as most relevant across all candidate initiatives, followed by structural and resources problems and problems in the uptake of innovations. Overall, all three areas were deemed (very) relevant across the partnerships, as more than 80% of respondents found these challenges (very) relevant. Only minor differences were found between stakeholder categories. Research and innovation problems were found slightly more relevant by academic/research institutions, yet slight less relevant by large companies and SMEs. Structural and resource problems were indicated as slightly more relevant by NGOs, but slightly less by academic/research institutions. While both NGOs and public authorities find slightly more relevant to address problems in uptake of innovation than other respondents. The views of citizens are not differing significantly. Respondents that are/were directly involved in a current/preceding partnership find, however, the need to address problems related to the uptake of innovations slightly more relevant than other respondents.

Figure 9: To what extent do you think this is relevant for research and innovation efforts at EU level to address the following problems in relation to the candidate partnership in question? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.5. Horizon Europe mode of intervention to address problems

Respondents were asked to indicate how these challenges could be addressed through **Horizon Europe intervention**. Just over 50% of all respondents indicated that institutionalised partnerships were the best fitting intervention, with relatively strong differences between stakeholder categories. The use of Institutionalised Partnership was indicated more by business associations and large companies, but less by academic/research institutions and SMEs. While academic/research institutions valued traditional calls more often, this was not the case for business associations, large companies and public authorities. Public authorities indicated a co-programmed intervention more often than other respondents. Citizens indicated slightly less often that institutionalised partnerships were the best fitting intervention. Respondents that are/were directly involved in a current/preceding partnership, selected the institutionalised partnership intervention in far higher numbers (nearly 70%).

Figure 10: In your view, how should the specific challenges described above be addressed through Horizon Europe intervention? (non-campaign replies) For all candidate initiatives

When asked to reflect on their answers, respondents that pointed to the need for using institutionalised partnership mentioned the long-term commitment of collaboration, a common and ambitious R&I strategy as well as the overall collaboration between industry and research institutions. Others shared positive experiences with other modes of interventions:

- Traditional calls, because of their flexibility and integration of a wide range of actors, as long as the evaluation panels do not deviate from the policy focus. This was mentioned by 94 participants, including companies (25), academics (26) and EU citizens (25).
- Co-funded partnership, as a mechanism to ensure that all participants take the effort seriously, while allowing business partnerships to develop. This approach was deemed suitable based on previous experiences with ERANETs. This was raised by 84 participants, 36 of them academic respondents, 18 companies and 16 EU citizens.
- Co-programmed partnerships, to tackle the need to promote and engage more intensively with the private sector. This was mentioned by 97 participants, most of them companies (34), followed by academics (22), business associations (15) and EU citizens (11).

1.2.6. Relevance of a set of elements and activities to ensure that the proposed European Partnership would meet its objectives

Setting joint long-term agendas

Respondents were asked how relevant it is for the proposed European Partnerships to meet their objectives to have a strong involvement of specific stakeholder groups in setting joint long-term agenda. All respondents see stakeholders from industry as the most relevant,

followed by academia and governments. The involvement of foundations and NGOs as well as other societal stakeholders were, however, still found to be (very) relevant by more than 50% of the respondents. Most respondents indicated the stakeholder group they belong to themselves or that represent them as relevant to involve.

Figure 11: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives - Setting joint long-term agenda with strong involvement of: (non-campaign replies) For all candidate initiatives

Pooling and leveraging resources through coordination, alignment and integration with stakeholders

Respondents were asked how relevant it is for the proposed European Partnership to meet its objectives to pool and leverage resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with specific groups of stakeholders. Respondents see stakeholders from industry as the most relevant, followed by academia and governments (Member States and Associated Countries). The involvement of foundations and NGOs as well as other societal stakeholders are also still found to be (very) relevant for more than 50% of the respondents. Similarly as described for the question on setting joint long-term agendas, most stakeholder categories valued their own involvement higher than other respondents – although also here differences between stakeholder categories were minor.

Figure 12: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Pooling and leveraging resources (financial, infrastructure, in-kind expertise, etc.) through coordination, alignment and integration with: (non-campaign replies) For all candidate initiatives

Composition of the partnerships

Regarding the composition of the partnership most respondents indicated that for the proposed European Partnership to meet its objectives the composition of partners needs to be flexible over time and that a broad range of partners, including across disciplines and sectors, should be involved (see Figure 13). When comparing stakeholder groups only minor differences were found. Academic/research institutions and public authorities found the involvement of a broad range of partners and flexibility in the composition of partners over time slightly more relevant than other respondents, while large companies found both less relevant. SMEs mainly found the flexibility in the composition of partners over time less relevant than other respondents, while no significant differences were found regarding the involvement of a broad range of partners. Citizens provided a similar response to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, indicated a slightly lower relevance of the involvement of a broad range of partners and flexibility in the composition of partners over time.

Figure 13: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Partnership composition (non-campaign replies) Aggregation of responses of all candidate initiatives

Implementation of activities

Most respondents indicated that implementing activities like a joint R&I programme, collaborative R&I projects, deployment and piloting activities, providing input to regulatory aspects and the co-creation of solutions with end-users are all (very) relevant for the partnerships to be able to meet its objectives. Minor differences were found between the main stakeholder categories, the differences found were in line with their profile. As such, academic/research institutions found joint R&I programme & collaborative R&I projects slightly more relevant and deployment and piloting activities, input to regulatory aspects and co-creation with end-users slightly less relevant than other respondents. For SMEs an opposite pattern is shown. Large companies, however, also found collaborative R&I projects slightly more relevant than other respondents, as well as input to regulatory aspects. The views of citizens are similar to non-citizens. Respondents that are/were directly involved in a current/preceding partnership, when compared to respondents not involved in a current/preceding partnership, show a slightly higher relevance across all activities.

Figure 14: In your view, how relevant are the following elements and activities to ensure that the proposed European Partnership would meet its objectives – Implementing the following activities (non-campaign replies) For all candidate initiatives

1.2.7. Relevance of setting up a legal structure (funding body) for the candidate European Partnerships to achieve improvements

Respondents were asked to reflect on the relevance of setting up a legal structure (funding body) for achieving a set of improvements, as shown in the Figure below. In general, 70%-80% of respondents find a legal structure (very) relevant for these activities. It was found most relevant for implementing activities in a more effective way and least relevant for ensuring a better link to practitioners on the ground, however differences are small.

Figure 15: In your view, how relevant is to set up a specific legal structure (funding body) for the candidate European Partnership to achieve the following? (non-campaign replies) Aggregation of responses of all candidate initiatives

When comparing stakeholder categories there are only minor differences. Academic/research institutions indicated a slightly lower relevance for transparency, better links to regulators as well as obtaining the buy-in and long-term commitment of other partners. SMEs also indicated a lower relevance regarding obtaining the buy-in and long-term commitment of other partners. Large companies showed a slightly higher relevance for implementing activities effectively, ensure better links to regulators, obtaining the buy-in and long-term commitment of other partners, synergies with other EU/MS programmes and collaboration with other EU partnerships. NGOs find it slightly more relevant to implement activities faster for sudden market or policy needs. Public authorities, however, find it slightly less relevant to facilitate collaboration with other European Partnerships than other respondents. The views of citizens show a slightly lower relevance for a legal structure in relation to implementing activities in an effective way. Respondents that are/were directly involved in a current/preceding partnership indicated a higher relevance across all elements presented.

1.2.8. Scope and coverage of the candidate European Partnerships based on their inception impact assessments

Consulted on the scope and coverage for the partnerships, based on their inception impact assessments, the large majority feels like the scope and coverage initially proposed in the inception impact assessments is correct. However, about 11% to 15% of the respondents indicated the scope and coverage to be too narrow. About 11%-17% of respondents answered “Don’t know”. Overall, differences between the main stakeholder categories were found to be minor. Academic/research institutions indicated slightly more often that the research area was “too narrow” than other respondents. SMEs on the other hand indicated slightly more often that the research area and the geographical coverage were “too broad”. NGOs and public authorities, however, found the geographical coverage slightly more often “too narrow”. Large companies found the range of activities slightly more often “too broad” and the sectoral focus slightly more often “too narrow” when compared to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership more often indicated that the candidate institutionalised European Partnership have the “right scope & coverage”.

Figure 16: What is your view on the scope and coverage proposed for this candidate institutionalised European Partnership, based on its inception impact assessment? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.2.9. Scope for rationalisation and alignment of candidate European Partnerships with other initiatives

When asked whether it would be possible to rationalise a specific candidate European Institutionalised Partnership and its activities, and/or to better link with other comparable initiatives, nearly two thirds of respondents answered “Yes” (1000, or 62%), while over one third answered “No” (609, or 39%). Nearly no differences were found between stakeholder categories, only large companies and SMEs indicated slightly more often “Yes” in comparison to other respondents. The views of citizens are the same as for other respondents. Respondents that are/were directly involved in a current/preceding partnership, indicated “No” more often, the balance is about 50/50 between “Yes” and “No” for this group.

1.2.10. Relevance of European Partnerships to deliver targeted scientific, economic/technological and societal impacts

Finally, respondents were asked to rate the relevance of partnership specific impacts in three main areas: Societal; Economic/technological; and Scientific impacts. All three areas were deemed (very) relevant across the candidate partnerships. Scientific impact was indicated as the most relevant impact, more than 90% of respondents indicated that this as (very) relevant. Only minor difference between stakeholder groups were found. Academic/research institutions found scientific impacts slightly more relevant, while large companies found economic and technological impacts slightly more relevant than other respondents. NGOs found societal impact slightly more relevant, while SMEs found this slightly less important. Citizens did not a significantly different view when compared to other respondents. Respondents that are/were directly involved in a current/preceding partnership find all impacts slightly more relevant than other respondents.

Figure 17: In your view, how relevant is it for the candidate European Institutionalised Partnership to deliver on the following impacts? (non-campaign replies) Aggregation of responses of all candidate initiatives

1.3. Stakeholder consultation results for the Clean Hydrogen Initiative

1.3.1. *Feedback to the inception impact assessment on candidate initiatives for Institutionalised Partnerships*

Following the publication of the inception impact assessment, a feedback phase of 3 weeks allowed any citizen to provide input on the proposed initiatives on the “Have your say” web portal. In total 350 feedbacks were collected for all initiatives.

For the initiative “Clean Hydrogen” 38 individual feedbacks were collected, mainly from company/business organisations (15) and business associations (12).⁶ Among the elements mentioned were:

- This new partnership should build on the progress made by the FCH 2 JU (“Fuel Cells and Hydrogen 2 Joint Undertaking) during the last decade which has demonstrated effectiveness especially for the coordination of the programme and alignment of priorities between the various stakeholders;
- 14 respondents clearly wrote that the institutionalised European Partnership based on Article 187 TFEU (option 2) offers the most effective way of delivering the objectives of the initiative;
- Uptake of the production and consumption of renewable or decarbonised hydrogen is slowed down by a lack of political commitment, perfectible market design, important costs and varying technology readiness levels (TRL);
- Coordination between economic actors and between sectors, such as mobility, energy, heating and industry, is key and can be better achieved within an iPPP;
- Openness to EU-13 MS is essential and needs to be improved;
- Key components: gas infrastructure & underground storage (to transport and store renewable hydrogen) to meet demand from the power, industry, land and marine transportation and heating sectors;
- The overall leverage achieved in the FCH JU (i.e. level of private investment compared with EU finding) to date stands at 1.96, compared to 1.09 during the FP7 programme. This leverage effect is forecasted to rise to 3.0.

Beyond the cooperation expected from an R&D programme, the creation of an Institutionalised Partnership has led to many additional coordination efforts: MoUs with 90+ regions and cities; various hydrogen mobility initiatives across MS; better synergies with other European programmes (CEF, ETS Innovation Fund, etc.); co-funding with national and regional programmes; and more.

Whilst this Institutionalised Partnership would support and enable cooperation between the actors of the wider Hydrogen Value Chain, it needs to be complemented: first, by sector-specific Hydrogen activities; secondly, by activities focusing specifically on aspects of industrial cross-sectoral nature; third, by Hydrogen-related infrastructural investment; as well as, fourth, the regulatory environment, which would provide access to the CO₂-lean electricity (needed to operate the Hydrogen Value Chain) at costs, which do not undermine the global economic feasibility of this value chain.

1.3.2. Structured consultation of the Member States on European partnerships

A structured consultation of Member States through the Shadow Strategic Configuration of the Programme Committee Horizon Europe in May/June 2019 provided early input into the preparatory work for the candidate initiatives (in line with the Article 4a of the Specific Programme of Horizon Europe). This resulted in 44 possible candidates for European Partnerships identified as part of the first draft Orientations Document towards the Strategic Plan for Horizon Europe (2021-2024), taking into account the areas for possible institutionalised partnerships defined in the Regulation.

The feedback provided by 30 countries (all Member States, Iceland and Norway) has been analysed and summarised in a report, with critical issues being discussed at the Shadow Strategic Programme Committee meetings.

For the initiative “Clean Hydrogen” the following overall feedback was received from Member States: *“countries support the proposed partnership, and its objectives. Key issues raised by delegations and that may need further discussion include the need to ensure systems aspects and sectoral coupling for the use of hydrogen technologies, and agreeing on the areas for applications”*.

“Overall there is a good agreement on the use of a partnership approach in addressing energy transition through clean hydrogen technologies (64% consider it very and 11% somewhat relevant). There is broad agreement (71%) that the partnership is more effective in achieving the objectives and delivering clear impacts for the EU and its citizens, but to a lesser degree (43%) that it would contribute to improving the coherence and synergies within the EU R&I landscape.”

Delegations identified further of aspects that could be reinforced in the proposal a partnership *“that would increase its relevance for national priorities, e.g.⁷ ensure synergies with other related partnerships (e.g. Clean Hydrogen)”*... Other comments were related to *“avoiding duplications with other Partnerships (notably on Integrated Air Traffic Management and Hydrogen), and clarifying objectives”*.

Section on “clean hydrogen”

“Overall the results of the consultation confirm the relevance of the proposed European Partnership on Clean Hydrogen, with 82% considering it very or somewhat relevant for their research organisations, including universities, 79% for their national policies and priorities, and 72% of respondents found the proposed partnership to be relevant for their industry”.

Figure 1: Relevance of the European Partnership for Clean Hydrogen in the national context

⁷ Comments on scope and content have to be assessed in the context of the overall priority setting to ensure coherence.

On the question of existing national/regional R&I strategies, plans and/ or programmes in support of the proposed Partnership for Clean Hydrogen, 25 countries report to have relevant elements in place. National economic sectoral strategies and/or plans with a strong emphasis on research and innovation (54%, AT, CZ, DE, DK, EE, FR, HR, IT, LUC, LV, NL, SE, SI, SK, NO) and regional R&I and/or smart specialisation strategies (54%, AT, BE, DE, DK, EL, ES, FR, HR, NL, PL, PT, SE, SI, SK, UK) were identified most frequently, followed by national R&I strategies or plans (50%, DE, DK, EE, FR, HR, LV, NL, PT, RO, SE, SI, SK, IS, NO), dedicated R&I funding programmes or instruments (46%, AT, DE, DK, ES, FR, HR, NL, RO, SE, SI, SK, UK, NO). Eight countries (FR, HR, HU, IE, NL, PT, SE, SK) reported other policies/ programmes, such as national /state support plans and cross-sectoral roadmaps.

Delegations identified a number of aspects that could be reinforced in the proposal for this partnership that would increase its relevance for their national priorities. Several delegations emphasise the need to ensure systems aspects and sectoral coupling, notably by developing demonstrators for the use of hydrogen technologies in energy, transport and industry. In a similar manner, several countries indicated specific areas of interest for applications, e.g.: all types of road transport (not just heavy-duty transport), the maritime sector, small-scale hydrogen usage, transportation and storage. Various comments also pointed out the need to ensure alignment with national activities, as well as the complementarity and synergies with other related partnerships/initiatives/programmes to cover the entire Hydrogen value chain. Other individual comments suggest to, e.g.:

- Include infrastructure for heavy-duty and FCEVs
- Ensure R&I activities among the whole value chain
- Extend the scope to the development of fuels with high energy density
- Include hydrogen sensor as an important field of application
- Assess the role of Carbon Capture & Storage as a means of achieving the scale required both for volume and cost
- Include technologies for distribution of hydrogen through pipelines
- Focus on near-zero carbon hydrogen production pathways

Many countries (64%) are undecided concerning their interest to participate in an initiative. At this stage 9 countries (BE, DE, EE, ES, FR, IT, MT, RO, NO) expressed interest to join as a partner, and only one country (CY) indicated that there is no national interest to participate. Governmental research organisations (61%), research infrastructures (50%), and planned

national R&I programmes (50%) are most frequently identified as potential partners or contributors.

While many are undecided concerning their participation, all countries show interest in having access to results produced in the context of the partnership.

Feedback on objectives and impacts

Overall there is a good agreement on the use of a partnership approach in addressing energy transition through clean hydrogen technologies (64% consider it to be very relevant and 11% see it as somewhat relevant). There is broad agreement (71%) that the partnership is more effective in achieving the objectives and delivering clear impacts for the EU and its citizens, but to a lesser degree (43%) that it would contribute to improving the coherence and synergies within the EU R&I landscape.

Countries indicate strong agreement with the proposed short, medium and long term objectives, as well as with the expected scientific, economic and societal impacts at the European level (79%). Slightly fewer MS (75%) consider the impacts to be relevant in the national context. Three-quarters (75%) of the countries find the envisaged duration of the proposed partnership to be adequate, although some delegations point out that there is insufficient information to assess the appropriate timeframe. In additional comments, delegations reiterated some of the points made regarding elements to be reinforced, notably sector coupling and inclusion of all transport modes. Additional individual comments highlighted the need to allow technology-neutral solutions (in this context, one delegation suggested a merger with 2ZERO), to consider international initiatives in the field, and to include H₂ production from renewables through water electrolysis, water thermochemical splitting and biomass gasification, and photochemical water splitting.

Views on partners, contributions and implementation

Around two-thirds (64%) of the countries agree on the type and composition of partners, whilst 18% remain neutral and 7% disagree. In additional comments, several countries' delegates emphasised the need to ensure stronger involvement of Member States and local authorities in the partnership to guarantee alignment with national activities. Other comments stressed the need to ensure a more balanced participation from other countries, stakeholders and actors compared to the current set-up of the Fuel Cells and Hydrogen Joint Undertaking, notably by ensuring increased involvement of smaller suppliers for the hydrogen industry.

At this stage, the majority of the countries' respondents (79%) indicated that they would need more information on the contributions and level of commitments expected from partners.

More than half (61%) of the countries needed more information to assess the proposed mode of implementation based on Article 187 TFEU, while 8 countries are in favour and 3 against. In the additional comments, three countries favour explicitly implementation through a co-programmed model, and two countries stress the need for comprehensive assessments as to whether a co-programmed or institutionalised model is more effective. One country supported implementation through competitive calls in Horizon Work Programmes.”

1.4. Targeted consultation of stakeholders

In addition to the consultation exercises coordinated by EC services, the external study thematic teams performed targeted consultations with businesses, research organisations and other partners on different aspects of potential European Partnerships.

1.4.1. Approach to the targeted consultation

Few actors have experience with different types of initiatives (usually actors involved in H2 funding have only experience with either standard EU programme calls or with the FCH JU, but not with a co-programmed or co-funded scheme). Therefore, it was difficult to ask them for their opinions on the “best option.” With each topic, the main objective for the interviewers was to collect data that would allow for distinguishing between the options to determine which was best, given their characteristics. The co-funded initiative and Article 185 were quickly deemed out of scope, so that interviewers focused on the baseline, the co-programmed and the existing Article 187 options. It was obvious that all interviewees – even the five actors that were not currently involved in FCH JU calls – favoured an IP (some strongly, others with some nuances). These actors favoured an IP due to the increasing scope of applications in the hydrogen field, and the growing need for coordination and a strong community within the sector.

The partnership in Clean Hydrogen would require engagement not only with stakeholders from across the European Hydrogen community, but also from across new non-H2 sectors, in order to fulfil low carbon objectives. An outline of stakeholders targeted for interviews is presented in the table below; it was drafted by taking into account current trends in the field of H2.

1.4.2. Overview of respondents to the targeted consultation

The table below shows that targeted interviewees were well-distributed across categories, with strong representation from Research and Academia, End-use industry and Manufacturing industry. The subsequent figure illustrates how interviewees were primarily based in areas with strong national hydrogen programmes, including Germany, France, the Netherlands and Spain. Efforts were also made to reach out to relevant Eastern and Southern European countries in order to collect a diversity of perspectives.

Table 1 – Number of interviews per stakeholder category

Stakeholder category	Number	Share (%)
Manufacturing industry	7	15%
Association	4	8%
Grid operator	2	4%
Research & academia	13	27%
Civil society	1	2%

Stakeholder category	Number	Share (%)
National associations	3	6%
End use industry	8	17%
MS and EU Commission	6	13%
Industry (utilities)	2	4%
Local authority representatives	1	2%
Integrators / developers	1	2%
TOTAL	48	100%

1.4.3. Key results/messages from the targeted consultation

Scope of the initiative

- Focus on Clean Hydrogen complete chains: the focus of a partnership should be on hydrogen generation, delivery (transport, distribution and storage) and end-use, covering all relevant sectors and applications.

The partnership should only support the scale-up of clean hydrogen applications, i.e., technologies that produce and use hydrogen from low carbon sources (like renewable or other low carbon electricity, or SMR combined with CCUS).
- Technology neutral: the initiative should not focus on specific technologies or applications but should remain open to all potential developments.
- Sector coupling & infrastructure development: the coupling of renewable electricity production and hydrogen generation is seen as a key technology route for propagating clean hydrogen and a key enabler for the deployment of renewables. The FCH JU has been instrumental in reaching out to renewables companies and other potential end-users to increase their interest in hydrogen applications – many new organisations across several different sectors have incorporated hydrogen into their long-term strategies (e.g., power companies, gas distributors) largely due to FCH JU outreach.

The development of infrastructure (gas pipelines and refuelling stations) is considered as a key enabler to deploy clean hydrogen at scale. There is also a need to define the form in which hydrogen will be transported (e.g., compressed, liquid). The initiative should provide support to ensure that infrastructure investments are encouraged, even if they must be realised by the industry with private capitals (connections to receive support from the CEF could help).
- Continuous improvement: through further RD&I, there is need to spur further cost decreases, quality improvements and performance enhancements of all technologies, applications and stacks. There is still room for improvement in all sectors and for all applications, even for applications that are ready-to-market. The JU has demonstrated its ability to develop technologies to expected maturity levels in the direction of market uptake, and has proven its ability to strengthen the hydrogen community and encourage shared practices and knowledge at all TRLs.

- Coordination with other sectors and/or initiatives: the initiative will have to ensure coordination with other initiatives in concerned sectors. The need for strong coordination can be better handled with an IP than with any other option. For example, the gas sector will play a key role in hydrogen's rollout, but there is no existing initiative on decarbonising gas grids, so it will be important for the partnership to involve gas sector stakeholders. This is true for several "end use" sectors.

Collaboration between all sectors relevant to clean hydrogen is of paramount importance, as they complement one another while sharing a broad low-carbon vision and the scientific knowledge and skills necessary to adapt existing technologies appropriately.

Policy and regulatory vacuum

- No market conditions: there is a need for market uptake of several technologies considered ready-to-market (including FC buses, FC forklifts, stationary FCs, microgrids, and certain types of electrolyzers). Further improvement of these applications could be prompted by industry deploying technologies at scale. However, necessary market conditions are missing, jeopardising their deployment. The risk of losing the benefits of past years' RD&I efforts is high, if market uptake does not increase within the EU. While it is no longer the role of RD&I to support market uptake, an IP could provide vital support to foster requisite market conditions (both regulatory and policy).

- Absence of regulation: as H2 applications are maturing within all sectors, the need for regulation is increasing. An optimal first space for addressing regulatory requirements is within the RD&I sphere, as it contains actors with the required knowledge (both industry- and research-based actors) and with views on market constraints (industry actors).

In addition, the dominance of a strong hydrogen community at an EU level would make discourse with other global regions more efficient, as the EU could address international norms and standards with a single voice. A strong community would also support the leading position of EU organisations.

- Missing vision: the lack of a cohesive European hydrogen policy is a big issue. Without a long-term vision on hydrogen rollout, stakeholders are confident there will be insufficient commitment to launch new markets and secure investors.

The JU is the most appropriate framework for proposing and implementing a clear vision on sequential next steps for hydrogen uptake: design, develop, improve, integrate and deploy at scale.

Coordination and cooperation

- There is a need for strong coordination between Research and Industry as the former has knowledge/views on fundamental R&D and emerging technologies and the latter is well-versed in market needs and trends. A community that gathers both types of stakeholders is very important and should be strengthened to ensure complementarity along the entire hydrogen value chain. An IP is the most appropriate option for maintaining and reinforcing the strong, existing European hydrogen community.
- A community addressing all related topics: community coordination is essential in order to help establish a clear agenda that identifies priorities and necessary activities in the clean hydrogen space. This community can most effectively be hosted by an IP.

Involving authorities

- MS involvement: for some stakeholders, sharing best practices will bring MS on board “naturally.” But for others, outreach is still needed in order to increase interest. At the MS-level, the European HyENet initiative has made a very good start in engaging with authorities, as it plans to support exchanges on market trends, to present best practices and leverage downstream development.
- Local authorities involvement: local authorities have an important role to play in enabling clean hydrogen uptake; they are involved with public awareness, permitting, coordination, setting low carbon roadmaps, creating early market conditions, responding to local needs, and bringing funds for projects. Therefore, depending on the specific needs of a project or an application that can be deployed at the local level, their involvement in a partnership could become essential. An IP would be the most appropriate structure to support knowledge-sharing and to liaise with important local actors and develop local hydrogen communities.

Awareness

- Specific vs general: awareness must be properly fostered. Outreach on hydrogen should correctly explain the technical, economic and environmental characteristics of different hydrogen applications.
- Extensive diffusion: established best practices should be encouraged and propagated in all concerned industries.

EU positioning

- Relevant for all applications: the supply chain for clean hydrogen applications is dispersed across sectors and industries; knowledge management encourages collaboration and linkages between potential partners. An appropriate IP provides such effective knowledge management.
Targeted areas for R&D should be determined based on identified needs (among end-users) rather than on established practices (what EU industry is doing). Therefore, even in segments and with technologies where other regions are gaining prominence (e.g., Asia, which leads in FCEV rollout), it is still important to support R&I, given the need for building blocks and considering that assemblers play a role within hydrogen value chains as well.
- Vital for SMEs: FCH JU plays a **vital role in supporting SMEs**. Within national governments, there is a feeling that larger industrial players dominate the conversations on the strategies for hydrogen, and that they steer national funding towards their own organisations. But the FCH JU provides a forum for SMEs to substantially contribute to/engage in strategic discussions, and there is more of a sense that funding is allocated to projects which really merit it.

Market uptake

- Demonstration: there is a consensus among stakeholders that hydrogen applications are entering a phase of real demonstration. Many demonstration projects will be managed at the MS level, with important industry leverage. EU level intervention and monitoring will remain important to ensure that coordination addresses cross-border projects and linkages between different actors throughout Europe.
- Industrialisation: There is still a strong need for R&D efforts in developing hydrogen applications; whereas in the past R&D mainly focused on scientific and technological development, there is now a much stronger need for research focused on production processes and commercial deployment. The industrialisation phase of hydrogen

applications will depend on market uptake. R&D funds can go into validating the applications (as the phase of industrialisation remains outside the R&D sphere). Complementarity could be developed with the Innovation Fund (from ETS) to support this phase of industrialisation. This is where an IP, with good knowledge management, could also provide some support (in preparing calls or screening projects).

- Financing: where competitiveness of end use applications is market volume-dependent, an effective market launch will be possible only with policy incentives. Decision makers should therefore seize all opportunities of an H2 economy by setting up adequate support frameworks. An IP, with deep expertise, can provide support in developing and deploying incentives.

Strategic Research & Innovation Agenda

- As H2 is versatile and can be integrated into various sectors using many different applications, it is vital to prepare a coherent SRIA, which is able to draw from current efforts and results to develop a longer term vision. The SRIA should ideally ensure that there is a proper articulation between the long-term CO2 strategy objectives AND the applications where we can expect cost decreases. Coupling the SRIA and H2 strategy is essential and could be best managed by an IP.
- Balance between low and high TRLs. It is important to address all levels of technological readiness in the RD&I agenda. Most stakeholders agree that over the next ten years, RD&I should be concentrated on technologies at high, nearly market-ready levels and at low, potentially innovative levels. EU contributions should decrease when addressing higher TRL projects, to ensure higher private contributions for demonstration projects. An IP is the most appropriate structure through which to prompt increasing industry leverage.

Openness

- The initiative should work at a global level, or at least be connected to all relevant counterparts to ensure compliance with international standards, to secure the role of EU industry in different hydrogen spaces, and to make sure that regulatory issues are addressed properly. An IP is probably the most appropriate initiative to foster collaboration at international levels, given its expertise and knowledge management.
- Open calls: there is a consensus among the interviewees that calls for funding should remain open, but it is considered important (strategically and financially) to ensure that there are incentives that keep members of the IP community consistently interested in its efforts.

Long term commitment

- Public / private collaboration on long term is key. An IP is considered the most appropriate structure for ensuring follow-up and engaging both public and private players in the long run.
Fundamental R&D could be facilitated and reinforced by providing structural funding to centres and academia in a more programmatic ways, avoiding the need to regularly submit new project proposals. With clear and strict monitoring, programming could ensure a longer-term and coherent vision of the R&D agenda, and alleviate the process of launching new calls.
- Long-term application selection: for some applications (e.g. in the maritime or aviation sectors), there is need to test out different technologies and alternatives in order to be

able to later see which is the most appropriate for deployment at scale. It takes years to test applications and requires long-term commitments to carbon emission reduction at large scales.

1.5. Open Public Consultation

1.5.1. Characteristics of respondents

There are 382 respondents who have answered (part of) the consultation for the Clean Hydrogen Partnership. Of these respondents, 76 (19.90%) were citizens. The largest group of respondents were businesses and academic and research institutions both with 123 respondents (32.20%). There were 21 respondents from business associations (5.50%). The other respondents were representatives of public authorities (13, 3.4%), non-governmental organisations (8, 2.09%) or other (17, 4.45%). Over 3/4s of respondents, namely 293 (76.70%), have been involved in the on-going research and innovation framework programme, of which 245 respondents (83.62%) were directly involved in a partnership under Horizon 2020 or its predecessor Framework Programme 7.

1.5.2. Results on general questions

Relevance of efforts of the candidate European Partnership to address problems

At the beginning of the consultation, the respondents of this partnership were asked to indicate their views on the needs of the future European Partnerships under Horizon Europe. All 382 respondents answered these questions. Overall, the respondents indicated that many of the options presented were very relevant. The option where most respondents indicated this, was making a significant contribution to the EU efforts to achieve climate-related goals (320, 83.77%), which is not surprising considering the focus of this partnership. The option where the least amount of respondents indicated that improvements were very relevant, being more responsive towards priorities in national and/or regional R&I strategies (114, 29.84%). No statistical differences were found between the views of citizens and other respondents.

Figure 1: Views of the respondents in regard to the needs of future European Partnerships under Horizon Europe (N=382)

The respondents also had the option to indicate other needs. The results show that respondents have indicated needs around international policy and industrial competition as well as the development of technology for clean hydrogen fuels and cells.

Main advantages and disadvantages of participation in the Institutionalised European Partnership

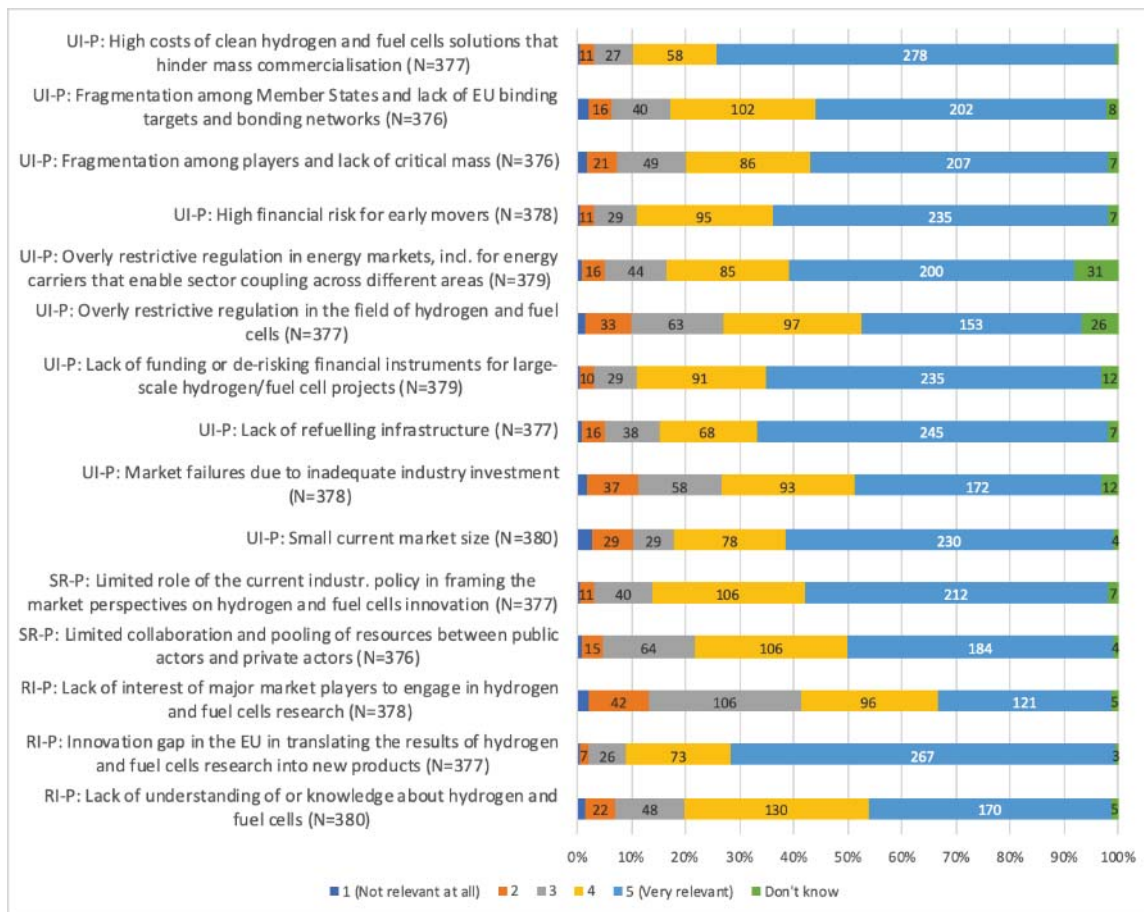

The respondents were asked what they perceived to be the main advantages and disadvantages of participation in an Institutionalised European Partnership (as a partner) under Horizon Europe. This analysis showed the respondents mentioned long term commitment and collaboration in relation to advantages and efficient management and higher visibility in relation to disadvantages.

1.5.3. Results on candidate European Partnership specific questions

Relevance of research and innovation efforts at the EU level to address problems

In the consultation, respondents were asked to provide their view on the relevance of research and innovation efforts at EU level to address the following problems in relation to hydrogen and fuel cells, specifically on three types of problems: problems in uptake of hydrogen and fuel cells innovations (UI-P), structural and resource problems (SR-P) and research and innovations problems (RI-P). In Figure 2 the responses to these answers are presented.

Figure 2: Views of respondents on relevance of research and innovation efforts at the EU level to address problems in relation to hydrogen and fuel cells

With regard to the uptake in innovation problems, 278 respondents have indicated that it is very relevant for research and innovation efforts at EU level to address the problem of high costs of clean hydrogen and fuel cells solutions that hinder mass commercialisation until serial production is achieved, factoring-in economies of scale (73.74%). Of the uptake in innovation problems, market failures due to inadequate industry investment has the least amount of very relevant answers (45.50%), while most respondents still have indicated that they view this issue as very relevant.

There were only two structural and resource problems that the respondents were asked to reflect on. Of these the limited role of current industrial policy in framing the market perspectives related to hydrogen and fuel cells innovation, received more 5 (very relevant) answers, namely 60.53% of responses.

The research and innovation problem that most people have indicated as very relevant is the innovation gap in the EU in translating the results of hydrogen and fuel cells research into new products, with 267 respondents choosing this answer (70.82%). The problem that was least often indicated as very relevant, is also a research and innovation problem, namely: lack of interest of major market players to engage in hydrogen and fuel cells research (121, 32.01%).

No statistical differences were found between the views of citizens and other respondents. Respondents that are/were involved in a current/preceding partnership (Horizon 2020 or Framework Programme 7) found all uptake in innovation problems more relevant than other respondents.

Horizon Europe interventions to address problems

After providing their views on the relevance of problems, respondents were asked to indicate how these challenges could be addressed through Horizon Europe intervention. As shown in Figure 3, just over 65% of respondents indicated that institutionalised partnerships were the best fitting intervention.

No statistical differences were found between the views of citizens and other respondents.

Figure 3: Assessment of Horizon Europe intervention

The respondents were asked to briefly explain their answers to the question above. People who stated that an institutionalised partnerships was the best fitting answer, mentioned long term, research and innovation and private funding.

Relevance of involvement of actors in setting joint long-term agenda

Respondents were asked how relevant the involvement of actors is in setting a joint long-term agenda to ensure that the proposed European Partnership would meet its objectives (see Figure 4). The highest amount of respondents indicated that the involvement of Industry is very relevant (323 respondents or 86.13%). A large part of respondents also indicated that the involvement of Academia (215, 58.58%) and Member States and Associated Countries (201, 53.46%) is very relevant. With regard to Foundations and NGO's, respondents indicate that their involvement is seen as less relevant, with only 70 (19.23%) respondents indicating that their involvement is very relevant and a 135 respondents (37.09%) indicating that their involvement is a 3 on the relevance scale.

No statistical differences were found between the views of citizens and other respondents.

Figure 4: Views of respondents on relevance of actors in setting joint long-term agenda

Relevance of elements and activities in pooling and leveraging resources

With respect to the relevance of actors in pooling and leveraging resources, such as financial, infrastructure, in-kind expertise etc.), to meet Partnership objectives, the patterns are similar. First, 301 respondents (80.05%) indicated that industry was very relevant, which is much

larger than for any of the other stakeholders. 205 (54.14%) respondents felt that Member States and Associated Countries were very relevant and 188 (51.37%) of respondents indicated that Academia were very relevant. Foundations and other stakeholders were deemed less relevant, since only 68 (18.68%) and 89 (24.31%) respondents respectively indicated that these stakeholders were very relevant. No respondents indicated that any of the categories was not relevant at all.

No statistical differences were found between the views of citizens and other respondents.

Figure 5: Views of respondents on relevance of actors for pooling and leveraging resources

Relevance of elements and activities for the partnership composition

Respondents were asked about the relevance of the Partnership composition, such as flexibility in the composition of partners over time and involvement of a broad range of partners (including across disciplines and sectors), to reach Partnership objectives. As it is visible in Figure 6, ensuring involvement of a broad range of partners has more 'very relevant' answers (143, 38.96%) than the flexibility in the composition of partners (112, 30.60%). Almost 17% (16.94%) of respondents has indicated that flexibility in composition is worth a 2 on the relevancy scale, for ensuring involvement of a broad range of partners, this is the case for 47 respondents (12.81).

No statistical differences were found between the views of citizens and other respondents. Respondents that are/were directly involved in a current/preceding partnership found flexibility in the composition of partners less relevant.

Figure 6: Views of respondents on relevance of partnership composition elements

Relevance of implementation of activities

Respondents were asked to provide opinions on the relevance of implementation of several activities for meeting objectives of the Clean Hydrogen Partnership. Among activities were

listed – joint R&D programme, collaborative R&D projects, deployment and piloting activities, input to regulatory aspects and co-creation of solutions with end-users. Out of 375 respondents, 292 (77.86%) indicated that deployment and piloting activities are very relevant to ensure that the Partnership would meet its objectives. For all the other options, the majority (over 60%) of all respondents have indicated that these are very relevant. See Figure 7. No statistical differences were found between the views of citizens and other respondents. Respondents that are/were directly involved in a current/preceding partnership found most activities slightly more relevant than other respondents.

Figure 7: Views of respondents on relevance of implementation of the following activities

Relevance of a legal structure (funding body) to achieve specific objectives

Respondents were also asked to assess the relevance of a specific legal structure (funding body) for the candidate European Partnership to achieve several activities. According to Figure 8, respondents indicated that it was very relevant to set up a specific legal structure for the partnership to achieve a more effective implementation of activities (235, 62.67%) and to increase financial leverage (229, 60.90%). Although ‘to ensure better links to practitioners on the ground’ and ‘to obtain more buy-in and long term commitment from other partners, have received the least 5 (very relevant) answers (106 and 123 respectively), they have received the most 4 answers. Which could indicate that they are still seen as important, just slightly less important than the other options.

No statistical differences were found between the views of citizens and other respondents. Respondents that are/were directly involved in a current/preceding partnership found a legal structure slightly more relevant for most objectives.

Figure 8: Views of respondents on relevance of a specific legal structure

Scope and coverage of the candidate European Partnership

Respondents were asked to assess the scope and coverage of the proposed Clean Hydrogen Partnership, based on its inception impact assessment. The clear majority of the respondents have indicated that the partnership has the right scope and coverage across all areas. The respondents have been the most positive with regard to technologies covered, where 261 respondents (70.54%) have indicated the partnership has the right scope and coverage. The respondents who have indicated that the scope and coverage are not right, have indicated that it was too narrow more often than they viewed it as too broad.

No statistical differences were found between the views of citizens and other respondents.

Figure 9: Views of respondents on the scope and coverage proposed for the Clean Hydrogen partnership

Aside from this multiple choice question, the respondents were also asked to provide any comment that they may have on the proposed scope and coverage for this candidate Institutionalised Partnership. This analysis showed the respondents used this question to talk about low TRL levels, flagship projects and the production and distribution of hydrogen technology.

Alignment of the European Partnership with other initiatives

The respondents were also asked if they thought it would be possible to rationalise the candidate European Institutionalised Partnership and its activities, and/or to better link it with

other comparable initiatives. 165 respondents (48.53%) have indicated that they think this is the case.

No statistical differences were found between views of citizens and other respondents.

The respondents who answered affirmative, where asked which other comparable initiatives it could be linked with. The results show that respondents think the initiative could be linked with other comparable initiatives related to hydrogen, renewable energy and the application of hydrogen as well as clean aviation and rail systems.

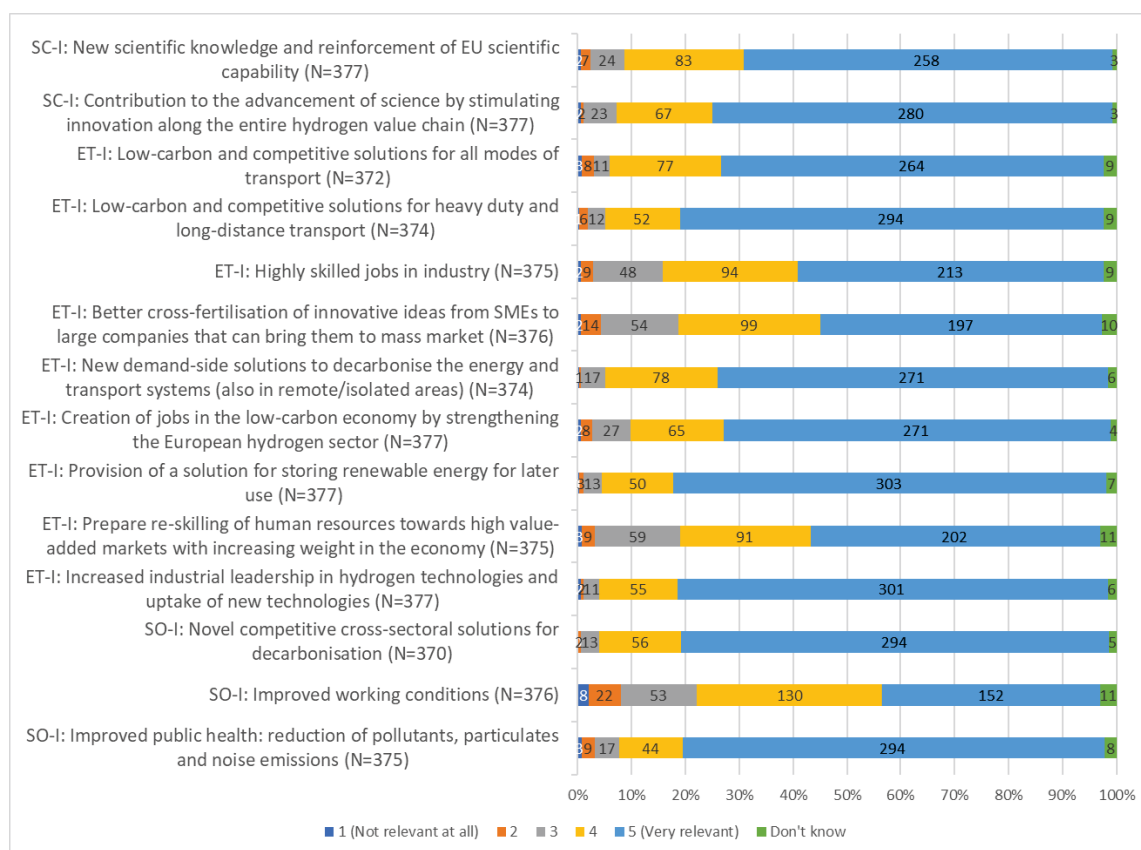

For the respondents who answered negatively on the previous question, The results show that respondents mention key success factors, other initiatives, other partnerships and the energy system and energy transport.

Relevance of the Candidate European Partnership to deliver impacts

Based on Figure10, among presented societal impacts, only the category “improved working conditions” has a relatively low number of respondents that consider that the Partnership would be ‘very relevant’ for this impact category. In other categories, around 80% of respondents consider that the Partnership would be ‘very relevant’ to deliver on those impacts. Similarly, among listed economic/technological impacts, around 80% of respondents suggest that the Partnership would have a significant effect on/be ‘very relevant’ for increasing industrial leadership in hydrogen technologies and uptake of new technologies, for provision of a solution for storing renewable energy for later use, and for provision of low-carbon and competitive solutions for heavy duty and long-distance transport. In contrast, the least number of respondents, namely 197 out of 376 (52.39%), expect a significant impact of the candidate Partnership on better cross-fertilisation of innovative ideas from SMEs to large companies. Around 70% of respondents indicated that the Partnership will have a significant impact on all listed categories in the area of science.

No statistical differences were found between the views of citizens and other respondents. Respondents that are/were involved in a current/preceding partnership found most economic/technological and scientific impacts more relevant than other respondents.

Figure10: Views of respondents on the relevance of the candidate European Institutionalised Partnership to various impacts

1.5.4. Summary of campaigns results

Five campaigns were identified among respondents that provided answers for the current candidate Partnership:

1. campaign #1 includes 57 respondents
2. campaign #2 includes 25 respondents
3. campaign #7 includes 18 respondents
4. campaign #9 includes 13 respondents
5. campaign #11 includes 9 respondents

Only the overview for campaign #1 is presented.

Table 1: Overview of responses of the first campaign (campaign #1) (N=57)

Question category	Summary of responses
Research and innovation problems	The answer category “Innovation gap in the EU in translating the results of hydrogen and fuel cells research into new products” was assessed as ‘very relevant’ by all respondents. Other categories have mixed and lower scores, on average.
Structural and resource problems	With exception of three respondents, all respondents gave a high score (5 ‘very relevant’) for both answer categories.
Problems in uptake of digital innovations	Across all answer categories, most respondents selected the option 5 ‘very relevant’.

Preferred Horizon Europe intervention	<p>Institutionalised Partnership was selected by all respondents.</p> <p>When respondents were asked to explain their choice, all of them used the following quote: <i>"IPPP with its specific governance and 7 years budget enables the sector to define and implement a common ambitious R&I strategy. IPPP unique in coordinating innovation effort beyond industry and research with regions, end-users, members states, other industrial sectors, other EU programmes. IPPP superior in leveraging EU funding with private contributions and other funding sources"</i>.</p>
Relevance of actors for setting join long-term agenda	A higher number of respondents consider that the involvement of industry and academia is 'very relevant'. Foundation and NGOs received the lowest score (3.21), on average.
Relevance of actors for pooling and leveraging resources	A higher number of respondents consider that the involvement of industry and academia is 'very relevant'. Foundation and NGOs received the lowest score (3.30), on average.
Partnership composition	Both categories received a relatively low score (between 2 and 3), on average.
Implementation of activities	Across all categories, the majority of respondents indicated that listed activities are 'very relevant'.
Relevance of the legal structure	On average, across all categories, respondents indicated that the legal structure would be 'very relevant'. The exceptions include the following categories "ensure better links to practitioners on the ground", "obtain more buy-in and long-term commitment from other partners" and "ensure harmonisation of standards and approaches". In these categories, on average, respondents gave a score of 4 'relevant'.
Scope and coverage of the candidate Partnership	<p>Across all answer categories, most respondents consider that the elements are of right scope and coverage.</p> <p>Respondents were offered an opportunity to provide comments on the proposed scope and coverage of the Institutionalised Partnership. Most of them included the following quote: <i>"Inception impact assessment says little. PPP infosheet for member states included excellent description with three pillars: 1. Near-zero carbon hydrogen production + 2. Technologies distribution and storage + 3. Demand side technologies for (a) power and/or heat in industry, (b) and building and the (c) In the transport sector with focus on heavy duty road freight, rail, and water-borne. Programme to include adapted instruments to support low TRL, flagship projects and EU supply chain"</i>.</p>
Rationalisation of the candidate Partnership and linking to other initiatives	<p>Out of 57 respondents, 53 (92.98%) consider that it would not be possible to rationalise the candidate Partnership and its activities, and/or to better link it with other comparable initiatives.</p> <p>Respondents were asked to explain their answer. Regardless of the answer option, all of them inserted a following quote: <i>"We believe that Hydrogen should have its proper partnership and there is no value in merging it with another partnership. It would increase complexity and lose the focus which is key success factor of an IPPP. Nevertheless we value focussed cooperation with a number of partnerships in particular Clean Aviation, Transforming EU Rail, Waterborne, Built Environment, Clean and Low Carbon Steel, Clean and Circular Industry, Batteries and 2Zero"</i>.</p>

Societal impact	Almost all respondents consider that the Partnership would be 'very relevant' to deliver on the following results: "improved public health, reduction of pollutants etc." and "novel competitive cross-solutions for decarbonisation". The other suggested impact is considered 'relevant', on average, by respondents.
Economic/technological impact	Across all listed categories, majority of respondents indicated that impacts are 'very relevant'.
Scientific impact	Across all listed categories, majority of respondents indicated that impacts are 'very relevant'.

1. PRACTICAL IMPLICATIONS OF THE INITIATIVE

The proposed Clean Hydrogen Partnership focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU. It will produce quantifiable contributions towards the achievement of climate targets in 2030 and for climate neutrality by 2050. The following stakeholder groups are affected by the proposed initiative, as explained below:

- Academia and the scientific community play a pivotal role in strengthening and integrating scientific capacity to accelerate the development and improvement of advanced clean hydrogen applications ready for market, across energy, transport, building and industrial end-uses;
- The private sector, by having a central role in the proposed Clean Hydrogen Partnership, will benefit from the long-term vision and financial certainty required for its businesses and industries to grow and to strengthen the competitiveness of the EU clean hydrogen value chain (notably SMEs);
- Civil society as a whole is mainly affected by the climate change issue. The proposed Clean Hydrogen Partnership provides the right framework to increase public awareness, acceptance and trust of Hydrogen solutions and services. Having civil society on board is a prerequisite for the clean energy transition to happen, in particular for the development of a highly transformative sector such as Hydrogen;
- Finally, in an increasingly globalized and interlinked world, governments are required to enhance their role in the fight against climate change. New evidence on this issue should be incorporated in every level of policy-making and in every sector. Governments are responsible for the development, implementation and enforcement of environmental clean energy and climate change regulation that addresses current and future problems. The proposed Clean Hydrogen Partnership will be instrumental in providing a relevant scientific and technology evidence base.

For the preferred option

<i>I. Overview of Benefits (total for all provisions) – Preferred Option</i>		
<i>Description</i>	<i>Estimation (quantitative or qualitative)</i>	<i>Comments</i>
<i>Direct benefits</i>		
More competitive hydrogen industry	Hydrogen applications are more competitive, efficient and reliable.	
Clean Hydrogen scale up	EU validates its ability to scale-up clean economical hydrogen end-use applications in heavy-duty transport and energy-intensive	

	industries – maintaining global competitiveness.	
Economic growth particularly for SMEs	EU growth in hydrogen economy, especially for SMEs.	When the clean hydrogen value chain develops, it will be possible to monitor the number of SMEs operating in the sector.
Indirect benefits		
Decarbonisation of heavy industry	The EU's maritime, aviation, rail and heavy-duty transport sectors, as well as their gas grid, can progressively decarbonize so the EU can meet its climate targets.	
Reduction in pollution and CO2 emissions	Outdoor pollution can progressively decrease while reducing carbon emissions at the same time.	
Incorporation of larger shares of renewable energy in European electricity grids.	The European electricity grid can accommodate larger shares of renewable energy, thanks to flexibility services provided by power to gas installations.	

(1) Estimates are relative to the baseline for the preferred option as a whole (i.e. the impact of individual actions/obligations of the preferred option are aggregated together); (2) Please indicate which stakeholder group is the main recipient of the benefit in the comment section; (3) For reductions in regulatory costs, please describe details as to how the saving arises (e.g. reductions in compliance costs, administrative costs, regulatory charges, enforcement costs, etc.; see section 6 of the attached guidance).

II. Overview of direct and indirect costs – Preferred option							
		Citizens/Consumers		Businesses		Administrations	
		One-off	Recurrent	One-off	Recurrent	One-off	Recurrent
Management/ Administrative costs	Direct costs						Other cost €2.1 million ⁸ .
	Indirect costs						
Personnel costs	Direct costs						€ 2.9 million corresponding to 27 full time equivalent staff ⁹
	Indirect costs						
Coordination costs (or transaction costs)							

⁸ These are the costs of running the FCH JU from the 2018 Annual report.

⁹ These are the costs of running the FCH JU from the 2018 Annual report.

Budget expenditure/ investment costs							
---	--	--	--	--	--	--	--

(1) Estimates to be provided with respect to the baseline; (2) costs are provided for each identifiable action/obligation of the preferred option otherwise for all retained options when no preferred option is specified; (3) If relevant and available, please present information on costs according to the standard typology of costs (compliance costs, regulatory charges, hassle costs, administrative costs, enforcement costs, indirect costs; see section 6 of the attached guidance).

REFIT Cost savings table

Not applicable for the proposed Clean Hydrogen Partnership. The initiative will benefit from the existing organisation/structure (e.g. the Programme Office) already in place for the FCH 2 JU. There are no additional regulatory costs associated, and no specific simplification measures apply in this case.

Annex 4 Analytical Methods

The methodology for each impact assessment is based on the Commission Better Regulation Guidelines¹⁰ to evaluate and compare options with regards to their **efficiency, effectiveness and coherence**. This is complemented by integrating the **conditions and selection criteria for European Partnerships**, as well as requirements for setting up Institutionalised Partnerships.¹¹

1. OVERVIEW OF THE METHODOLOGIES EMPLOYED

In terms of **methods and evidence used**, the set of impact assessments for all candidate Institutionalised European Partnerships draw on an external study covering all initiatives in parallel to ensure a high level of coherence and comparability of analysis¹².

All impact assessments mobilised a mix of qualitative and quantitative data collection and analysis methods. These methods range from desk research and interviews to the analysis of the responses to the Open Consultation, stakeholder analysis and composition/portfolio analysis, bibliometric/patent analysis and social network analysis, and a cost-effectiveness analysis.

The first step in the impact assessment studies consisted in the definition of the context and the problems that the candidate partnerships are expected to solve in the medium term or long run. The main data source in this respect was desk research. This includes grey and academic literature to identify the main challenges in the scientific and technologic fields and in the economic sectors relevant for the candidate partnerships, as well as the review of official documentations on the policy context for each initiative.

In the assessment of the problems to address, the lessons to be learned from past and ongoing partnerships were taken into account, especially from relevant midterm or ex-post evaluations.

The description of the context of the candidate institutionalised European Partnerships required a good understanding of the corresponding research and innovation systems and their outputs already measured. Data on past and ongoing Horizon 2020 projects, including the ones implemented through Partnerships, served as basis for descriptive statistic of the numbers of projects and their respective levels of funding, the type of organisations participating (e.g. universities, RTOs, large enterprises, SMEs, public administrations, NGOs, etc.) and how the funding was distributed across them. Special attention was given to analysing the participating countries (and groups of countries, such as EU, Associated Countries, EU13 or EU15) and industrial sectors, where relevant. The sectoral analysis required enriching the eCORDA data received from the European Commission services with sector information extracted from ORBIS, using the NACE codification up to level 2. These data enabled the identification of the main and, where possible, emerging actors in the relevant systems, i.e. the organisations, countries and sectors that would need to be involved (further) in a new initiative.

¹⁰ European Commission (2017), Better Regulation Guidelines (SWD (2017) 350)

¹¹ A pivotal element of the present analysis is the so-called two-step ‘necessity test’ for European Partnerships, used to establish: step 1) the need for a partnership approach in the first place, followed by step 2) a justification for the form of Institutionalised Partnership. The necessity test is described in Annex 6. This impact assessment focuses on the second step of the test.

¹² Technopolis Group (2020), Impact Assessment Study for Institutionalised European Partnerships under Horizon Europe.

A Social Network Analysis was performed by the contractors using the same data. It consisted in mapping the collaboration between the participants in the projects funded under the ongoing R&I partnerships. This analysis revealed which actors – broken down per type of stakeholders or per industrial sector – collaborate the most often together, and those that are therefore the most central to the relevant research and innovation systems.

The data provided finally served a bibliometric analysis run by the contractor aimed at measuring the outputs (patents and scientific publications) of the currently EU-funded research and innovation projects. A complementary analysis of the Scopus data enabled to determine the position and excellence of the European Union on the international scene, and identify who its main competitors are, and whether the European research and innovation is leading, following or lagging behind.

A cost modelling exercise was performed in order to feed into the efficiency assessments of the partnership options.

The conclusions drawn from the data analysis were confronted to the views of experts and stakeholders collected via three means:

- The comments to the inception impact assessments of the individual candidate institutionalised European Partnerships;
- The open public consultation organised by the European Commission from September to November 2019;
- The interviews (up to 50) conducted by each impact assessment study team conducted between August 2019 and January 2020 (policymakers, business including SMEs and business associations, research institutes and universities, and civil organisations, among others).

The views of stakeholders (and experts) were particularly important for determining the basic functionalities (see further below) that the future partnerships need to demonstrate to achieve their objectives as well as their most anticipated scientific, economic and technological, and societal impacts. The interviews allowed more flexibility to ask the respondents to reflect about the different types of European Partnerships. Furthermore, as a method for targeted consultation, it was used to get insights from the actors that both the Study Teams and the European Commission were deemed the most relevant. For the comparative assessment of impacts, the external contractors confronted the outcomes of the different stakeholder consultation exercises to each other with a view of increasing the validity of their conclusions, in line with the principles of triangulation.

Annex 2 includes also the main outcomes of the stakeholder consultation exercises.

2. METHOD FOR ASSESSING THE EFFECTIVENESS, EFFICIENCY AND COHERENCE OF EACH OPTION - THE USE OF FUNCTIONALITIES

Given the focus of the impact assessment on comparing different forms of implementation, the Better Regulation framework has been adapted to introduce “**key functionalities needed**” – so as to link the intended objectives of the candidate European Partnerships and what would be crucial to achieve them *in terms of implementation*. The identification of “key functionalities needed” for each initiative as an additional step in the impact assessment is based on the distinguishing factors between the different options (see Section 2.2.1 in the main body of the impact assessment). In practical terms, each option is assessed on the basis

of the degree to which it would allow for the key needed functionalities to be covered, as regards e.g. the type and composition of actors that can be involved ('openness'), the range of activities that can be performed (including additionality and level of integration), the level of directionality and integration of R&I strategies; the possibilities offered for coherence and synergies with other components of Horizon Europe, including other Partnerships (internal coherence), and the coherence with the wider policy environments, including with the relevant regulatory and standardisation framework (external coherence). This approach guides the identification of discarded options. It also allows for a structured comparison of the options as regards their effectiveness, efficiency and coherence, and also against a set of other key selection criteria for European Partnerships (openness, transparency, directionality)¹³.

Figure 3 Overview of key functionalities of each form of implementation of European Partnerships

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
Type and composition of actors (including openness and roles)				
<u>Partners:</u> N.A., no common set of actors that engage in planning and implementation <u>Priority setting:</u> open to all, part of Horizon Europe Strategic planning <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation, MS in comitology <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules	<u>Partners:</u> core of national funding bodies or governmental research organisations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> limited, according to national rules of partner countries	<u>Partners:</u> National funding bodies or governmental research organisation <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations	<u>Partners:</u> Suitable for all types: private and/or public partners, foundations <u>Priority setting:</u> Driven by partners, open stakeholder consultation <u>Participation in R&I activities:</u> fully open in line with standard Horizon Europe rules, but possible derogations
Type and range of activities (including additionality and level of integration)				
<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions <u>Additionality:</u> no additional activities and investments outside the funded projects <u>Limitations:</u> No systemic approach beyond individual actions	<u>Activities:</u> Horizon Europe standard actions that allow broad range of individual actions, support to market, regulatory or policy/societal uptake <u>Additionality:</u> Activities/investment s of partners, National funding <u>Limitations:</u> Limited systemic approach beyond individual actions.	<u>Activities:</u> Broad, according to rules/programmes of participating States, State-aid rules, support to regulatory or policy/ societal uptake <u>Additionality:</u> National funding <u>Limitations:</u> Scale and scope depend on the participating programmes, often smaller in scale	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach <u>Additionality:</u> National funding	<u>Activities:</u> Horizon Europe standards that allow broad range of individual actions, support to regulatory or policy/societal uptake, possibility to systemic approach (portfolios of projects, scaling up of results, synergies with other funds). <u>Additionality:</u> Activities/investments of partners/ national funding
Directionality				

¹³ The criterion on the ex-ante demonstration of partners' long term commitment depends on a series of factors that are unknown at this stage, and thus fall outside the scope of the analysis.

Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3.1: Institutionalised Article 185	Option 3.2: Institutionalised Article 187
<p><u>Priority setting:</u> Strategic Plan and annual work programmes, covering max. 4 years.</p> <p><u>Limitations:</u> Fully taking into account existing or to be developed SRIA/roadmap</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution</p> <p>Input to FP annual work programme drafted by partners, finalised by COM (comitology)</p> <p>Objectives and commitments are set in the contractual arrangement.</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by COM</p> <p>Objectives and commitments are set in the Grant Agreement.</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by COM</p> <p>Objectives and commitments are set in the legal base.</p>	<p><u>Priority setting:</u> Strategic R&I agenda/ roadmap agreed between partners and COM, covering usually 7 years, including allocation of Union contribution</p> <p>Annual work programme drafted by partners, approved by COM (veto-right in governance)</p> <p>Objectives and commitments are set in the legal base.</p>
Coherence: internal (Horizon Europe) and external (other Union programmes, national programmes, industrial strategies)				
<p><u>Internal:</u> Between different parts of the Annual Work programme can be ensured by COM</p> <p><u>External:</u> Limited for other Union programmes, no synergies with national/regional programmes and activities</p>	<p><u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM</p> <p><u>External:</u> Limited synergies with other Union programmes and industrial strategies</p> <p>If MS participate, with national/regional programmes and activities</p>	<p><u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM</p> <p><u>External:</u> Synergies with national/regional programmes and activities</p>	<p><u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM</p> <p><u>External:</u> Synergies with national/regional programmes and activities</p>	<p><u>Internal:</u> Coherence among partnerships and with different parts of the Annual Work programme of the FP can be ensured by partners and COM</p> <p><u>External:</u> Synergies with other Union programmes and industrial strategies</p> <p>If MS participate, with national/regional programmes and activities</p>

In line with the Better Regulation Framework, the assessment of the effectiveness, efficiency and coherence of each option is made in comparison to the baseline. Therefore, for each of the above criteria, the performance of using traditional calls under Horizon Europe is first estimated and scored 0 to serve as a reference point. When relevant, this estimation also includes the costs/benefits of discontinuing existing implementation structures. The policy options are then scored compared to the baseline with a + and – system along a two-point scale, to indicate limited (+ or -) or high (++ or --) additional/lower performance compared to the baseline. When a policy option is scored 0, this means that its impact is expected to be roughly equal to the baseline option.

On the basis of the evidence collected, the intervention logic of each initiative and the key functionalities needed, the impact assessments first evaluate the **effectiveness** of the various policy options to deliver on their objectives. To be in line with the Horizon Europe impact

framework, the fulfilment of the specific objectives of the initiative is translated into ‘expected impacts’ - how success would look like -, differentiating between scientific, economic/ technological, and societal (including environmental) impacts. Each impact assessment considers to which extent the different policy options provides the ‘key functionalities needed’ to achieve the intended objectives. The effectiveness assessment does not use a compound score but shows how the options would deliver on the different types of expected impacts. This is done to increase transparency and accuracy in the assessment of options¹⁴.

A similar approach is followed to evaluate the coherence of options with the overarching objectives of the EU’s R&I policy, and distinguishes between **internal** and **external coherence**. Specifically, internal coherence covers the consistency of the activities that could be implemented with the rest of Horizon Europe, including European Partnerships (any type). External coherence refers to the potential for synergies and/or complementarities (including risks of overlaps/gaps) of the initiative with its external environment, including with other programmes under the MFF 2021-27, but also the framework conditions at European, national or regional level (incl. regulatory aspects, standardisation).

To compare the expected costs and benefits of each option (**efficiency**), the thematic impact assessments broadly follow a cost-effectiveness approach¹⁵ to establish to which extent the intended objectives can be achieved for a given cost. A preliminary step in this process is to obtain a measure of the expected costs of the policy options, to be used in the thematic assessments. As the options correspond to different implementation modes, relevant cost categories generally include the costs of setting-up and running an initiative. For instance, set-up costs includes items such as the preparation of a European Partnership proposal and the preparation of an implementation structure. The running costs include the annual work programme preparation costs. Where a Partnership already exists, discontinuation costs are also taken into account¹⁶. The table below provides an overview of the cost categories used in the impact assessment and a qualitative scoring of their intensity when compared to the baseline option (traditional calls). Providing a monetised value for these average static costs would have been misleading, because of the different features and needs of each candidate initiative.¹⁷ Where possible however, Annex 3 to the thematic impact assessments provides additional quantification and details. The cost categories are then used to develop a scorecard analysis and further refine the assessment of options for each of the 12 candidate Institutionalised Partnerships. Specifically, the scores related to the set-up and implementation costs are used in the thematic impact assessments to consider the scale of the expected benefits and thereby allow a simple “value for money” analysis (**cost-effectiveness**)¹⁸. In carrying out the scoring of options, the results of fieldwork, desk research and stakeholder consultation undertaken and taken into account.

¹⁴ In the thematic impact assessments, scores are justified in a detailed manner to avoid arbitrariness and spurious accuracy. A qualitative or even quantitative explanation is provided of why certain scores were given to specific impacts, and why one option scores better or worse than others.

¹⁵ For further details, see Better Regulation Toolbox # 57.

¹⁶ While monetised cost figures are available for existing European Partnerships, they widely differ between each case, thus limiting meaningful comparability. Moreover, they are not readily applicable for new candidate initiatives. Instead, the analysis uses a static, common model of average real costs as a means to show the order of magnitude of efforts and reveal the principal differences between the options.

¹⁷ A complete presentation of the methodology developed to assess costs as well as the sources used is described in the external study supporting this impact assessment (Technopolis Group, 2020).

¹⁸ More details on the methodology can be found in Annex 4.

Figure 4 - Intensity of additional costs compared with Horizon Europe Calls (for Partners, stakeholders, public and EU)

Cost items	Baseline: traditional calls	Option 1: Co-programmed	Option 2 Co-funded	Option 3a - Art. 185	Option 3b - Art. 187
Preparation and set-up costs					
Preparation of a partnership proposal (partners and EC)	0			↑↑	
Set-up of a dedicated implementation structure		0		Existing: ↑ New: ↑↑	Existing: ↑↑ New: ↑↑↑
Preparation of the SRIA / roadmap	0			↑↑	
Ex-ante Impact Assessment for partnership		0			↑↑↑
Preparation of EC proposal and negotiation		0			↑↑↑
Running costs (Annual cycle of implementation)					
Annual Work Programme (AWP) preparation	0			↑	
Call and project implementation	0	0 In case of MS contributions: ↑	↑	↑	↑
Cost to applicants	Comparable, unless there are strong arguments of major differences in oversubscription				
Partners costs not covered by the above	0	↑	0	↑	↑
Additional EC costs (e.g. supervision)	0	↑	↑	↑	↑↑
Winding down costs					
EC			0		↑↑↑
Partners	0	↑	0	↑	↑

Notes: 0: no additional costs, as compared with the baseline; ↑: minor additional costs, as compared with the baseline; ↑↑: medium additional costs, as compared with the baseline; ↑↑↑: higher costs, as compared with the baseline.

3. METHOD FOR IDENTIFYING THE PREFERRED OPTION – THE SCORECARD ANALYSIS

For the **identification of the preferred option**, a scorecard analysis is used to build a hierarchy of the options by individual criterion and overall in order to identify a single preferred policy option or in case of an inconclusive comparison of options, a number of ‘retained’ options or hybrid. This exercise supports the systematic appraisal of alternative options across multiple types of monetary, non-monetary and qualitative dimensions. It also allows for easy visualisation of the pros and cons of each option. Each option is attributed a score of the adjudged performance against each criterion with the three broad appraisal dimensions of effectiveness, efficiency and coherence.

This scorecard approach also relies on a standard cost model developed for the external study supporting the impact assessment, as illustrated in **Error! Reference source not found..** These costs essentially refer to the administrative, operational and coordination costs of the various options. The figure shows how the scoring of costs range from a value of 0, in case an option does not entail any additional costs compared to the baseline (traditional calls), to a score of (-) for options introducing limited additional costs relative to the baseline and a score of (- -) when substantial additional costs are expected in comparison with the baseline. Should the costs of a policy option be lower than those of the baseline, (+) and (+ +) are used.

Figure 5: Matrix on ‘overall costs’ and ‘adjusted cost scoring’

	Baseline: Horizon Europe calls	Option 1: Co-programmed	Option 2: Co-funded	Option 3: Institutionalised
Administrative, operational and coordination costs	0	(-)	(- -)	(- -)
Administrative, operational and coordination costs adjusted per expected co-funding (i.e. cost-efficiency)	0	0	(-)	(-)

Notes: Score 0 = same costs as for the baseline; score (-) = limited additional costs compared to baseline; score (- -) = substantial additional costs compared to baseline.

The **baseline (regular calls)** has the lowest administrative, operational and coordination costs. This is based on two facts: firstly, that Horizon Europe traditional calls will not entail any additional one-off costs to be set up or discontinued at the end, where each of the other policy options will require at least some additional set-up and phasing out costs; and secondly, that Horizon Europe will not require any additional running costs, where each of the other policy options will involve additional efforts by the Commission and partners in the carrying out of necessary additional tasks (e.g. preparing annual work programmes).

A **co-programmed partnership** (Option 1 - CPP) will entail slightly higher overall costs as compared with the baseline. There will be some additional set-up costs linked for example with the creation of a strategic research and innovation agenda (SRIA) and additional running costs linked with the partners role in the creation of the annual work programmes and the Commission’s additional supervisory responsibilities. A CPP will have lower overall costs than each of the other types of European Partnership, as it will function with a smaller governance and implementation structure than will be required for a Co-Funded Partnership or an Institutionalised Partnership and – related to this – its calls will be operated through the existing HEU agencies and RDI infrastructure and systems.

The **Co-Funded Partnership** (Option 2 – CFP) has been **scored (- -)** on overall cost. This reflects the additional set-up costs of this policy option and the substantial additional running costs for partners, and the Commission, of the distributed, multi-agency implementation model.

The **Institutionalised Partnership** (Option 3 - IP) has been **scored (- -)** on overall cost. This reflects the substantial additional set-up costs of this policy option – and in particular the high costs associated with preparing the Commission proposal and negotiating that through to a legal document – and the substantial additional running costs for the Commission associated with the supervision of this dedicated implementation model.

It is considered that while there is a clear gradation in the overall costs of the policy options, the cost differentials are less marked when one takes into account the expected co-financing rates and the total budget available for each of the policy options, assuming a common Union contribution. From this perspective, there are only one or two percentage points that split the most cost-efficient policy options – the baseline (traditional calls) and the Co-Programmed policy options – and the least cost-efficient – the Institutionalised Partnership option. A score of 0 is therefore assigned for **cost-efficiency** to the Co-Programmed option and a score of (-) for the Co-Funded and the Institutionalised Partnership policy options¹⁹.

¹⁹ The baseline (traditional calls) is scored 0, as explained above.

1. Can the Union act? What is the legal basis and competence of the Unions' intended action?
1.1 Which article(s) of the Treaty are used to support the legislative proposal or policy initiative?
<p>This proposal is based on (1) Article 185 TFEU which stipulates that in implementing the multiannual framework programme, the Union may make provision, in agreement with the Member States concerned, for participation in research and development programmes undertaken by several Member States, including participation in the structures created for the execution of those programmes; and (2) Article 187 TFEU according to which the Union may set up joint undertakings or any other structure necessary for the efficient execution of Union research, technological development and demonstration programmes (both Articles are under Title XIX of the TFEU - Research and Technological Development and Space).</p> <p>The proposal aims to implement Article 8 of the Commission proposal for Horizon Europe - the future EU research and innovation (R&I) programme for 2021-2027, according to which, “<i>European Partnerships shall be established for addressing European or global challenges only in cases where they will more effectively achieve objectives of Horizon Europe than the Union alone and when compared to other forms of support of the Framework programme</i>”. The Horizon Europe proposal has received the political agreement of the Council and the European Parliament.</p>
1.2 Is the Union competence represented by this Treaty article exclusive, shared or supporting in nature?
<p>Research is a shared competence between the EU and its Member States according to the TFEU. Article 4 (3) specifies that in the areas of research, technological development and space, the European Union can carry out specific activities, including defining and implementing programmes, without prejudice to the Member States' freedom to act in the same areas.</p> <p><i>Subsidiarity does not apply for policy areas where the Union has exclusive competence as defined in Article 3 TFEU²⁰. It is the specific legal basis which determines whether the proposal falls under the subsidiarity control mechanism. Article 4 TFEU²¹ sets out the areas where competence is shared between the Union and the Member States. Article 6 TFEU²² sets out the areas for which the Unions has competence only to support the actions of the Member States.</i></p>

²⁰ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E003&from=EN>

²¹ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12008E004&from=EN>

²² <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:12008E006:EN:HTML>

2. Subsidiarity Principle: Why should the EU act?

2.1 Does the proposal fulfil the procedural requirements of Protocol No. 2²³:

- Has there been a wide consultation before proposing the act?
- Is there a detailed statement with qualitative and, where possible, quantitative indicators allowing an appraisal of whether the action can best be achieved at Union level?

This proposal and the accompanying impact assessment were supported by a wide consultation of stakeholders, both during the preparation of the Horizon Europe proposal and - later on, all the candidates for European Partnerships. Member States were consulted via the Shadow Strategic configuration of the Horizon Europe Programme Committee. On candidates for institutionalised Partnerships based on Article 185/187 of the TFEU, an Open Public Consultation (OPC) was held between 11 September and 6 November 2019. Over 1 600 replies were received. In addition, targeted consultation activities were undertaken to prepare the present impact assessment. In particular, for each of the candidate partnerships, an external consultant interviewed a representative sample of stakeholders. The need for EU action as well as its added value were covered in those interviews.

The explanatory memorandum and the impact assessment (horizontal part, Section 3) contain a dedicated section on the principle of subsidiarity, as explained in question 2.2 below.

2.2 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the conformity with the principle of subsidiarity?

The impact assessment accompanying the proposal features a horizontal part on relevant common elements to all the candidate partnerships, including the conformity of the proposed initiative with the principle of subsidiarity (Section 3). Moreover, the individual assessments of each candidate partnership include additional details on subsidiarity, touching in particular on the specificities of a candidate partnership that could not be adequately reflected in the horizontal part of the impact assessment. This will also be reflected in the explanatory memorandum.

2.3 Based on the answers to the questions below, can the objectives of the proposed action be achieved sufficiently by the Member States acting alone (necessity for EU action)?

National action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives, to deliver on the EU's strategic policy priorities (including the climate and energy goals set out in the Paris Agreement, and the European Green Deal), and to contribute to tackling global challenges and meeting the

²³ <https://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:12016E/PRO/02&from=EN>

Sustainable Development Goals (SDGs).

(a) Are there significant/appreciable transnational/cross-border aspects to the problems being tackled? Have these been quantified?

The thematic areas covered by the candidate partnerships feature a series of challenges in terms of cross-border/transnational aspects, need to pool resources, need for a critical mass to meet intended policy objectives, need to coordinate different types of actors (e.g. academia, industry, national and regional authorities) across different sectors of the economy and society, which cannot be tackled to the same degree by Member States alone. This is particularly true for the research and innovation (R&I) dimension of the proposed initiative: the importance of a multi-centre and interdisciplinary approach, cross-country data collection and research, and the need to develop and share new knowledge in a timely and coordinated manner to avoid duplication of efforts are key to achieve high quality results and impact. The Interim Evaluation of Horizon 2020 and the impact assessment of Horizon Europe provide extensive qualitative and quantitative evidence on the above points. In addition, Sections 1 and 2 of the individual impact assessments on the candidate partnerships include more detail on the necessity to act at EU-level in specific thematic areas. Finally, it is worth noting that not all Member States have the same capacity or R&I intensity to act on these challenges. As the desired policy objectives can be fully achieved only if the intended benefits are widespread across the Member States, this requires action at the EU-level.

(b) Would national action or the absence of the EU level action conflict with core objectives of the Treaty²⁴ or significantly damage the interests of other Member States?

As per Article 4(3) TFEU, national action does not conflict with core objectives of the Treaty in the area of R&I. The absence of EU level action in this area would however prevent the achievement of core objectives of the Treaty. Indeed, national action alone cannot achieve the scale, speed and scope of support to R&I needed for the EU to meet its long-term Treaty objectives on e.g. competitiveness, to deliver on the EU's strategic policy priorities, and to contribute to tackling global challenges and meet the Sustainable Development Goals (SDGs).

(c) To what extent do Member States have the ability or possibility to enact appropriate measures?

As foreseen by Article 4(3) TFEU, this proposal does not hamper Member States' ability to enact appropriate measures in the field of R&I. However, the scale and complexity of the policy objectives pursued by the present initiative cannot be fully addressed by acting at national level alone.

(d) How does the problem and its causes (e.g. negative externalities, spill-over effects)

²⁴ https://europa.eu/european-union/about-eu/eu-in-brief_en

<p>vary across the national, regional and local levels of the EU?</p>
<p>As described in the horizontal part of the impact assessment accompanying the present proposal, several problems (e.g. on competitiveness, global challenges, demographic change) and their underlying causes affect the EU as a whole rather than individual Member States. Where important differences between Member States are present, these are described in Sections 1 and 2 of the individual impact assessments.</p>
<p>(e) Is the problem widespread across the EU or limited to a few Member States?</p>
<p>The problem of coordinating R&I efforts in the thematic areas covered by the candidate partnerships affects all Member States, albeit to different degrees. However, from a general EU perspective, available evidence shows that the EU as a whole needs to step up efforts and investments in thematic areas that are crucial to tackle present and future policy challenges on several fronts, e.g. ageing population, global technological trends, and climate change to name a few. The way these problems affect the EU and its Member States is described in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual impact assessments.</p>
<p>(f) Are Member States overstretched in achieving the objectives of the planned measure?</p>
<p>As indicated in the horizontal part of the impact assessment and in Sections 1 and 2 of the individual assessments, the sheer scale, speed and scope of the needed support to R&I would overstretch national resources, without guaranteeing the achievement of the intended objectives. Acting at EU-level would achieve greater impact in a more effective and efficient manner.</p>
<p>(g) How do the views/preferred courses of action of national, regional and local authorities differ across the EU?</p>
<p>No specific differences between the views of national, regional and local authorities emerged from the stakeholder consultation.</p>
<p>2.4 Based on the answer to the questions below, can the objectives of the proposed action be better achieved at Union level by reason of scale or effects of that action (EU added value)?</p>
<p>EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. In addition, the proposed initiatives should be seen as complementary and reinforcing national and sub-national initiatives in the same area.</p>

(a) Are there clear benefits from EU level action?

Quantitative and qualitative evidence of the benefits of EU level action are available in the interim evaluation of Horizon 2020 and in the impact assessment of Horizon Europe, among others. An analysis of the emerging challenges in each thematic areas, of the EU's competitive positioning, as well as feedback gathered from different types of stakeholders for the present impact assessment indicate that EU level action remains appropriate also for the present proposal. In addition, the benefits of acting at EU-level have been illustrated by the success and the impact achieved by the predecessors to the proposed initiative.

(b) Are there economies of scale? Can the objectives be met more efficiently at EU level (larger benefits per unit cost)? Will the functioning of the internal market be improved?

EU funded R&I activities, including those covered by the present proposal, produce demonstrable benefits compared to the corresponding national and regional initiatives, due to the scale, speed and scope achievable by acting at the EU level. This is the case both in terms of effectiveness in achieving intended policy objectives, but also in terms of efficiency. Positive impact is also visible in terms of competitiveness: recent data on EU funded R&I activities indicate that EU-funded teams grow 11.8% faster and are around 40% more likely to be granted patents or produce patents applications than non-EU funded teams. Efficiency gains are also visible in terms of dissemination of results to users beyond national borders, including SMEs and citizens. EU funded R&I is more effective in leveraging private investment. Finally, there are clear additionality benefits (i.e. EU R&I funding does not displace or replace national funding), as the EU focuses on projects that are unlikely to be funded at national or regional level. Overall, this is beneficial to the functioning of the internal market in several respects, including human capital reinforcement through mobility and training, the removal of barriers to cross-border activity for economic players including SMEs, easier access to finance and to relevant knowledge and research, and increased competition in the area of R&I.

(c) What are the benefits in replacing different national policies and rules with a more homogenous policy approach?

A homogeneous policy approach in the various thematic areas covered by the present proposal would reduce fragmentation and increase efficiency and effectiveness in meeting the intended policy objectives. Indeed fragmentation, persisting barriers in the internal market and differences in the resources available to Member States are some of the key problems that stand in the way of fully achieving the intended policy objectives and reaching the required critical mass to obtain tangible results. Specific detail on how these issues differ in each thematic area are illustrated in Sections 1 and 2 of the individual impact assessments, so as to reflect the specificities of each case.

(d) Do the benefits of EU-level action outweigh the loss of competence of the Member States and the local and regional authorities (beyond the costs and benefits of acting at

national, regional and local levels)?
The proposed initiative does not lead to a loss of competence of the Member States. In fact, the proposed initiative should be seen as complementary and reinforcing national and sub-national initiatives in the same area. Previous quantitative and qualitative assessments of Horizon Europe and Horizon 2020 have shown that the proposed EU-level action do not displace national ones and tend to concentrate on initiatives that would not have been funded by the Member States themselves, or would not have reached the same scale and ambition without EU-level intervention, due to their complexity and trans-national nature.
(e) Will there be improved legal clarity for those having to implement the legislation?
Yes. The proposed initiatives will be implemented in line with the Horizon Europe single set of rules for participation; this will ensure increased clarity and legal certainty for end beneficiaries, other stakeholders and programme administrators. It will also reduce the administrative burden for beneficiaries, and for the Commission services. In addition, the accessibility and attractiveness of the broader Horizon Europe programme, in particular for applicants with limited resources, would be sustained.
3. Proportionality: How the EU should act
3.1 Does the explanatory memorandum (and any impact assessment) accompanying the Commission's proposal contain an adequate justification regarding the proportionality of the proposal and a statement allowing appraisal of the compliance of the proposal with the principle of proportionality?
The principle of proportionality underpins the entire analysis of the candidate partnerships. Specifically, the analysis included in the accompanying impact assessment is structured along the following logic: 1. Justification of the use of a partnership approach in a given area (including considerations on additionality, directionality, link with strategic priorities) instead of other forms of intervention available under Horizon Europe; 2. If the partnership approach is deemed appropriate, proportionality considerations guide the assessment of which type of partnership intervention (collaborative calls, co-programmed, co-funded or institutionalised partnership) is most effective in achieving the objectives. This will also be reflected in the explanatory memorandum.
3.2 Based on the answers to the questions below and information available from any impact assessment, the explanatory memorandum or other sources, is the proposed action an appropriate way to achieve the intended objectives?
The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments. In addition, the present proposal leaves full freedom to the Member States to

pursue their own actions in the policy areas concerned. This will also be reflected in the explanatory memorandum.

(a) Is the initiative limited to those aspects that Member States cannot achieve satisfactorily on their own, and where the Union can do better?

The proposed initiative only focuses on areas where there is a demonstrable advantage in acting at the EU-level due to the scale, speed and scope of the efforts needed for the EU to meet its long-term Treaty objectives and deliver on its strategic policy priorities and commitments.

(b) Is the form of Union action (choice of instrument) justified, as simple as possible, and coherent with the satisfactory achievement of, and ensuring compliance with the objectives pursued (e.g. choice between regulation, (framework) directive, recommendation, or alternative regulatory methods such as co-legislation, etc.)?

For each of the candidate partnerships, the analysis carried out in the accompanying impact assessment has explored several options for implementation. A comparative assessment of the merits of each option also included an analysis of the simplicity of the intervention, its proportionality and effectiveness in achieving the intended objectives. This is reflected in the fact that a tailored approach has been suggested for each candidate partnership, ranging from looser forms of cooperation to more institutionalised ones, depending on the intended policy objectives, specific challenges, and desired outcome identified in each case.

(c) Does the Union action leave as much scope for national decision as possible while achieving satisfactorily the objectives set? (e.g. is it possible to limit the European action to minimum standards or use a less stringent policy instrument or approach?)

The proposed approach leaves full freedom to the Member States to pursue their own actions in the policy areas covered by the present proposal.

(d) Does the initiative create financial or administrative cost for the Union, national governments, regional or local authorities, economic operators or citizens? Are these costs commensurate with the objective to be achieved?

The proposed initiatives do create financial and administrative costs for the Union, national governments and, depending on the chosen mode of implementation, for regional and local authorities. In addition, economic operators and other stakeholders potentially involved in the candidate partnerships will also incur some costs linked to implementation. The financial cost of the proposed initiative is covered under the Horizon Europe programme. Its exact amount is still subject to political decision. As regards the candidate partnerships and the different modes of implementation (co-programmed, co-funded, institutionalised), the relevant costs and benefits are assessed in the individual impact assessments covering each candidate partnership. The additional administrative costs of implementation via partnerships are

limited, when compared to the administrative costs of implementation through traditional calls. As indicated by comparable experience with previous initiatives and in feedback provided by a variety of stakeholders, these costs are expected to be fully justified by the benefits expected from the proposed initiative. Where available, additional details on costs are provided in Annex 3 of the impact assessment.

(e) While respecting the Union law, have special circumstances applying in individual Member States been taken into account?

Where relevant, differences between Member States in capacity and stage of advancement of R&I in specific thematic areas have been taken into account in the individual impact assessments.

Annex 6 Additional background information

1. BACKGROUND INFORMATION FOR ALL INITIATIVES

1.1. Selection criteria of European Partnerships

Partnerships based on Article 185 and 187 TFEU *shall be implemented only where other parts of the Horizon Europe programme, including other forms of European Partnerships would not achieve the objectives or would not generate the necessary expected impacts, and if justified by a long-term perspective and high degree of integration.* At the core of this impact assessment is therefore the need to demonstrate that the impacts generated through a Partnership approach go beyond what could be achieved with traditional calls under the Framework Programme – the Baseline Option. Secondly, it needs to assess if using the Institutionalised form of a Partnership is justified for addressing the priority.

The necessity test for a European Partnership (as set out in the Horizon Europe regulation) has two levels:

1. **The justification for implementing a priority with a European Partnership** to address Horizon Europe and EU priorities. This is linked to demonstrating that a European Partnership can produce added value beyond what can be achieved through other Framework Programme modalities, notably traditional calls in the work programmes (Option 0 – Baseline).
2. **The justification for the use of the form of Institutionalised Partnership:** Once it has been demonstrated that a partnerships approach is justified, co-programmed and/or co-funded forms are considered for addressing the priorities as they are administratively lighter, more agile and easier to set-up (Options 1 and/or 2). As Institutionalised Partnerships require setting up a legal framework and the creation of a dedicated implementation structure, they have to justify higher set-up efforts by demonstrating that it will deliver the expected impacts in a more effective and efficient way, and that a long-term perspective and high degree of integration is required (Option 3).

The outcomes of the ‘necessity test’ is presented together with the preferred option.

Figure 5 Horizon Europe selection criteria for the European Partnerships

Common selection criteria & principles	Specifications
1. More effective (Union added value) clear impacts for the EU and its citizens	Delivering on global challenges and research and innovation objectives
	Securing EU competitiveness
	Securing sustainability
	Contributing to the strengthening of the European Research and Innovation Area
	Where relevant, contributing to international commitments

Common selection criteria & principles	Specifications
2. Coherence and synergies	Within the EU research and innovation landscape
	Coordination and complementarity with Union, local, regional, national and, where relevant, international initiatives or other partnerships and missions
3. Transparency and openness	Identification of priorities and objectives in terms of expected results and impacts
	Involvement of partners and stakeholders from across the entire value chain, from different sectors, backgrounds and disciplines, including international ones when relevant and not interfering with European competitiveness
	Clear modalities for promoting participation of smes and for disseminating and exploiting results, notably by smes, including through intermediary organisations
4. Additionality and directionality	Common strategic vision of the purpose of the European Partnership
	Approaches to ensure flexibility of implementation and to adjust to changing policy, societal and/or market needs, or scientific advances, to increase policy coherence between regional, national and EU level
	Demonstration of expected qualitative and significant quantitative leverage effects, including a method for the measurement of key performance indicators
	Exit-strategy and measures for phasing-out from the Programme
5. Long-term commitment of all the involved parties	A minimum share of public and/or private investments
	In the case of institutionalised European Partnerships, established in accordance with article 185 or 187 TFEU, the financial and/or in-kind, contributions from partners other than the Union, will at least be equal to 50% and may reach up to 75% of the aggregated European Partnership budgetary commitments

1.2. Overview of potential functions for a common back office among Joint Undertakings

Functions	Current situation	Option of joint back-office	Comments
Organising calls for grant and proposal evaluations	Each JU organises this independently.	A central organisation of evaluation, logistics, contracting evaluators, managing the data of the evaluation results Central database of potential evaluators with domain expertise in thematic areas of partnerships	The evaluations would still need to be supervised by the Scientific staff of the individual Joint Undertakings (consensus meetings of expert evaluators etc)
Human Resources related matters	Each JU has own HR policy and resources Quite some resources spent on recruitment in some JUs	More generic resources and expertise for HR matters More consistency in HR	Ensuring consistency with EC HR policies is already in place

	Some HR facilities are procured from external contractors Some JUs have a Service Level Agreement with COM for HR	policy Shared HR investment for specialised expertise (IP and legal)	
Financial management	Each JU conducts own financial contract management; differences between JUs Each JU is audited separately. Auditing at project level more frequent than in other Horizon 2020 parts and outsourced by JUs thus differences ECA: too many audits on JUs	Financial management by one core team of financial staff Would reduce the number of interfaces for audits and simplifies the auditing of the all JUs Harmonisation of project auditing	Simplifies the harmonisation of financial management across JUs in line with Horizon Europe
Communication (internal and external)	Each JU has a separate communication strategies, teams and resources	A common back-office can support activities such as event organisation, dissemination of results, setting up website communication Can help create a more visible Partnership brand	A considerable share of communication activity is partnership specific (addressing particular target groups, synthesising project results) however there are generic communication activities that can be shared Needs to avoid duplication of efforts
Data management on calls, project portfolios, information on project results	Most JUs but not all use e-Corda for project data Overall IT integration of JUs still difficult	Harmonised data management Reduction of IT systems and support that is procured	This will need to happen regardless of the common back office but will likely be more smooth if managed centrally

2. BACKGROUND INFORMATION FOR THIS SPECIFIC INITIATIVE

2.1. General information on the hydrogen sector

2.1.1. Hydrogen Roadmap.

The scope of hydrogen applications is expanding from its present focus on transport, fuel cells and electrolyzers, and to include the energy sector (power, heating and gas), industry and new transport applications (maritime, aviation, rail, heavy transport).

The objectives of the proposed Clean Hydrogen Partnership are to address hydrogen production (1), hydrogen distribution (2) and storage (3) in order to supply hydrogen (at scale) to the different sectors (4 to 7) and help them to decarbonise.

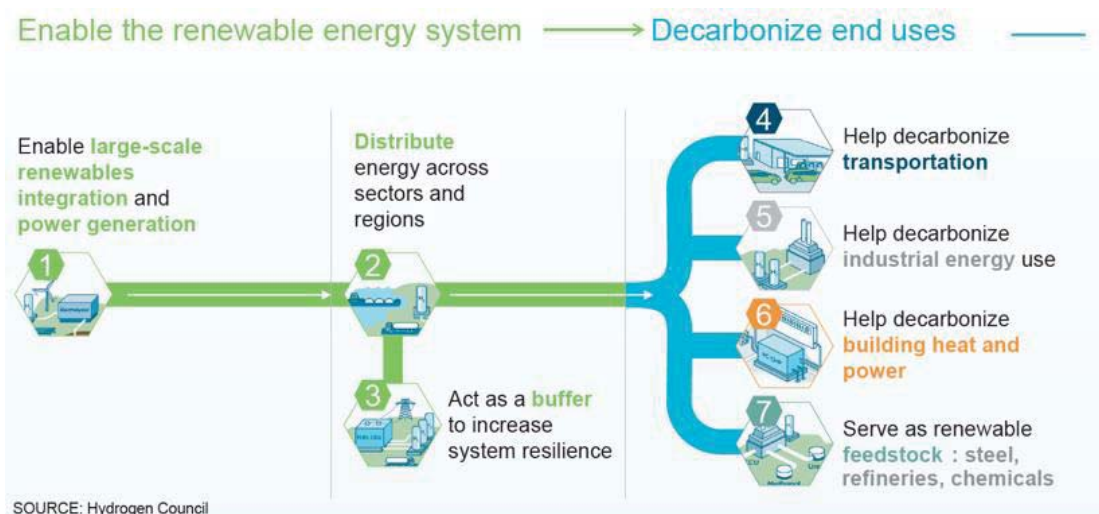

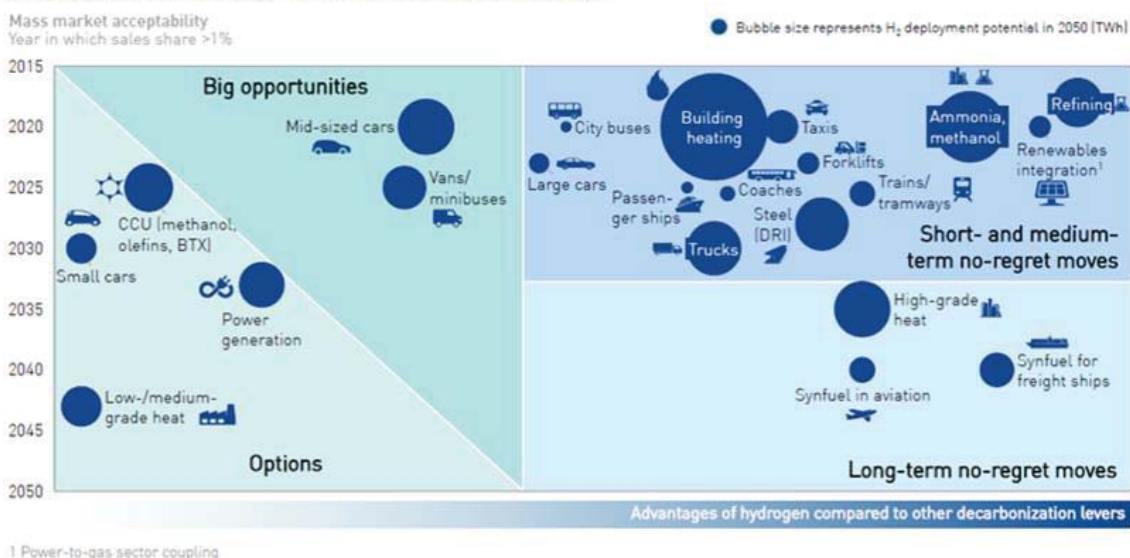

EXHIBIT 28: HYDROGEN OFFERS A NUMBER OF NO-REGRET MOVES, BIG OPPORTUNITIES, AND OPTIONAL INVESTMENT FIELDS FOR PRIORITIZATION

The Figure above highlights the enabling role of hydrogen and the important role it could potentially play in the decarbonisation of a large number of sectors.

2.1.2. Deployment of Hydrogen

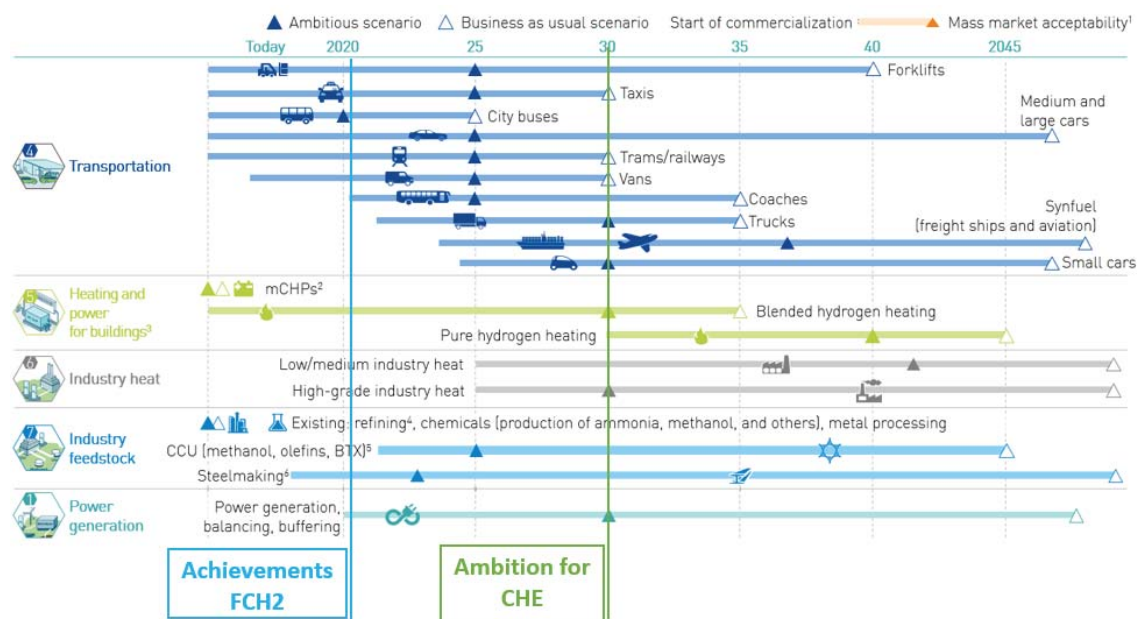

IPHE, the intergovernmental partnership for hydrogen and fuel cells in the economy comprises 20 member countries representing 2/3 of the world's GDP and investing nearly \$1 billion annually in hydrogen and fuel cells. IPHE collects every 6 months information provided by Government officials (Country Reports) on hydrogen deployment.

Today worldwide, there are >14,000 fuel cell electric vehicles (FCEVs), >300 hydrogen refueling stations (HRSs), >1/3 million stationary fuel cells in operation, and 600 MW of electrolyser's installed capacity¹.

Figures for Europe: 1730 FCEVs; 78 fuel cell buses, 15 garbage trucks; 185 HRSs deployed for road transport, 34 Water Electrolysers (PEM, Alkaline, SOEC) 34 deployed within the current FCH 2 JU (incl. 24 at HRSs, 4 at Telecom, 2 for grid autonomy and 4 for grid services) - 9 more planned, excl. HRSs (2 for H₂ storage, 1 for refinery, 4 Power to Gas applications, 2 for other industrial purposes).

Regarding the production of hydrogen, it is important to note that today hydrogen represents 1% of the energy mix and only 1% of this 1% corresponds to green hydrogen (produced from renewable energy sources). It is clear that the EU has to push for the production of clean hydrogen at scale. This activity will be supported under hydrogen production in the proposed clean hydrogen partnership. There will be no deployment of hydrogen and fuel cell applications without developing the hydrogen supply chain.

In conclusion, despite the potential of hydrogen to contribute to the decarbonisation of many different sectors, one has to acknowledge that the deployment of hydrogen and fuel cells is only marginal today. To accelerate the commercial readiness of hydrogen technologies, the proposed Partnership is building on the work of FCH 2 JU which made the start of commercialisation of a first series of applications possible. It will aim at bringing a second series of applications to commercial level as outlined in the figure below.

It is also expected that the proposed Clean Hydrogen Partnership will improve through research and innovation the cost-effectiveness, reliability and quality of clean hydrogen applications developed in the EU and therefore accelerate and boost the market entry of these innovative competitive clean hydrogen solutions to support the decarbonisation of the EU economy

2.1.3. Specific objectives and targets

In order to have a good understanding of the hydrogen and fuel cells sector, it is worth looking at the KPIs listed in the Multi-Annual Work Plan of FCH 2 JU. One can see that a large number of KPIs are on track (in green in the table below) but that for a few applications technology developments are behind schedule. The case of PEM electrolyzers is of concern with current capital costs far from reaching the targets. This fact could delay large scale deployment of this technology with a direct consequence on clean hydrogen production.

It is also clear from this analysis that achieving the 2030 targets will be very challenging. However, there are reasons to remain optimistic if one looks for example at the capital costs of fuel cell buses. Continuous support from a series of FCH JU projects has allowed a drastic reduction of the costs of fuel cell buses, 400% in 15 years. A similar evolution could be expected for other hydrogen and fuel cell technologies.

KPIs FCH 2 JU Programme 2014-2020²

Transport – Demo (MAWP - SoA/Targets)									
Application	KPI	unit	SoA 2012	SoA 2017	FCH 2 JU Projects Results Average values 2018	2020	2024	2030	
Light Duty Vehicles (LDV)	Fuel cell system durability	h	2,500	4,000	5,000	5,000	6,000	7,000	
	Fuel cell system cost	EUR/kW	500	100	Work in progress	60	50	40	
Storage tanks	CAPEX Storage tank	EUR/kg H2	3,000	1,000	875	500	400	300	
Bus	Bus price	thousand EUR	1300	650	≈550. Latest figures from JIVE report	625 (150 units)	600 (250 units)	500 (300 units)	
HRS	CAPEX for the HRS	Thousand EUR/(kg/day)	7,5	7	2,978.53 (HRS bus)	4-2,1	3-1,6	2,4-1,3	
Energy – Demo Stationary Applications (MAWP - SoA/Targets)									
Application	KPI	unit	SoA 2012	SoA 2017	FCH 2 JU Projects Results Average values 2018	2020	2024	2030	

mCHPs	CAPEX	EUR/kW	16000	13000	16,000 (range 6,000-23,000)	10000	5500	3500
	Lifetime	years of appliance operation	10	12	12.25	13	14	15
	Durability	h	25,000	40,000	55,450	50,000	60,000	80,000
	Electrical Efficiency	% LHV	30-60	33-60	47.4 (between 37 and 60%)	35-60	37-63	39-65
	Medium Scale applications	CAPEX	EUR/kW	6,000 - 10,000	5,000 - 8,500	Work in progress for commercial applications	4.500 - 7.500	3.500 - 6.500
Large Scale Applications	Electrical efficiency	% LHV	45	45	48.3	45	45	50
	Lifetime	years of plant operation	2-20	6-20	15	8-20	8-20	15-20
	Availability	% of the plant	97	97	95	97	97	98
	Electrical efficiency	% LHV	40-45	41-55	50	42-60	42-62	50-65
Energy – H2 Production, Storage & Distribution (MAWP - SoA/Targets)								
Application	KPI	unit	SoA 2012	SoA 2017	FCH 2 JU Projects Results Average values 2018	2020	2024	2030
PEM electrolyzers	Electricity consumption @ nominal capacity	kWh/kg	60	58	58	55	52	50
	Capital cost	€/kg/d	8,000	2,900	≈ 8000	2,000	1,500	1,000
		(€/kW)	(~3,000)	(1,200)	EUR/(kg/d)	(900)	(700)	(500)
	O&M cost	€/kg/d/yr	160	58	No data	41	30	21
Alkaline Electrolyzers	Electricity consumption @ nominal capacity	kWh/kg	57	-	59 (minimum value 46) @System Level	50	49	48
	Capital cost	€/kg/d	8,000	1,600	Work in Progress	1,250	1,000	800
		(€/kW)	(~3,000)	(750)		(600)	(480)	(400)
	O&M cost	€/kg/d/yr	160	32	No data	26	20	16
Solid Oxide Electrolyzers	Electricity consumption	kWh/kg	na	41	2020 Target achieved	40	39	37
	Availability	%	na	na	≈66% Targets have not been achieved (79 @ Stack level)	95%	98%	99%
		Capital cost	€/kg/d	na	12,000	11,000 1,500 at mass production	4,500	2,400

	O&M cost	€/(kg/d)/yr	na	600	No data	225	120	75
Compressed gas tube trailers	Capacity	kg	400	850	No data	1000	1000	1000
	Capital cost	€/kg	550	400	No data	350	350	350
Large scale H2 storage	€/kg	1.2	1.1	1.0	No data		0.8	0.6

¹ There is no data available on installed electrolyser's capacity. The overall figure sums up the figures reported in the press.
